middle of March, and at the breaking up of the ice in spring sometimes rises 29 feet. The city is intersected by the sluggish and dirty Park river, which is spanned by 10 bridges. A covered toll bridge, 1000 feet long, across the Connecticut river connects the city with East Hartford. There are about 80 miles of streets, mostly lighted with gas, well drained, and macadamized or paved, and running north-and-south or east-and-west with considerable regularity. The city is for the most part compactly built of brick, granite, and freestone,—the public buildings and those of many private corporations being elegant and substantial. The old State-house, a Doric edifice, completed in 1795, has become the city-hall, while the State, since 1879, occupies a capacious new building of white marble in the modern Gothic style, costing over \$3,100,000, and standing conspicuously in the midst of the city on a slight elevation at the south side of Bushnell Park (a beautiful area of 46 acres). There are also in the city three other public squares. Of the seven cemeteries the most noteworthy is Cedar Hill, in the south-west part of the town, comprising 268 acres. Wadsworth's tower on Talcott mountain, to the north-west, affords one of the finest views in New England. Hartford is a healthy city, and its mean annual temperature is 50° Fahr. The area of the city is 10 square miles; and the population in 1870 was 37,180, of whom 10,817 were foreigners. A careful estimate of the population in 1879 gives nearly 50,000.

The city is divided into 8 wards, and is governed by a mayor and 16 aldermen elected biennially, and 32 councilmen elected annually. The water supply is from four reservoirs in West Hartford, with a capacity of 1,208,450,367 gallons. In 1873 a free public bathing-house was established. Since 1864 the city has had a paid fire-department, and now has seven steam fire-engines and a fire-alarm telegraph with 26 miles of wire. The total real estate and personal property in the city assessed for taxation, October 1, 1878, was \$44,001,245. The debt of the town in 1879 was \$1,298,158, and of the city \$2,152,308.

The principal business of the city is insurance. In 1879 there were 9 fire insurance companies, with assets of \$19,104,603; 8 life insurance companies, with assets of \$101,101,368; and 1 accident insurance company, with assets, \$1,170,163. There were 16 banks and trust companies, with an aggregate capital of over \$8,000,000, and 4 savings banks, with deposits, October 1, 1878, amounting to \$9,528,893. There are also, exclusive of railroads, 73 mechanical and manufacturing corporations, though several of the larger ones have their works in adjacent towns. These have a capital of \$17,347,000, and some of them a world-wide reputation, as the Colt Firearms Company, with works occupying grounds of 123 acres reclaimed by an extensive dike along the Connecticut river. They also include carpet, linen, and silk works, and a manufactory of edgetools. The publication of books too is a considerable interest. A very important branch of trade is the sale of leaf tobacco, which is the chief crop of the Connecticut river valley.

In 1879 there were 36 churches and 15 chapels of all denominations, including a fine Jewish synagogue. Here, too, is the seat of the Roman Catholic bishop, and the headquarters, in the United States, of the Chinese educational commission. Beside the 17 public schools and school-houses, which have cost \$1,032,000, and with their 163 teachers and 7680 pupils cost about \$200,000 a year, there were in 1879 43 educational and charitable corporations, several of them of notable importance, especially Trinity College (Episcopal), founded in 1823 as Washington College, which now has beautiful and commodious buildings in the south part of the city; the Theological Institute of Connecticut (Congregational), founded in 1834; the Hartford high and grammar school, founded 1655, the oldest educational institution in the State, and occupying one of the finest school edifices in the country; the Watkinson library of reference, with 34,000 volumes; the rooms and library of the Connecticut historical society, with its valuable collections of relics, books, and MSS.; the young men's institute, a circulating library of 27,000 volumes (the last three, with a picture gallery, occupy a roomy and accessible building known as the Wadsworth Athenaeum); the very complete State law library at the State-house; the American asylum for the

deaf and dumb, retreat for the insane, Hartford hospital and orphan asylum (see CONNECTICUT, vol. vi. p. 287). Thomas Green in 1764 opened the first printing-office in the city, and established the *Connecticut Courant*, which has ever since been regularly published. There were in 1879 three daily newspapers, seven weekly, and four monthly. In 1797 A. Kinsley exhibited the first steam locomotive in Hartford streets; and a portion of the Hartford and New Haven railroad was in operation in 1838. The railroads, however, have not been pecuniarily successful, that to New York being the only one of those meeting at Hartford which is in a prosperous condition.

Hartford was known to the aborigines as Suckiang; it was first permanently settled in 1635 by emigrants from eastern Massachusetts, and called Newtown. In 1637 it was named Hartford after Hertford in England. The Dutch had built a fort there in 1633, but it passed wholly into English hands in 1654. The first town meeting was held in 1635, and the first place of worship built, and school put in operation, in 1638. In 1639 was written at Hartford the constitution for the colony, the first framed in America, and embodying the characteristic features of all which follow. The first code of laws was drawn up in 1650, reducing the capital offences from 160 under English law to 15. In 1687 Sir E. Andros came to Hartford while the assembly was in session, and demanded the charter, but it was concealed in the notorious Charter Oak by Captain Joseph Wadsworth, and remained hidden till 1689. The historic tree survived till 1856. The city was incorporated in 1784, and in 1785 it became the sole capital of Connecticut.

HARTIG, GEORG LUDWIG (1764–1836), a German writer on forestry, was born at Gladenbach near Marburg, 2d September 1764. After obtaining a practical knowledge of forestry from his uncle at Harzburg, he studied from 1781 to 1783 at the university of Giessen. In 1786 he became inspector of forests to the prince of Solms-Braunfels at Hungen in the Wetterau, where he founded a school for the teaching of forestry. After obtaining in 1797 the appointment of inspector of forests to the prince of Orange-Nassau, he continued his school of forestry at Dillenburg, where its attendance considerably increased. On the dissolution of the principality by Napoleon I. in 1805 he lost his situation, but in 1806 he went as chief superintendent of forests to Stuttgart, whence in 1811 he was called to Berlin as principal superintendent of forests under the Prussian Government. There he again opened his institution for instruction in forestry, and succeeded in connecting it with the university of Berlin, where in 1830 he was named honorary professor. He died at Berlin 2d February 1836.

Hartig was the author of a number of valuable works on forestry, new editions of which have been published by his son Theodor. The principal of these works are *Lehrbuch für Jäger*; *Lehrbuch für Förster*; *Kubiktabellen für geschüttene, beschlagene, und runde Hölzer*; and *Lexikon für Jäger und Jagdfreunde*.

HARTLEPOOL, and WEST HARTLEPOOL, respectively a municipal borough and a town of England, county of Durham, and included in the parliamentary borough of the Hartlepoons, are situated the one on the north and the other on the south side of Hartlepool Bay, about a mile apart, but having connexion by railway, and practically forming portions of one town. By railway Hartlepool is 10 miles and West Hartlepool 12 miles N.N.E. of Stockton-on-Tees. The principal buildings of Hartlepool are the parish church, in the Early English style, dedicated to St Hilda; the borough hall, in the Italian style, erected in 1866, behind which there is a large market; the Durham militia artillery depôt, erected in 1861; the temperance hall, the mechanics' institute, and the theatre. New schools for boys, girls, and infants have been erected by the school board; and Prissick's schools, founded in 1826, have been constituted elementary schools under the Education Act of 1870. Among the other schools are Crook's endowed school, founded in 1755, and the school in connexion with Henry Smith's charity. The town was originally surrounded by walls, of which considerable remains may yet be seen. It is well supplied with water. The principal buildings of West Hartlepool are the ath-

œnum, the town-hall, the exchange, in the Gothic style, erected in 1875 at a cost of £10,000, the mechanics' institute, and the theatre. A Government school of art was established in 1874. The manufactures of the two towns are very much alike: they possess iron-works, puddling furnaces, brass and iron foundries, engine and boiler works, sawmills, cement works, tile works, and breweries. With the addition of the new docks, completed in 1879, the dock area between the towns is 86 acres, besides which there are ponds with an area of about 80 acres. Considerable difficulty has been found in maintaining a sufficient depth of water at the harbour bar of Hartlepool, and although the use of a powerful dredge has been so far effectual, it is probable that the only adequate remedy will be the extension of the breakwater. A large lighthouse for guiding the entrance of vessels was erected in 1846-47 at a cost of nearly £6000. In the shipping returns Hartlepool and West Hartlepool are classed together as one port; in 1878 the number of vessels that entered the port, including those in ballast, was 4640, with a tonnage of 885,762; the number that cleared 4662 with a tonnage of 992,370. For the five years ending 1878 the average number of vessels that entered was 5371, with a tonnage of 975,039, while 5447 cleared, with a tonnage of 1,005,740. The principal exports are coal, coke, machines, and cotton, linen and woollen goods, and the principal imports, timber, cattle, corn, provisions, and wool. The fisheries are considerable. The town is much resorted to in summer for sea-bathing. Several caverns, which may be explored for nearly fifty yards, have been excavated by the sea out of the rocks on the shore of the peninsula. The parliamentary borough of the Hartlepoles has an area of 7267 acres, and besides Hartlepool includes Stranton (in which parish West Hartlepool is situated), Seaton Carew, and Throston. Its population in 1861 was 27,475, and in 1871, 38,203. The population of the municipal borough of Hartlepool in 1861 was 12,245, and in 1871, 13,166; and the population of Stranton in 1861 was 13,601, and in 1871, 22,166.

The name Hartlepool means the pool or lake of Hart. The town grew up round a monastery which had St Hilda as its abbess, and the harbour was of some consequence as early as 1171. In the 13th century Hartlepool belonged to the Bruces of Annandale in Scotland, the progenitors of the royal family of that name. The town was erected into a borough about 1200. After Bruce ascended the Scottish throne his English possessions were forfeited, and Hartlepool was granted to the Cliffords. It suffered severely from the Scots in 1312, and again in 1315 after the battle of Bannockburn. During the great northern rebellion in the reign of Elizabeth it was seized by the insurgents. In 1644 it was taken by the Scottish army, and it remained in the possession of Scotland till 1647. West Hartlepool was founded in 1844 by Mr R. W. Jackson, the first M.P. for the borough of the Hartlepoles. Its first dock was constructed in 1847, after which it increased with great rapidity.

HARTLEY, DAVID (1705-1757), who may justly be called the founder of the English Association school of psychologists, was born on the 30th August 1705. His father, who was vicar of Armley in Yorkshire, wished him to enter the church; and with this view he was sent at the age of fifteen to Jesus College, Cambridge, where he studied under Saunderson the mathematician, and distinguished himself so much that he was elected a fellow of his college. But his university career so far modified his opinions that, feeling himself no longer able conscientiously to sign the Thirty-nine Articles, he abandoned his first intention and devoted himself to the study of medicine. He, however, remained in the communion of the English Church, living on intimate terms with the most distinguished churchmen of his day, among whom may be named Joseph Butler, Warburton, Law, Hoadley, and the poet Young. Indeed he asserted it to be a duty to obey ecclesiastical as well as civil authorities. The doctrine to which he most strongly

objected was that of eternal punishment. His keen interest in theology is proved by the fact that he devoted a large part of his *Observations* to that subject, the objective side of which he treated upon orthodox lines. The life of Hartley was the useful life of a benevolent and studious physician. He practised at Newark, Bury St Edmunds, London, and lastly at Bath, where he died on the 28th August 1757, within two days of his fifty-second birthday. It was at the age of twenty-five that he commenced the series of essays that was to make up his *Observations on Man: his Frame, his Duty, and his Expectations*. The praise of originality cannot be denied him. It is noteworthy, however, that very nearly at the same time with the publication of Hartley's *Observations* (1749), two works appeared in French expounding theories essentially similar to his—Condillac's *Traité sur l'Origine der Connoissances humaines* (1746) and the *Traité Analytique de l'Âme* by Charles Bonnet of Geneva, whose coincidence with Hartley in the most distinctive features of his philosophy is extremely remarkable. But Hartley's own account of the matter is so straightforward as to command immediate assent. His physical theory, he tells us, was drawn from certain speculations as to nervous action which Newton had published in his *Principia*. His psychological theory was suggested by an *Essay on the Fundamental Principle of Virtue or Morality* (written by a clergyman named Gay, and prefixed by 'Law' to his translation of Archbishop King's Latin work on the *Origin of Evil*), the chief object of which was to show that sympathy and conscience are developments by means of association from the selfish feelings. It is greatly to Hartley's credit that he so frankly owned his obligations to a work so far inferior to his own in completeness and tone of thought.

The outlines of Hartley's theory are, as follows. With Locke he asserted that, prior to sensation, the human mind is a blank. By a growth from simple sensations those states of consciousness which appear most remote from sensation come into being. And the one law of growth of which Hartley took account was the law of contiguity, synchronous and successive. By this law he sought to explain, not only the phenomena of memory; which others had similarly explained before him, but also the phenomena of emotion, of reasoning, and of voluntary and involuntary action.

By his physical theory Hartley gave the first strong impulse to the modern study of the intimate connexion of physiological and psychical facts which has proved so fruitful, though his physical theory in itself is inadequate, and has not been largely adopted. He held that sensation is the result of a vibration of the minute particles of the medullary substance of the nerves, to account for which he postulated, with Newton, a subtle elastic ether, rare in the interstices of solid bodies and in their close neighborhood, and denser as it recedes from them. Pleasure is the result of moderate vibrations, pain of vibrations so violent as to break the continuity of the nerves. These vibrations leave behind them in the brain a tendency to fainter vibrations or "vibratuncles" of a similar kind, which correspond to "ideas of sensation." Thus memory is accounted for. The course of reminiscence and of the thoughts generally, when not immediately dependent upon external sensation, is accounted for on the ground that there are always vibrations in the brain on account of its heat and the pulsation of its arteries. What these vibrations shall be is determined by the nature of each man's past experience, and by the influence of the circumstances of the moment, which causes now one now another tendency to prevail over the rest. Sensations which are often associated together become each associated with the ideas corresponding to the others; and the ideas corresponding to the associated sensations become associated together, sometimes so intimately that they form what appears to be a new simple idea, not without careful analysis resolvable into its component parts.

Starting, like the modern Associationists, from a detailed account of the phenomena of the senses, Hartley tries to show how, by the above laws, all the emotions; which he analyses with considerable skill, may be explained. Locke's incomplete phrase "association of ideas" is employed throughout, "idea" being taken as including every mental state but sensation. He emphatically asserts the existence of pure disinterested sentiment, while declaring it to be a growth from the self-regarding feelings. Voluntary action is explained as the result of a firm connexion between a motion and a sensation or "idea," and, on the physical side, between an "ideal" and a motory vibration. Therefore in the Free-will con-

troversy Hartley took his place as a Determinist. It is singular that, as he tells us, it was only with reluctance, and when his speculations were nearly complete, that he came to a conclusion on this subject in accordance with his theory.

Hartley's theory of reasoning is forced into agreement with the rest of his system. He declares that "assent and dissent, whatever their precise and particular nature may be, must come under the notion of ideas, being only those very complex internal feelings which adhere by association to such clusters of words as are called propositions. . . . And thus a mathematical proposition is nothing more than a group of ideas united by association," this group of ideas including "not only the sum of the ideas belonging to the terms of the proposition, but also those which belong to equality, coincidence, and truth."

The remaining half of the *Observations* is devoted to discussion of theological questions and to practical ethics, and does not call for detailed notice. While emphatically asserting his faith in supernatural religion, in the psychological part of his work he treats, not only conscience, but also the religious emotions entirely as developments from sensation, in the same sense as the pleasures of imagination.

Clearness, freedom from redundancy, and a severe simplicity and brevity are the best characteristics of his style. "No book," writes Sir James Mackintosh, "perhaps exists which, with so few of the common allurements, comes at last so much to please by the picture it presents of the writer's character. . . . Whoever bestows a careful perusal on the work must be unfortunate if he does not see, feel, and own that the writer was a great philosopher and a good man." (T. M. W.)

HARTLIB, SAMUEL (c. 1600–1662) was born towards the beginning of the 17th century at Elbing in Prussia, his father being a refugee from Poland. His mother was English. About 1628 Hartlib came to England, where he carried on a mercantile agency, and at the same time found leisure to enter with interest into the public questions of the day. An enthusiastic admirer of Comenius, he published in 1637 his *Conatum Comenianorum Præudia*, and in 1639 *Comenii Pansophicæ Prodromus et Didactica Dissertatio*. In 1641 appeared his *Relation of that which hath been lately attempted to procure Ecclesiastical Peace among Protestants*, and *A Description of Macaria*, containing his ideas of what a model state should be. During the civil war Hartlib occupied himself with the peaceful study of agriculture, printing at his own expense several treatises by others on the subject. In 1650 he issued the *Discourse of Flanders Husbandry* by Sir Richard Weston; and in 1651 his *Legacy, or an Enlargement of the Discourse of Husbandry used in Brabant and Flanders*, by Robert Child (see AGRICULTURE, vol. i. p. 297). For his various labours Hartlib received from Cromwell a pension of £100, afterwards increased to £300, as he had spent all his fortune on his experiments. He planned a school for the sons of gentlemen, to be conducted on new principles, and this probably was the occasion of his friend Milton's *Treatise on Education*, addressed to him in 1644, and of Sir William Petty's *Two Letters* on the same subject, in 1647 and 1648. His own literary labours were mostly confined to prefaces and short essays. Blythe, a contemporary, says that Ad. Speed, while engaged on his *Improvements in Husbandry*, was lodged and entertained by Samuel Hartlib. At the Restoration Hartlib lost his pension, which had already fallen into arrears; he petitioned parliament for a new grant of it, but what success he met with is unknown, as his latter years and death are wrapped in obscurity. 1662 has been assigned as the probable year of his death, as the latest of his extant letters bears that date.

His other publications are the following:—*Considerations tending to England's Reformation in Church and State*, 1647; *Vindication of Mr John Durie*, 1650; *Twisse's Doubting Conscience Resolved*, 1652; *A true and ready way to learn the Latin Tongue*, 1654; *The Reformed Commonwealth of Bees, and the Reformed Virginian Silkroom*, 1655; and *The Compleat Husbandman*, 1659. See *Biographical Memoir of Samuel Hartlib*, by H. Dircks, 1865; *Gentleman's Magazine*, January 1802; *Warton's Milton*; *Hartley's Agricultural Essays*; *Donaldson's Agricultural Biography*; and *Masson's Milton*.

HARTMANN, MORITZ (1821–1872), a German poet and novelist, was born of Jewish parents at Duschnik in Bohemia, October 15, 1821. He studied at Prague and Vienna, and after a tour in Italy, Switzerland, and South Germany became a teacher in Vienna. He left Austria, however, in 1844, in order to publish without danger a volume of patriotic poems entitled *Kelch und Schwert*, which appeared at Leipsic in 1845, and in which he gave expression to somewhat radical sentiments as regards both church and state, in language full of the fire of youthful passion and tinged with considerable poetic fancy. After residing for some years in Belgium and France, he came to Leipsic, where in 1847 he published *Neuere Gedichte*. On his venturing towards the close of this year to return to Austria he suffered a short imprisonment, from which he was freed by the revolution of the following March. In the same year he was chosen to represent the district of Leitmeritz in the Frankfort parliament, where he took his seat on the extreme left. In October he accompanied Blum and Fröbel to Vienna, but he made his escape before the execution of Blum, and took part in the deliberations of the "Rump Parliament" at Stuttgart. In 1849 he published the *Reimchronik des Pfaffen Maurizius*, a satirical political poem in the style of the old chronicles. After the dissolution of the "Rump Parliament," he went to Switzerland, then to England and Ireland, and in 1850 to Paris, where, besides other literary engagements, he held that of correspondent to the *Kölnische Zeitung*. On the outbreak of the Russian war he became correspondent of the same paper in the Crimea, where he remained eighteen months. After several years' residence at Paris he settled in 1860 at Ghent, where he delivered courses of lectures on German literature and history in some of the principal academies. In 1863 he removed to Stuttgart to edit the *Freyc*, and in 1868 he undertook the editorship at Vienna of the *Neue Freie Presse*. He died at Oberdöbling near Vienna, May 13, 1872. Hartmann published several volumes of poems in addition to those already mentioned, and besides his spirited accounts of his travels and adventures he is the author of various novels of more than average merit. A series of tales (*Novellen*, 3 vols.) appeared in 1863, and a second series (*Nach Natur*, 3 vols.) in 1866. His collected works were published at Stuttgart in 10 vols., 1873–74, and a selection of his poems at the same place in 1874.

HARTMANN VON AUE, a Middle High German poet, was born about 1170. He was of knightly rank, and held a fief at Aue, which was probably on the upper Neckar. He seems to have been educated in a monastery, and was able to read and write. Among his accomplishments was a knowledge of French, and as he took part in the third crusade he must be considered to have passed under the influences which were in his time most favourable to poetic impulse. Although his lyrics are not without merit he excels chiefly in narrative poetry; and the best known of his narrative poems, which was also one of the earliest, is *Der arme Heinrich* ("Poor Henry"). Some of the incidents of this tale are exceedingly repulsive, but others are marked by delicate grace and pathos. Two other tales, *Erec* and *Iwein*, the former written before 1197 and the latter before 1204, treat of the Arthurian legend, and are based upon French poems by Chrétien de Troies. The story of each is clearly conceived, and the diction is fresh, harmonious, and animated. Hartmann has neither the exquisite finish and charm of Gottfried of Strasburg nor the soaring imagination of Wolfram von Eschenbach; but he stands next to these supreme mediæval writers in the power of giving artistic shape to strong feeling. He is mentioned as alive in 1207 by Gottfried of Strasburg, but in 1220 his death is deplored by Heinrich von dem Türlin in the *Krone*.

Each of his works has found a special editor; and a complete edition of his writings has been issued by F. Bech in the *Deutsche Classiker des Mittelalters*. See L. Schmid, *Stand, Heimat, und Geschlecht des Minnesängers Hartmann* (1874).

HARTSHORN, SPIRITS OF, a name signifying originally the ammoniacal liquor obtained by the distillation of horn shavings, afterwards applied to the partially purified similar products of the action of heat on nitrogenous animal matter generally, and now popularly used to designate solution of ammonia. See **AMMONIA**, vol. i. p. 741, and **CHEMISTRY**, vol. v. p. 509.

HARUN ER RASHID. See **HAROUN AL RASCHID**.

HARUSPICES (literally entrail-observers, cf. Skt. *hila*, Gr. *χορδή*), a class of soothsayers in Rome. Their art consisted especially in deducing from the appearance presented by the entrails of the slain victim the will of the gods. They also interpreted all portents or unusual phenomena of nature, especially thunder and lightning, and prescribed the expiatory ceremonies after such events. To please the god, the victim must be without spot or blemish, and the practice of observing whether the entrails presented any abnormal appearance, and thence deducing the will of heaven, was also very important in Greek religion. This art, however, appears not to have been, as some other modes of ascertaining the will of the gods undoubtedly were, of genuine Aryan growth. It is foreign to the Homeric poems, and must have been introduced into Greece after their composition. In like manner, as the Romans themselves believed, the art was not indigenous in Rome, but derived from Etruria. The Etruscans were said to have learned it from a being named Tages, grandson of Jupiter, who had suddenly sprung from the ground near Tarquinii. The art was practised in Rome chiefly by Etruscans, seldom by native-born Romans who had studied in the priestly schools of Etruria. Though it was of great importance under the early republic, it never became a part of the state religion. In this respect the haruspices ranked lower than the augurs; the latter were a more ancient and purely Roman institution, and were a most important element in the political organization of the city. In later times the art fell into disrepute, and the saying of Cato the censor is well known, that he wondered one haruspex could look another in the face without laughing (Cic., *De Div.*, ii. 24). Under the empire, however, we hear of a regular collegium of sixty haruspices; and Claudius is said to have tried to restore the art and put it under the control of the pontifices.

HARVARD COLLEGE, the earliest institution of learning in the United States and on the continent of North America. The record gives its origin thus. The English colonists on Massachusetts Bay, settling at what is now Boston in 1630, began a plantation the next year three miles up Charles River, which they called "New Towne." The colony court of September 1636 "agreed to give £400," which exactly doubled the public tax for the year, "towards a schoole or collidge, whereof £200 to be paid the next year, and £200 when the work is finished, and the next court to appoint where and what building." In November 1637 "the Colledge is ordered to be at New Towne," the name of which had been changed to Cambridge, and a committee was appointed "to take order" for it. In March 1638-39 "it is ordered that the colledge agreed upon formerly to bee built at Cambridge shalbee called Harvard Colledge." The reason was that the Rev. John Harvard, B.A. 1632, and M.A. 1635, of Emmanuel College, Cambridge, England, dying in Charlestown, Massachusetts, September 14, 1638, by will left half his estate, about £800, and his library, to the wilderness seminary. The college charter of 1650 declared the object to be "the

education of the English and Indian youth of this country in knowledge and godlynes." The first brick edifice on the college grounds, having rooms for twenty of the aborigines, was called "the Indian college." In it was printed the apostle Eliot's translation of the Bible into the language of the natives, with primers, grammars, tracts, &c. Several of the natives were members of the college; only one graduated from it. By generous aid received from abroad for this special object, the college was greatly helped in its infancy.

Thus from the beginning private munificence rather than the public treasury fostered and sustained the college, and with steadily increasing preponderance all through its history have its supplies and endowments come from the generosity of individuals. Grants from the colony, province, and State, of small sums for salaries and incidental purposes, made annually or at intervals, wholly ceased more than sixty years ago. With scarce an exception all the present invested funds of the college and of its professional schools, amounting to \$3,615,538.87, with the halls, library, and apparatus, are the benefactions of its friends.

The charter constitutes as a corporation a president, treasurer, and five fellows, who initiate all measures concerning the college, hold its funds, and have the nomination for filling vacancies in their own body, as also of all the officers for instruction and for the internal government of the institution in all its departments, subject, however, to the advice and approval and final action of a board of overseers. The State, claiming as founder and patron, till quite recently regarded the college as a State institution, over which it should exercise a direct control through the legislature and the executive, by its authority in the membership and the election of the whole or a part of the board of overseers. Various modifications made from time to time in the composition or method of choice of the members of this board not relieving the controversies and embarrassments incident to legislative action, which proved prejudicial to the best interests of the college, its organic connexion with the State by this tie was severed by statute in 1866. The board of overseers as now constituted is composed of thirty of the alumni, besides the president and the treasurer, elected by the ballots of the alumni on commencement day at the college, in sections of five, serving a term of six years. With its complement of professional schools of law, medicine, theology, science, and many special departments of the latter, more than any other institution in America, and with but a few gaps yet to be filled in its completeness of method and equipment to bring it to comparison with foreign institutions of learning, Harvard College may claim to be in the most comprehensive sense of the term a university, a title which is, indeed, assumed, and generally applied to it. Recent changes in the course of study in the college have allowed a wide range for elective studies to undergraduates, the proportions being, one-fourth obligatory, three-fourths elective. In the professional schools most of the studies are obligatory. The number of bound volumes in the library and schools is 232,200. The number of halls owned and occupied for college uses is twenty-nine of brick or stone, including ten for students' chambers. The whole number of professors, instructors, &c., in all departments, is 135; of librarians, proctors, and other officers in the service of the college, 28. The number of the alumni of the college proper about 9600; the number in all departments about 14,000.

HARVEST-BUG, a name erroneously applied to the hexapod larval condition of a mite, not one of the *Insecta*, but belonging to the division *Acaridea* of the class *Arachnida*. It is very small, of a brick-red colour, and swarms both among wild vegetation and cultivated plants, especi-

ally near the sea, attaching itself, however, on the first opportunity to the bodies of human beings, hares, dogs, cats, and other mammals, and even insects. On reaching the skin, it rapidly burrows deeply into it, causing a painful itching, followed by a swelling of irritation and size varying with the individuals attacked, and enduring for several days. It is usually at the end of July or in August that these mites make their appearance; and the frequency with which they attach themselves to the lower extremities of people walking in fields at harvest-time has given rise to their trivial name. The effect of their subcutaneous presence varies in different people, as above mentioned; in some it assumes so intensely painful an aspect as to originate a disease called autumnal erythema. Such severity of symptoms is generally found in warmer climates than that of Great Britain; the mite however is plentiful, and causes much annoyance, in Scotland. Extraction with a fine needle, under a magnifying power, is the best way to get rid of the pests; but the application of a solution of carbolic acid, benzine, sulphur ointment, or any other powerful and easily diffused insecticide agent will usually soon destroy them.

The scientific name of this creature is *Acarus* (*Leptus* or *Tetranychus*) *autumnalis*, and in France it has received various common names, that of "rouget" being the best known. It has been placed in different genera by modern authors, who have hitherto considered it as a fully developed form, of somewhat doubtful affinities. The old naturalist Degeer appears to have suspected its correct status as an imperfect *Acarus*; but it has been reserved for the French naturalist, M. P. Méguin, to prove from actual observation the fact that it is only the larva of a well-known mite, *Trombidium holosericeum*, a silky bright scarlet species often found in spring and early summer in gardens and fields. This distinguished biologist has in like manner put beyond doubt the identity of various other members of the *Acaridea*, hitherto dissociated. In April he found both sexes of the perfect mite, but at the end of May and in June only gravid females occurred. These in June and July deposited their eggs, from which was hatched the creature heretofore known as *Acarus* (or *Leptus*) *autumnalis*. As soon as this has implanted its mandibles into the skin of the individual attacked, its abdomen dilates perceptibly, finally becoming about five times as large as on leaving the egg, though the cephalothorax and limbs remain unchanged. It turns to an octopod nymph, or pupa; and after hibernation, during which the nutritive fluids imbibed in the parasitic stage are assimilated, the adult stage of a purely phytophagous *Trombidium*, capable of reproduction, is reached.

There seems every reason to believe that the skin irritation caused in Mexico by a supposed insect, called *Thalsahuate* or *Thalsahuate* by the Indians, is really produced by this or a closely allied mite. Similar complaints are apparently caused by mites in Brazil, Martinique, Honduras, &c.; and the symptoms are naturally aggravated in such tropical localities.

An account, with figures, of all the stages of *Trombidium holosericeum* and the allied *T. fuliginosum* (of which the octopod *T. phalangii*, parasitic upon very long-legged spiders, is the nymph or pupa) will be found in the *Annales des Sciences Naturelles*, 6^{me} série, iii. (1876), article No. 5, by M. Méguin.

HARVEY, GABRIEL (1545-1630), an English writer of the Elizabethan period, was the eldest son of a rope-maker at Saffron Walden, and received his education at Christ's College and Pembroke Hall, Cambridge, where we find him about 1576-78 lecturing on rhetoric. Immediately afterwards he appears to have been sent abroad by his patron the earl of Leicester, to whom he refers in his *Gratulationum Waldensium libri quatuor* (Lond., 1578), a collection of pieces in honour of the queen's visit to Audley End, near his native town. In 1585 he became doctor of laws. Though Harvey expresses a desire to be "epitaphed the Inventour of the English Hexameter," his name, familiar enough to his more learned contemporaries, would probably have been well nigh forgotten had it not been for his friendship with Spenser and his hostilities with Greene and Nash. To the student of Spenser he is familiar as one of the poet's principal correspondents, and as the Hobbinol who wrote the poem prefixed to the "Faerie Queen." His quarrel with Greene and Nash was begun by Greene allud-

ing in his *Quip for an Upstart Courtier* (1592) to the fact that Harvey was the son of a rope-maker; and after Greene's death it raged with ever increasing violence until the archbishop of Canterbury issued an order for the seizure of all works written by either of the combatants.

Harvey's extant publications, which contain many minor matters of interest to the student of literature, are—*Ciceronianus*, London, H. Binnemann, 1577; *Rhetor, vel duorum dierum Oratio de Natura, Arte, et Exercitatione Rhetorica*, 1577; *Smithus vel Musarum Lachrymæ*, Lond., 1578, in honour of the scholarly Sir Thomas Smith; *Four Letters and certaine Sonnets, especially touching Robert Greene and other parties by him abused*, 1592; *Pierce's Supercroagation, or a new Prayse of the Old Asse*, 1593, reprinted, but inaccurately, by Mr Collier, 4to, 1863; *A new Letter of Notable Contents*, 1593; *The Trimming of Thomas Nash, Gentleman, by the high titled Don Ricardo de Medico Campo*, 1597, reprinted in *The Old Book Collector's Miscellany*, Lond., 1871. See Warton's *History of English Poetry*, Hazlitt's edition, and J. P. Collier's *Bibliographical and Critical Account of the Rarest Books in the English Language*, Lond., 1865, under "Harvey," "Nash," and "Greene."

HARVEY, SIR GEORGE (1806-1876), a Scottish painter and president of the Royal Scottish Academy, was the son of a watchmaker, and was born at St Ninians, near Stirling, in February 1806. Soon after his birth his parents removed to Stirling, where George was apprenticed to a bookseller. His love for art having, however, become very decided, he in his eighteenth year entered the Trustees' Academy at Edinburgh. Here he so distinguished himself that in 1826 he was invited by the Scottish artists, who had resolved to found a Scottish academy, to join it as an associate. Indeed it was chiefly to the zeal and judgment of Harvey and of two others that it owed its early success. Harvey's first picture, *A Village School*, was exhibited in 1826 at the Edinburgh Institution; and from the time of the opening of the Academy in the following year he continued annually to enrich its exhibitions by a succession of pictures which, although they never obtained much fame beyond the limits of Scotland, appealed with such effect to Scottish sentiment as to win for him in his native land an unrivalled popularity. His best known pictures are those depicting historical episodes in religious history from a puritan or evangelical point of view, such as *Covenanters Preaching*, *Covenanters' Communion*, *John Bunyan and his Blind Daughter*, *Sabbath Evening*, and the *Quitting of the Manse*. He was, however, equally successful in subjects not directly religious; and *The Bowlers*, *A Highland Funeral*, *The Curlers*, *A Schule Skailin'*, and *Children Blowing Bubbles in the Churchyard of Greyfriars, Edinburgh*, manifest the same close observation of character, artistic conception, and conscientious elaboration of details. In *The Night Mail* and *Dawn Revealing the New World to Columbus* the aspects of nature are made use of in different ways, but with equal happiness, to lend impressiveness and solemnity to human concerns. It was chiefly in his later years that he devoted his attention to landscape, the branch of art in which on the whole he was most successful, and there perhaps in suggesting the deep calm and the sweet and varied charm which broods among the hills when nature is at rest. He also devoted some attention to portraiture, among his works in this branch of art being a portrait of Professor Wilson, now at the Philosophical Institution, Edinburgh. In 1820 he was elected a fellow of the Royal Scottish Academy, and in 1864 he succeeded Sir J. W. Gordon as president. He received the honour of knighthood in 1867. His death took place at Edinburgh, January 22, 1876.

Sir George Harvey was the author of a paper on the "Colour of the Atmosphere," read before the Edinburgh Royal Society, and afterwards published with illustrations in *Good Words*; and in 1870 he published a small volume entitled *Notes of the Early History of the Royal Scottish Academy. Selections from the Works of Sir George Harvey, P.R.S.A., described by the Rev. A. L. Simpson, F.S.A. Scot., and photographed by Thomas Annan*, appeared at Edinburgh in 1890.

HARVEY, WILLIAM (1578-1657), the discoverer of the circulation of the blood, was the eldest son of Thomas Harvey, a prosperous Kentish yeoman, and was born at Folkestone on April 1, 1578. After passing through the grammar school of Canterbury, on the 31st of May 1593, having just entered his sixteenth year, he became a pensioner of Caius College, Cambridge; at nineteen he took his B.A. degree, and soon after, having chosen the profession of medicine, he went to study at Padua under Fabricius and Casserius (see ANATOMY, vol. i. pp. 809, 810). At the age of twenty-four Harvey became doctor of medicine, April 1602. Returning to England in the first year of James I., he settled in London; and two years later he married the daughter of Dr Lancelot Brown, who had been physician to Queen Elizabeth. In the same year Harvey became a candidate of the Royal College of Physicians, and was duly admitted a fellow (June 1607). In 1609 he obtained the reversion of the post of physician to St Bartholomew's Hospital. His application was supported by the king himself and by Dr Atkins, the president of the college. On the death of Dr Wilkinson in the course of the same year he succeeded to the post. He was thrice censor of the college, and in 1615 was appointed Lumleian lecturer. In the following year—the year of Shakespeare's death—he began his course of lectures, and first brought forward his views upon the movements of the heart and blood.¹ Meantime his practice increased, and he had the lord chancellor, Francis Bacon, and the earl of Arundel among his patients. In 1618 he was appointed physician extraordinary to James I., and on the next vacancy physician in ordinary to his successor. In 1628, the year of the publication of the *Exercitatio Anatomica de Motu Cordis et Sanguinis*, he was elected treasurer of the College of Physicians, but at the end of the following year he resigned the office, in order, by command of Charles I., to accompany the young duke of Lennox (James Stuart, afterwards duke of Richmond) on his travels. He appears to have visited Italy, and returned in 1632. Four years later he accompanied the earl of Arundel on his embassy to the emperor. He was eager in collecting objects of natural history, sometimes causing the earl anxiety for his safety by his excursions in a country infested by robbers after the Thirty Years' War. In a letter written on this journey, he says—"By the way we could scarce see a dog, crow, kite, raven, or any bird, or anything to anatomize; only some few miserable people, the reliques of the war and the plague, whom famine had made anatomies before I came." Having returned to his practice in London at the close of the year 1636, he accompanied Charles I. in one of his journeys to Scotland (1639 or 1641). While at Edinburgh he visited the Bass Rock; he minutely describes its abundant population of sea-fowl in his treatise *De Generatione*, and incidentally speaks of the then credited account of the solan goose growing on trees as a fable. He was in attendance on the king at the battle of Edgehill (October 1642), where he withdrew under a hedge with the prince of Wales and the duke of York (then boys of twelve and ten years old), "and took out of his pocket a book and read. But he had not read very long before a bullet of a great gun grazed on the ground near him, which made him remove his station," as he afterwards told Aubrey. After the indecisive battle, Harvey followed Charles I. to Oxford, "where," writes the same gossiping narrator, "I first saw him, but was then too young to be acquainted with so great a doctor. I remember he came several times to our college (Trinity) to George Bathurst, B.D., who had a hen

¹ A venerable MS. notebook in Harvey's own crabbed handwriting was discovered only lately in the British Museum, with the title "Prælectiones anatomicae," &c., this, so far as it has been deciphered, contains the germs of his great discovery.

to hatch eggs in his chamber, which they opened daily to see the progress and way of generation." In Oxford he remained three years, and there was some chance of his being superseded in his office at St Bartholomew's Hospital, "because he hath withdrawn himself from his charge, and is retired to the party in arms against the Parliament." It was no doubt at this time that his lodgings at Whitehall were searched, and not only the furniture seized but also invaluable manuscripts and anatomical preparations.²

While with the king at Oxford he was made warden of Merton College, but a year later, in 1646, that city surrendered to Fairfax, and Harvey returned to London. He was now sixty-eight years old, and, having resigned his appointments and relinquished the cares of practice, lived in learned retirement with one or other of his brothers. It was in his brother Daniel's house at Combe that Dr (afterwards Sir George) Ent, a faithful friend and disciple (1604-1689), visited him in 1650. "I found him," he says, "with a cheerful and sprightly countenance investigating, like Democritus, the nature of things. Asking if all were well with him—'How can that be,' he replied, 'when the state is so agitated with storms and I myself am yet in the open sea? And indeed, were not my mind solaced by my studies and the recollection of the observations I have formerly made, there is nothing which should make me desirous of a longer continuance. But thus employed, this obscure life and vacation from public cares which would disgust other minds is the medicine of mine.'" The work on which he had been chiefly engaged at Oxford, and indeed since the publication of his treatise on the circulation in 1628, was an investigation into the recondite but deeply interesting subject of generation. Charles I. had been an enlightened patron of Harvey's studies, had put the royal deer parks at Windsor and Hampton Court at his disposal, and had watched his demonstration of the growth of the chick with no less interest than the movements of the living heart. Harvey had now collected a large number of observations, though he would probably have delayed their publication. But Ent succeeded in obtaining the manuscripts, with authority to print them or not as he should find them. "I went from him," he says, "like another Jason in possession of the golden fleece, and when I came home and perused the pieces singly, I was amazed that so vast a treasure should have been so long hidden." The result was the publication of the *Exercitationes de Generatione* (1651).

This was the last of Harvey's labours. He had now reached his seventy-third year. His theory of the circulation had been opposed and defended, and was now generally accepted by the most eminent anatomists both at home and abroad. He was known and honoured throughout Europe, and his own college erected a statue in his honour (1652), "viro monumentis suis immortalis." In 1654 he was elected to the highest post in his profession, that of president of the college; but the following day he met the assembled fellows, and, declining the honour for himself on account of the infirmities of age, recommended the re-election of the late president Dr Prujean. He accepted,

² "Ignoscant mihi niveæ animæ, si, summorum injuriarum memor, levem gemitum effudero. Doloris mihi hæc causa est: cum, inter nuperos nostros tumultus et bella plusquam civilia, serenissimum regem (idque non solum senatus permissione sed et jussu) sequor, rapaces quædam manus non modo ædium mearum suppellectilem onerata expilarunt, sed etiam, quæ mihi causa gravior querimonie, adversaria mea, multorum annorum laboribus parata, e museo meo summovertunt. Quo factum est ut observationes plurimæ, præsertim de generatione insectorum, cum republica literariæ (ausim dicere) detrimento, penerint."

—*De Gen.*, Ex. lxxviii. To this loss Cowley refers—

"O cursed war! who can forgive thee this?
Houses and towns may rise again,
And ten times easier 'tis
To rebuild Paul's than any work of his."

however, the office of consiliarius, which he again held in the two following years. He had already enriched the college with other gifts besides the honour of his name. He had raised for them "a noble building of Roman architecture (rustic work with Corinthian pilasters), comprising a great parlour or conversation room below and a library above"; he had furnished the library with books, and filled the museum with "simples and rarities," as well as with specimens of instruments used in the surgical and obstetric branches of medicine. At last he determined to give to his beloved college his paternal estate at Burmarsh in Kent. His wife had died some years before, his brothers were wealthy men, and he was childless, so that he was defrauding no heir when, in July 1656, he made the transfer of this property, then valued at £56 per annum, with provision for a salary to the college librarian and for the endowment of an annual oration, which is still given on the anniversary of the day. The orator, so Harvey orders in his deed of gift, is to exhort the fellows of the college "to search out and study the secrets of nature by way of experiment, and also for the honour of the profession to continue mutual love and affection among themselves."

Harvey, like his contemporary and great successor Sydenham, was long afflicted with gout, but he preserved his activity of mind to an advanced age. In his eightieth year, on the 3d of June 1657,¹ he was attacked by paralysis, and though deprived of speech was able to send for his nephews and distribute his watch, ring, and other personal trinkets among them. He died the same evening, "the palsy giving him an easy passport," and was buried with great honour in his brother Eliab's vault at Hempstead in Essex, "annorum et famæ satur."

Aubrey, to whom we owe most of the minor particulars about Harvey which have been preserved, says—"In person he was not tall, but of the lowest stature; round faced, olivaster complexion, little eyes, round, very black, full of spirits; his hair black as a raven, but quite white twenty years before he died." The best portrait of him extant is by Cornelius Jansen in the library of the College of Physicians, one of those rescued from the great fire, which destroyed their original hall in 1666. It has been often engraved, and is prefixed to the fine edition of his works published in 1766.

Harvey's Work on the Circulation.—In estimating the character and value of the discovery announced in the *Exercitatio de Motu Cordis et Sanguinis*, it is necessary to bear in mind the previous state of knowledge on the subject. Aristotle taught that in man and the higher animals the blood was elaborated from the food in the liver, thence carried to the heart, and sent by it through the veins over the body. His successors of the Alexandrian school of medicine, Erasistratus and Herophilus, further elaborated his system, and taught that, while the veins carried blood from the heart to the members, the arteries carried a subtle kind of air or spirit. For the practical physician only two changes had been made in this theory of the circulation between the Christian era and the 16th century. Galen had discovered that the arteries were not, as their name implies, merely air-pipes, but that they contained blood as well as vital air or spirit. And it had been gradually ascertained that the nerves (*νεῦρα*) which arose from the brain and conveyed "animal spirits" to the body were different from the tendons or sinews (*σύνερα*) which attach muscles to bones. First, then, the physicians of the time of Linaero knew that the blood is not stagnant in the body. So did Shakespeare and Homer, and every augur

who inspected the entrails of a victim, and every village barber who breathed a vein. Plato even uses the expression τὸ αἷμα κατὰ πάντα τὰ μέλη σφοδρῶς περιφερόσθαι. But no one had a conception of a continuous stream returning to its source (a circulation in the true sense of the word) either in the system or in the lungs. If they used the word *circulatio*, as did Cæsalpinus,² it was as vaguely as the French policeman cries "Circulez." The movements of the blood were in fact thought to be slow and irregular in direction as well as in speed, like the "circulation" of air in a house, or the circulation of a crowd in the streets of a city. Secondly, they supposed that one kind of blood flowed from the liver to the right ventricle of the heart, and thence to the lungs and the general system by the veins, and that another kind flowed from the left ventricle to the lungs and general system by the arteries. Thirdly, they supposed that the septum of the heart was pervious and allowed blood to pass directly from the right to the left side. Fourthly, they had no conception of the functions of the heart as the motor power of the movement of the blood. They doubted whether its substance was muscular; they supposed its pulsation to be due to expansion of the spirits it contained; they believed the only dynamic effect which it had on the blood to be sucking it in during its active diastole, and they supposed the chief use of its constant movements to be the due mixture of blood and spirits.

Of the great anatomists of the 16th century, Sylvius (*In Hipp. et Gal. Phys. Partem Anatom. Isagoge*) described the valves of the veins; Vesalius (*De Humani Corporis Fabrica*, 1542) ascertained that the septum between the right and left ventricles is complete, though he could not bring himself to deny the invisible pores which Galen's system demanded. Servetus, in his *Christianismi Restitutio* (1553), goes somewhat further than his fellow-student Vesalius, and says—"Paries ille medius non est aptus ad communicationem et elaborationem illam; licet aliquid resudare possit;" and, from this anatomical fact and the large size of the pulmonary arteries he concludes that there is a communication in the lungs by which blood passes from the pulmonary artery to the pulmonary vein—"Eodem artificio quo in hepato fit transfusio a vena portæ ad venam cavam propter sanguinem, fit etiam in pulmone transfusio a vena arteriosa ad arteriam venosam propter spiritum." The natural spirit of the left side and the vital spirit of the right side of the heart were therefore, he concluded, practically the same, and hence two instead of three distinct *spiritus* should be admitted. It seems doubtful whether even Servetus rightly conceived of the entire mass of the blood passing through the pulmonary artery and the lungs. The transference of the *spiritus naturalis* to the lungs, and its return to the left ventricle as *spiritus vitalis*, was the function which he regarded as important. Indeed a true conception of the lesser circulation as a transference of the whole blood of the right side to the left was impossible until the corresponding transference in the greater or systemic circulation was discovered. Servetus, however, was the true predecessor of Harvey in physiology, and his claims to that honour are perfectly authentic and universally admitted.³

The way then to Harvey's great work had been paved by the discovery of the valves in the veins, and by that of the lesser circulation,—the former due to Sylvius and Fabricius, the latter to Servetus,—but the significance of the

² Indeed the same word, *περιφοράς αἵματος*, occurs in the Hippocratic writings, and was held by Van der Linden to prove that to the father of medicine himself, and not to Columbus or Cæsalpinus, belonged the laurels of Harvey.

³ Realdus Columbus (*De Re Anatomica*, 1559) formally denies the muscularity of the heart, yet correctly teaches that blood and spirits pass from the right to the left ventricle, not through the septum.

¹ This is the date usually given according to the college annals. Grainger's *Biographical History of England* makes it June 30; Hamey, a contemporary, June 15; while Dr Lawrence, following the inscription on the tomb, gives June 3, 1658.

valves was unsuspected, and the fact of even the pulmonary circulation was not generally admitted in its full meaning.

In his treatise Harvey proves (1) that it is the contraction, not the dilatation, of the heart which coincides with the pulse, and that the ventricles as true muscular sacs squeeze the blood which they contain into the aorta and pulmonary artery; (2) that the pulse is not produced by the arteries enlarging and so filling, but by the arteries being filled with blood and so enlarging; (3) that there are no pores in the septum of the heart, so that the whole blood in the right ventricle is sent to the lungs and round by the pulmonary veins to the left ventricle, and also that the whole blood in the left ventricle is again sent into the arteries, round by the smaller veins into the *venæ cavæ*, and by them to the right ventricle again—thus making a complete “circulation”; (4) that the blood in the arteries and that in the veins is the same blood; (5) that the action of the right and left sides of the heart, auricles, ventricles, and valves, is the same, the mechanism in both being for reception and propulsion of liquid and not of air, since the blood on the right side, though mixed with air, is still blood; (6) that the blood sent through the arteries to the tissues is not all used, but that most of it runs through into the veins; (7) that there is no to and fro undulation in the veins, but a constant stream from the distant parts towards the heart; (8) that the dynamical starting-point of the blood is the heart and not the liver.

The method by which Harvey arrived at his complete and almost faultless solution of the most fundamental and difficult problem in physiology has been often discussed, and is well worthy of attention. He begins his treatise by pointing out the many inconsistencies and defects in the Galenical theory, quoting the writings of Galen himself, of Fabricius, Columbus, and others, with great respect, but with unflinching criticism. For, in his own noble language, wise men must learn anatomy, not from the decrees of philosophers, but from the fabric of nature herself, “*nec ita in verba jurare antiquitatis magistræ, ut veritatem amicam in apertis relinquat, et in conspectu omnium deserant.*” He had, as we know, not only furnished himself with all the knowledge that books and the instructions of the best

but through the lungs, “*quod nemo hactenus aut animadvertit aut scriptum reliquit.*” The fact that Harvey quotes Columbus and not Servetus is explained by the almost entire destruction of the writings of the latter, which are now among the rarest curiosities. The great anatomist Fabricius, Harvey’s teacher at Padua, described the valves of the veins more perfectly than had Sylvius. Ruini, in his treatise on the *Anatomy and Diseases of the Horse* (1590), taught that the left ventricle sends blood and vital spirits to all parts of the body except the lungs—the ordinary Galenical doctrine. Yet on the strength of this phrase Professor Ercolani has actually put up a tablet in the veterinary school at Bologna to Ruini as the discoverer of the circulation of the blood! The claims of Cæsalpinus, a more plausible claimant to Harvey’s laurels, are scarcely better founded. In his *Questiones Peripateticæ* (1571) he followed Servetus and Columbus in describing what we now know as the pulmonary “circulation” under that name, and this is the only foundation for the assertion (first made in Bayle’s dictionary) that Cæsalpinus knew “the circulation of the blood.” He is even behind Servetus, for he only allows part of the blood of the right ventricle to go round by this “circuit”; some, he conceives, passes through the hypothetical pores in the septum, and the rest by the superior cava to the head and arms, by the inferior to the rest of the body—“*Hanc esse venarum utilitatem ut omnes partes corporis sanguinem pro nutrimento deferant. Ex dextro ventri cordis vena cava sanguinem crassiorem, in quo calor intensus est magis, ex altero autem ventri, sanguinem temperatissimum ac sincerissimum habente, egreditur aorta.*” Cæsalpinus seems to have had no original views on the subject; all that he writes is copied from Galen or from Servetus except some erroneous observations of his own. His greatest merit was as a botanist; and no claim to the “discovery of the circulation” was made by him or by his contemporaries. When it was made, Haller decided conclusively against it. The fact that an inscription was lately placed on the bust of Cæsalpinus at Rome, which states that he preceded others in recognizing and demonstrating “the general circulation of the blood,” is only a proof of the blindness of misplaced national vanity.

anatomists of Italy could give, but, by a long series of dissections, had gained a far more complete knowledge of the comparative anatomy of the heart and vessels than any contemporary—we may almost say than any successor, until the times of Hunter and Meckel. Thus equipped, he tells us that he began his investigations into the movements of the heart and blood by looking at them—*i.e.*, by seeing their action in living animals. After a modest preface, he heads his first chapter “*Ex vivorum dissectione, qualis sit cordis motus.*” He minutely describes what he saw and handled in dogs, pigs, serpents, frogs, and fishes, and even in slugs, oysters, lobsters, and insects, in the transparent *minima squilla*, “*quæ Anglice dicitur a shrimp,*” and lastly in the chick while still in the shell. In these investigations he used a *perspicillum* or simple lens. He particularly describes his observations and experiments on the ventricles, the auricles, the arteries, and the veins. He shows how the arrangement of the vessels in the *fœtus* supports his theory. He adduces facts observed in disease as well as in health to prove the rapidity of the circulation. He explains how the mechanism of the valves in the veins is adapted, not, as Fabricius believed, to moderate the flow of blood from the heart, but to favour its flow to the heart. He estimates the capacity of each ventricle, and reckons the rate at which the whole mass of blood passes through it. He elaborately and clearly demonstrates the effect of obstruction of the blood-stream in arteries or in veins, by the forceps in the case of a snake, by a ligature on the arm of a man, and illustrates his argument by figures. He then sums up his conclusion thus:—“*Circulari quodam motu, in circuitu, agitari in animalibus sanguinem, et esse in perpetuo motu; et hanc esse actionem sive functionem cordis quam pulsu peragit; et omnino motus et pulsus cordis causam unam esse.*” Lastly, in the 15th, 16th, and 17th chapters, he adds certain confirmatory evidence, as the effect of position on the circulation, the absorption of animal poisons and of medicines applied externally, the muscular structure of the heart and the necessary working of its valves. The whole treatise, which occupies only 67 pages of large print in the quarto edition of 1766, is a model of accurate observation, patient accumulation of facts, ingenious experimentation, bold yet cautious hypothesis, and logical deduction.

In one point only was the demonstration of the circulation incomplete. Harvey could not discover the capillary channels by which the blood passes from the arteries to the veins. This gap in the circulation was supplied several years later by the great anatomist Malpighi, who in 1661 saw in the lungs of a frog, by the newly invented microscope, how the blood passes from the one set of vessels to the other. Harvey saw all that could be seen by the unaided eye in his observations on living animals; Malpighi, four years after Harvey’s death, by another observation on a living animal, completed the splendid chain of evidence. If this detracts from Harvey’s merit it leaves Servetus no merit at all. But in fact the existence of the channels first seen by Malpighi was as clearly pointed to by Harvey’s reasoning as the existence of Neptune by the calculations of Le Verrier and of Adams.

Harvey himself and all his contemporaries were well aware of the novelty and importance of his theory. He says in the admirable letter to Dr Argent, president of the College of Physicians, which follows the dedication of his treatise to Charles I., that he should not have ventured to publish “a book which alone asserts that the blood pursues its course and flows back again by a new path, contrary to the received doctrine taught so many ages by innumerable learned and illustrious men,” if he had not set forth his theory for more than nine years in his college lectures, gradually brought it to perfection, and convinced his colleagues by actual demonstrations of the truth of what he advanced. He anticipates opposition, and even obloquy or loss, from the novelty of his views. These anticipations however, the event proved to

have been groundless. If we are to credit Aubrey indeed, he found that after the publication of the *De Motu* "he fell mightily in his practice; 'twas believed by the vulgar that he was crackbrained, and all the physicians were against him." But the last assertion is demonstrably untrue; and if apothecaries and patients ever forsook him, they must soon have returned, for Harvey left a handsome fortune. By his own profession the book was received as it deserved. So novel a doctrine was not to be accepted without due inquiry, but his colleagues had heard his lectures and seen his demonstrations for years; they were already convinced of the truth of his theory, urged its publication, continued him in his lectureship, and paid him every honour in their power. Abroad the book was widely read and much canvassed. Few accepted the new theory; but no one dreamt of claiming the honour of it for himself, nor for several years did any one pretend that it could be found in the works of previous authors. The first attack on it was a feeble tract by one Primerose, a pupil of Riolanus (*Exerc. et Animadv. in Libr. Harvey de Motu Cord. et Sang.*, 1630). Five years later Parisanus, an Italian physician, published his *Lapis Lydius de Motu Cord. et Sang.* (Venice, 1635), a still more bulky and futile performance. Primerose's attacks were "imbellia pleraque" and "sine ictu;" that of Parisanus "in quamplurimum turpius," according to the contemporary judgment of Vessling. Their dullness has protected them from further censure. Caspar Hoffmann, professor at Nuremberg, while admitting the truth of the lesser circulation in the full Harveyan sense, denied the rest of the new doctrine. To him the English anatomist replied in a short letter, still extant, with great consideration yet with modest dignity, beseeching him to convince himself by actual inspection of the truth of the facts in question. He concludes—"I accept your censure in the candid and friendly spirit in which you say you wrote it; do you also the same to me, now that I have answered you in the same spirit." This letter is dated May 1636, and in that year Harvey passed through Nuremberg with the earl of Arundel, and visited Hoffmann. But he failed to convince him; "nec tamen valuit Harveyi vel coram," writes Schlegel, who, however, afterwards succeeded in persuading the obstinate old Galenist to soften his opposition to the new doctrine, and thinks that his complete conversion might have been effected if he had but lived a little longer—"nec dubito quin concessisset tandem in nostra castra." While in Italy the following year Harvey visited his old university of Padua, and demonstrated his views to Professor Vessling. A few months later this excellent anatomist wrote him a courteous and sensible letter, with certain objections to the new theory. The answer to this has not been preserved, but it convinced his candid opponent, who admitted the truth of the circulation in a second letter (both were published in 1640), and afterwards told a friend, "Harveium nostrum si audis, agnosces colestem sanguinis et spiritus ingressum ex arteriis per venas in dextrum cordis sinum." Meanwhile a greater convert, Descartes, in his *Discours sur la Méthode* (1637) had announced his adhesion to the new doctrine, and refers to "the English physician to whom belongs the honour of having first shown that the course of the blood in the body is nothing less than a kind of perpetual movement in a circle." Walaeus of Leyden, Regius of Utrecht, and Schlegel of Hamburg successively adopted the new physiology. Of these professors, Regius was mauled by the pertinacious Primerose and mauled him in return (*Spongia qua elumitur sordes quæ Jac. Primrosius*, &c., and *Antidotum adv. Spongiam venenatam Henr. Regii*). Descartes afterwards repeated Harvey's vivisections, and, more convinced than ever, demolished an unlucky Professor Plempius of Louvain, who had written on the other side. Dr George Ent also published an *Apologia pro Circulatione Sanguinis* in answer to Parisanus.

At last Riolan ventured to publish his *Enchiridium Anatomicum* (1648), in which he attacks Harvey's theory, and proposes one of his own. Riolan had accompanied the queen dowager of France (Maria de' Medici) on a visit to her daughter at Whitehall, and had there met Harvey and discussed his theory. He was, in the opinion of the judicious Haller, "vir asper et in numero suosque coevos inimitis ac nemini parcens, nimis avidus suarum laudum præco, et se ipso fatente anatomicorum princeps." Harvey replied to the *Enchiridium* with perfectly courteous language and perfectly conclusive arguments, in two letters *De Circulatione Sanguinis*, which were published at Cambridge in 1649, and are still well worth reading. He speaks here of the "circuitus sanguinis a me inventus." Riolan was unconvinced, but lived to see another professor of anatomy appointed in his own university who taught Harvey's doctrines. Even in Italy, Trullius, professor of anatomy at Rome, expounded the new doctrine in 1651. But the most illustrious converts were Pecquet of Dieppe, the discoverer of the thoracic duct, and of the true course of the lacteal vessels, and Thomas Bartholinus of Copenhagen, in his *Anatome ex omnium Veterum Recentiorumque Observationibus, imprimis Institutionibus bovis mei parædis Caspari Bartholini, ad Circulationem Harveyanam et vasa lymphatica renovata* (Leyden, 1651). At last Plempius also retraced all his objections; for, as he candidly stated, "having opened the bodies of a few living dogs, I find that all Harvey's state-

ments are perfectly true." Hobbes of Malmesbury could thus say in the preface to his *Elementa Philosophiæ* that his friend Harvey, "solus quod sciam, doctrinam novam superata invidia vivens stabilivit."

It has been made a reproach to Harvey that he failed to appreciate the importance of the discoveries of the lacteal and lymphatic vessels by Aselli, Pecquet, and Bartholinus. In three letters on the subject, one to Dr Morrison of Paris (1652) and two to Dr Horst of Darmstadt (1655), a correspondent of Bartholinus's, he discusses these observations, and shows himself unconvinced of their accuracy. He writes, however, with great moderation and reasonableness, and excuses himself from investigating the subject further on the score of the infirmities of age; he was then above seventy-four. The following quotation shows the spirit of these letters:—"Laudo equidem summopere Pecqueti aliorumque in indaganda veritate industriam singularem, nec dubito quin multa adhuc in Democriti puteo abscondita sint, a venturi sæculi indefatigabili diligentia expromenda." Bartholin, though reasonably disappointed in not having Harvey's concurrence, speaks of him with the utmost respect, and generously says that the glory of discovering the movements of the heart and of the blood was enough for one man.

Harvey's Work on Generation.—We have seen how Dr Ent persuaded his friend to publish this book in 1651. It is between five and six times as long as the *Exerc. de Motu Cord. et Sang.*, and is followed by excursus *De Partu, De Uteri Membranis, De Conceptione*; but, though the fruit of as patient and extensive observations, its value is far inferior. The subject was far more abstruse, and in fact inaccessible to proper investigation without the aid of the microscope. And the field was almost untrodden since the days of Aristotle. Fabricius, Harvey's master, in his work *De Formatione Ovi et Pulli* (1621), had alone preceded him in modern times. Moreover, the seventy-two chapters which form the book lack the coordination so conspicuous in the earlier treatise, and some of them seem almost like detached chapters of a system which was never completed or finally revised.

Aristotle had believed that the male parent furnished the body of the future embryo, while the female only nourished and formed the seed; this is in fact the theory on which, in the *Eumenides* of Æschylus, Apollo obtains the acquittal of Orestes. Galen taught almost as erroneously that each parent contributes seeds, the union of which produced the young animal. Harvey, after speaking with due honour of Aristotle and Fabricius, begins rightly "ab ovo"; for, as he remarks, "eggs cost little and are always and everywhere to be had," and moreover "almost all animals, even those which bring forth their young alive, and man himself, are produced from eggs" ("omnia omnino animalia, etiam vivipara, atque hominem adeo ipsum, ex ovo progigni"). This dictum, usually quoted as "omne vivum ex ovo," would alone stamp this work as worthy of the discoverer of the circulation of the blood, but it was a prevision of genius, and was not proved to be a fact until Von Baer discovered the mammalian ovum in 1827. Harvey proceeds with a careful anatomical description of the ovary and oviduct of the hen, describes the new-laid egg, and then gives an account of the appearance seen on the successive days of incubation, from the 1st to the 6th, the 10th, and the 14th, and lastly describes the process of hatching. He then comments upon and corrects the opinions of Aristotle and Fabricius, declares against spontaneous generation (though in one passage he seems to admit the current doctrine of production of worms by putrefaction as an exception), proves that there is no *semen femininum*, that the chalazæ of the hen's egg are not the *semen galli*, and that both parents contribute to the formation of the egg. He describes accurately the first appearance of the ovarian ova as mere specks, their assumption of yolk, and afterwards of albumen. In chapter xlv. he describes two methods of production of the embryo from the ovum: one is *metamorphosis*, or the direct transformation of pre-existing material, as a worm from an egg, or a butterfly from an *aretia* (chrysalis); the other is *genesis*, or development with addition of parts, the true generation observed in all higher animals. Chapters xlvi.-l. are devoted to the abstruse question of the efficient cause of generation, which, after much discussion of the opinions of Aristotle and of Sennertius, Harvey refers to the action of both parents as the efficient instruments of the first great cause.¹ He then goes on to describe the

¹ So in *Exerc.* liv.: "Superior itaque et divinior opifex, quam est homo, videtur hominem fabricare et conservare, et nobilior artifex, quam gallus, pullum ex ovo producere. Nempe agnosceamus Deum, creatorem omnium atque omnipotentem, in cunctis animalium fabricis ubique præceterum esse, et in operibus suis, quasi digito monstrari: culus in procreatione pulli instrumenta sunt gallus et gallina. . . . Nec eulquam sano hæc attributa conveniant nisi omnipotentis verum Principis, quocunque demum nomine idipsum appellare libuerit: sive Mentem divinam cum Aristotele, sive cum Platone Animam Mundi, aut cum illis Naturam naturantem, vel cum ethiælis Saturnum aut Jovem; vel potius (ut nos decet) Creatorem ac Patrem omnium que in cælis et terris, a qua animalium cujusque origines dependent, ejusque nihil sive effato sunt et generantur omnia."

order in which the several parts appear in the chick. He states that the *punctum saliens* or fetal heart is the first organ to be seen, and explains that the nutrition of the chick is not only effected by yolk conveyed directly into the midgut, as Aristotle taught, but also by absorption from yolk and white by the umbilical (omphalomesenteric) veins; on the fourth day of incubation appear two masses (which he oddly names *vermiculus*), one of which develops into three vesicles, to form the cerebrum, cerebellum, and eyes, the other into the breastbone and thorax; on the sixth or seventh day come the viscera, and lastly, the feathers and other external parts. Harvey points out how nearly this order of development in the chick agrees with what he had observed in mammalian and particularly in human embryos. He notes the bifid apex of the fetal heart in man and the equal thickness of the ventricles, the soft cartilages which represent the future bones, the large amount of liquor amnii and absence of placenta which characterize the fœtus in the third month; in the fourth the position of the testes in the abdomen, and the uterus with its Fallopian tubes resembling the uterus bicornis of the sheep; the large thymus; the cæcum, small as in the adult, not forming a second stomach as in the pig, the horse, and the hare; the lobulated kidneys, like those of the seal ("*vitulo*," sc. *marino*) and porpoise, and the large suprarenal veins, not much smaller than those of the kidneys (li.-lvi.). He failed, however, to trace the connexion of the urachus with the bladder. In the following chapters (lxiii.-lxxii.) he describes the process of generation in the fallow deer or the roe. After again insisting that all animals arise from ova, that a "conception" is an internal egg and an egg an extruded conception, he goes on to describe the uterus of the doe, the process of impregnation, and the subsequent development of the fœtus and its membranes, the *punctum saliens*, the cotyledons of the placenta, and the "uterine milk," to which Professor Turner has lately recalled attention. The treatise concludes with detached notes on the placenta, parturition, and allied subjects.

Harvey's other Writings and Medical Practice.—The remaining writings of Harvey which are extant are unimportant. A complete list of them will be found below, together with the titles of those which we know to be lost. Of these the most important were probably that on respiration, and the records of post-mortem examinations. From the following passage (*De Partu*, p. 550) it seems that he had a notion of respiration being connected rather with the production of animal heat than, as then generally supposed, with the cooling of the blood. "Hæc qui diligenter perpenderit, naturamque aeris diligenter introspererit, facile opinor fatebitur eundem nec refrigerationis gratia nec in pabulum animalibus concedi. Hæc autem obiter duntaxat de respiratione diximus, proprio loco de eadem forsitan copiosius disceptaturi."

Of Harvey as a practising physician we know very little. Aubrey tells us that "he paid his visits on horseback with a footcloth, his man following on foot, as the fashion then was." He adds—"Though all of his profession would allow him to be an excellent anatomist, I never heard any that admired his therapeutic way. I knew several practitioners that would not have given threepence for one of his bills" (the apothecaries used to collect physicians' prescriptions and sell or publish them to their own profit), "and that a man could hardly tell by his bill what he did aim at." However this may have been,—and rational therapeutics was impossible when the foundation-stone of physiology had only just been laid,—we know that Harvey was an active practitioner, performing such important surgical operations as the removal of a breast, and he turned his obstetric experience to account in his book on generation. Some good practical precepts as to the conduct of labour are quoted by Willoughby, a contemporary. He also took notes of the anatomy of disease; these unfortunately perished with his other manuscripts. Otherwise we might regard him as a forerunner of Morgagni; for Harvey saw that pathology is but a branch of physiology, and like it must depend first on accurate anatomy. He speaks strongly to this purpose in his first epistle to Riolanus: "Sicut enim sanorum et boni habitus corporum dissectio plurimum ad philosophiam et rectam physiologiam facit, ita corporum morbosorum et cachecticorum inspectio potissimum ad patho-

logiam philosophicam." The only specimen we have of his observations in morbid anatomy is his account of the post-mortem examination made by order of the king on the body of the famous Thomas Parr, who died in 1635, at the reputed age of 152. Harvey insists on the value of physiological truths for their own sake, independently of their immediate utility; but he himself gives us an interesting example of the practical application of his theory of the circulation in the cure of a large tumour by tying the arteries which supplied it with blood (*De Generat. Exerc. xix.*).

The following is believed to be a complete list of all the known writings of Harvey, published and unpublished:—

Excercitatio Anatomica de Motu Cordis et Sanguinis, 4to, Frankfurt-on-the-Maine, 1628; *Excercitationes duæ Anatomice de Circulatione Sanguinis, ad Johannem Riolanum, filium, Parisiensem*, Cambridge, 1649; *Excercitationes de Generatione Animalium, quibus accedunt quædam de Partu, de Membranis ac Humoribus Uteri, et de Conceptione*, 4to, Lond., 1651; *Anatomia Thomæ Parr*, first published in the treatise of Dr John Betts, *De Ortu et Natura Sanguinis*, 8vo, Lond., 1669. Letters:—(1) to Caspar Hoffmann of Nuremberg, May 1636; (2) to Schlegel of Hamburg, April 1651; (3) three to Giovanni Nardi of Florence, July 1651, Dec. 1653, and Nov. 1655; (4) two to Dr Morrison of Paris, May 1652; (5) two to Dr Horst of Darmstadt, Feb. 1654-5 and July 1655; (6) to Dr Vlackvel of Haarlem, May 1657. His letters to Hoffmann and Schlegel are on the circulation; those to Morrison, Horst, and Vlackvel refer to the discovery of the lacteals; the two to Nardi are short letters of friendship. All these letters were published by Sir George Ent in his collected works (Leyden, 1687). Of two MS. letters, one on official business to the secretary Dorchester was printed by Dr Aveling, with a facsimile of the crabbed handwriting (*Memorials of Harvey*, 1875), and the other, about a patient, appears in Dr Willis's *Life of Harvey*, 1878. *Prælectiones anatomie universalis per me Gul. Harveium medicum Londinensem, anat. et chir. professorem, an. dom. 1616, ætat. 37.*—MS. notes of his Lunslean lectures in Latin,—are in the British Museum library; they are almost illegible, but were partly deciphered and a photograph of one of the pages taken by Dr Sieveking; for an account of them see his *Harveian Lecture* for 1877. A second MS. has been discovered in the British Museum, entitled *Gulielmus Harveius de Musculis, Motu Locali, &c.*, and an account of it was published by Dr George Paget (*Notice of an unpublished MS. of Harvey*, Lond., 1850). The following treatises, or notes towards them, were lost either in the pillaging of Harvey's house, or perhaps in the fire of London, which destroyed the old College of Physicians:—*A Treatise on Respiration*, promised, and probably at least in part completed (pp. 82, 550, ed. 1766); *Observationes de usu Licnis*; *Observationes de motu locali*, perhaps identical with the above-mentioned manuscript; *Tractatum physiologicum*; *Anatomia medicalis* (apparently notes of morbid anatomy); *De Generatione Insectorum*. The fine 4to edition of Harvey's *Works*, published by the Royal College of Physicians in 1766, was superintended by Dr Mark Akenside; it contains the two treatises, the account of the post-mortem examination of old Parr, and the six letters enumerated above. A translation of this volume by Dr Willis, with Harvey's will, was published by the Sydenham Society, 8vo, Lond., 1849.

The following are the principal biographies of Harvey:—in Aubrey's *Letters of Eminent Persons*, &c. (vol. ii., Lond., 1813), first published in 1685, the only contemporary account; in Bayle's *Dictionnaire Historique et Critique*, 1698 and 1720 (Eng. ed., 1738); in the *Biographia Britannica*, and in Aitken's *Biographical Memoirs*; the Latin Life by Dr Lawrence, prefixed to the college edition of Harvey's *Works* in 1766; memoir in *Lives of British Physicians*, Lond., 1830; a Life by Dr Robert Willis, founded on that by Lawrence, and prefixed to his English edition of Harvey in 1847; the much enlarged Life by the same author, published in 1878; the biography by Dr Monk in the *Roll of the College of Physicians*, 2d ed., vol. i., 1879.

The literature which has arisen on the great discovery of Harvey, on his methods and his merits, would fill a library. The most important contemporary writings have been mentioned above. The following list gives some of the most remarkable in modern times:—the article in Bayle's dictionary quoted above; *Anatomical Lectures*, by Wm. Hunter, M.D., 1784; Sprengel, *Geschichte der Arzneikunde*, Halle, 1800, vol. iv.; Flourens, *Histoire de la Circulation*, 1854; Lewes, *Physiology of Common Life*, 1859, vol. i. pp. 291-345; Ceradini, *La Scoperta della Circolazione del Sangue*, Milan, 1876; Tollin, *Die Entdeckung des Blutkreislaufs durch Michael Servet*, Jena, 1876; Kirchner, *Die Entdeckung des Blutkreislaufs*, Berlin, 1878; Willis, in his Life of Harvey; Wharton Jones, "Lecture on the Circulation of the Blood," *Lancet* for Oct. 25 and Nov. 1, 1879; and the *Harveian Orations*, especially those by Dr Sieveking, Dr Guy, and Prof. Rolleston. (F. H. P.-S.)

HARWICH, a municipal and parliamentary borough and seaport town of Essex, England, is situated on the extremity of a small peninsula projecting into the estuary of the Stour and Orwell, 70 miles N.E. of London by the Great Eastern Railway. It occupies an elevated situation, and a good view is obtained from Beacon Hill at the southern end of the esplanade. The town is somewhat irregularly built, but the streets though narrow are well paved. It is defended by a redoubt mounted with heavy guns and by three martello towers. The only public building of importance is the church of St Nicholas, an edifice of white brick in the Perpendicular style, with stone buttresses and steeple, erected in 1821 at a cost of £20,000. The harbour is one of the best on the east coast of England, and in stormy weather is largely taken advantage of for shelter. Its entrance is, however, encumbered with rocks, and is dangerous without a pilot. The rapid accumulation of shingle threatened some years ago to block up the principal entrance, but this has been prevented by the construction of two breakwaters, having a length respectively of 1350 and 1000 feet. The shipping trade of the port was much injured by the removal, after the introduction of steamships, of the Hamburg and other packets from the station; but since the construction of the Great Eastern Railway steam packets have plied regularly between Harwich and Antwerp and Rotterdam. In 1878-1198 British ships entered the port with a tonnage of 298,227, and 35 foreign ships with a tonnage of 10,921. The number of British ships that cleared was 1233, with a tonnage of 296,095, and of foreign ships 28, with a tonnage of 8544. The principal imports are grain, timber, and tobacco, and the principal exports cement and fish. Shipbuilding has declined since the discontinuance of the Government dockyards. The prosperity of the town depends now largely on its shrimp and lobster fisheries, but there are also Roman cement works, breweries, and manufactories for artificial manure and for sails and tackle. It is much frequented for sea-bathing, and its suburb of Dovercourt possesses a chalybeate spring, the spa-house of which contains a library and museum. Harwich in all probability occupies the site of a Roman station. In 855 a great naval battle took place opposite the town between the Danes and the fleet of King Alfred, and in 1666 another took place between the Dutch and the English. Harwich was created a parliamentary borough by King Edward II. in 1318 with the privilege of returning two members, but since the Reform Act of 1867 it has returned only one. The population of the municipal and parliamentary borough in 1871 was 6079.

HARZ MOUNTAINS, THE (also spelt HARTZ, the German *Harzgebirge*, and the ancient *Silva Hercynia*), the most northerly mountain-system of Germany, situated between the rivers Weser and Elbe, occupy an area of about 786 square miles, of which 457 belong to Prussia, 286 to Brunswick, and 43 to Anhalt. Their greatest length extends in a S.E. and N.W. direction for about 56 miles, and their maximum breadth is about 20 miles. The group is made up of an irregular series of terraced plateaus, rising here and there into rounded summits, and intersected in various directions by narrow, deep valleys. The N.W. and higher part of the mass is called the Ober or Upper Harz; the S.E. and more extensive part, the Unter or Lower Harz; while the N.W. and S.W. slopes of the Upper Harz form the Vorharz. The Brocken group, which divides the Upper and Lower Harz, is generally regarded as a part of the former. The prevalent upper geological formation of the whole district is greywacke and clay-slate, through which the granite here and there protrudes, as in the case of the Brocken. The highest summits of the Upper Harz are the Brocken (3743 feet), the Heinrichshöhe (3402 feet), the Greater and Less Königsberg (3376 feet and

3369 feet), and the Wornberg (3182 feet); the Lower Harz, the Anersberg (1870 feet), and the Victorshöhe (1762 feet). The towns in the district, though not large, are tolerably numerous. The principal are—in the Upper Harz, Goslar, Klausthal, Zellerfeld, Andreasberg, Altenau, Lautenthal, Wildemann, Grund, Harzburg, Ilseburg, and Wernigerode; and in the Lower Harz, Harzgerode, Elbingerode, Rübeland, Quedlinburg, Ballenstedt, Gernrode, Suderode, Blankenburg, Thale, and Stolberg.

The chief industry is mining, which has been carried on since the middle of the 10th century. The Harz is second only to the Erzgebirge among the mountains of Germany in mineral wealth. The most important mineral is a peculiarly rich argentiferous lead, but gold in small quantities, copper, iron, sulphur, alum, and arsenic are also found. Marble, granite, and gypsum are worked; and large quantities of vitriol are manufactured. The vast forests that cover the mountain-slopes supply the materials for a very considerable trade in timber. Much wood is exported for building and other purposes, while in the Harz itself no other fuel is used, whether for smelting the ores, which is done at the mines, or for domestic use. Employment is thus given to a large number of charcoal burners. The saw-dust of the numerous wood-factories is collected for use in the manufacture of paper. Turf-cutting, coarse lace-making, and the breeding of canaries and native song-birds also occupy many of the people. Agriculture is carried on chiefly on the plateaus of the Lower Harz; but there is excellent pasturage both in the north and in the south. In the Lower Harz, as in Switzerland, the cows, which carry bells harmoniously tuned, are driven up into the heights in early summer, returning to the sheltered regions in late autumn.

The Harz being the first obstacle to oppose the moist, cold winds from the North Sea, the northern summits are destitute of trees, but the lower slopes of the Upper Harz are heavily wooded with pines and firs. Between the forests of these stretch numerous peat-mosses, which contain in their spongy reservoirs the sources of many small streams. On the Brocken are found one or two arctic and several alpine plants. In the Lower Harz the forests contain a great variety of timber. The oak, elm, and birch are common, while the beech especially attains an unusual size and beauty. The walnut-tree grows in the eastern districts.

The last bear was killed in the Harz in 1705, and the last lynx in 1817, and since that time the wolf too has become extinct; but deer, foxes, wild cats, and badgers are still to be found in the forests.

The streams are very numerous, but are all small. While they are rendered extensively useful, by various skilful artifices, in working the mines underground, at other parts of their course they present the most picturesque scenery in all the picturesque Harz. Perhaps the finest valley is the rocky Bodethal, with the Ross-Trappe, the Hexentanzplatz, the Baumansshöhle, and the Bielsshöhle.

The inhabitants, about 70,000 in number, are descended from various stocks. The Upper and Lower Saxon, the Thuringian, and the Frankish races have all contributed to form the present people, and their respective influences are still to be traced in the varieties of dialect. The boundary line between High and Low German passes through the Harz.

The Harz is now one of the most frequented tourist resorts of Germany. It is traversed by excellent roads in all directions, and is completely girt by railways from the principal towns of the empire. The chief point of interest is undoubtedly the Brocken or Blocksberg, famous as the scene of the "Walpurgisnacht" in Goethe's *Faust*, as well as for the atmospheric phenomena of which the "spectre of the Brocken" (see HALO) is the best known. The Harz was the last stronghold of paganism in Germany, and to that fact are due the weird legends, in which no district is

richer, and the wild and fanciful names that are given by the people to the peculiar objects and appearances of nature.

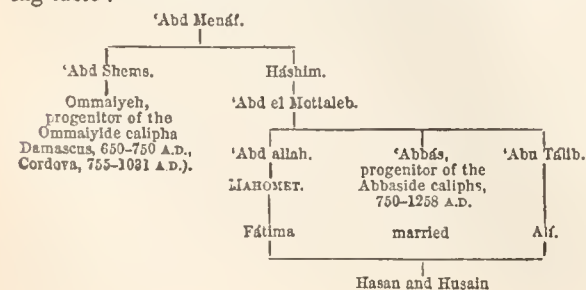

Literature.—A very full list of works on the Harz, especially on the Brocken, will be found appended to the pamphlet *Zur Geschichte der Brockenreisen*, 4th ed., Aschersleben and Leipzig, 1875. See also Holzmann, *Herzynisches Archiv*, Halle, 1803; Honemann, *Die Alterthümer des Harzes*, Klausthal, 1827; Zimmerman, *Harzgebirge*, Darmstadt, 1834; Hoffmann, *Burgen und Burgfesten des Harzes*, Quedlinburg, 1836; Hausmann, *Ueber die Bildung des Harzgebirges*, Göttingen, 1842; *Brockenstammbuch*, 1850; Brederlow, *Der Harz, zur Belehrung und Unterhaltung für Harzreisende*, Brunswick, 1851; Lachmann, *Nivellement des Harzgebirges*, Brunswick, 1851; Spicker, *Der Harz, seine Ruinen und Sagen*, Berlin, 1852 and 1856; Ey, *Harzbuch*, Goslar, 1855; Pröhle, *Harzsagen*, 1854; *Harzbilder*, 1856; *Harz und Kyffhäuser in Gedichten, Schilderungen, &c.*, 1870, and *Der Harz*, 1878; *Wegweiser im Harz und dessen Umgegend*, Berlin, 1857; Nauenburg, *Der Lustwanderer im Harz*, Eisleben, 1857; Mrs Burton, *Our Summer in the Harz Forest*, Edinburgh, 1865; Groddeck, *Abriss der Geognosie des Harzes*, Klausthal, 1871; Hampe, *Flora Herzynia*, Halle, 1873; Blackburn, *The Harz Mountains, a Tour*, London, 1873; Buch (*Gesammelte Schriften*), "Ueber den Harz," 1877; Rev. J. S. Hill and J. W. Tanley, in *Colliery Guardian*, vol. xxx.; Heine, *Harzreise*. Among the Handbooks may be noted those of Schweizer, Werner, Gottschalk, Meyer, Muller, Prediger, and Grieben.

HARZBURG, or **NEUSTADT-HARZBURG**, the chief town of an office in the Brunswick circle of Wolfenbüttel, Prussia, is situated 727 feet above sea-level on the right bank of the Radau, a tributary of the Ocker, and at the terminus of the Brunswick-Harzburg Railway, 5 miles E.S.E. from Goslar and 18 miles S. from Wolfenbüttel. The opening of the railway has made the Harzburg route a principal one for persons visiting the Harz, and the town is also much frequented as a summer residence. It possesses a salt-water bath and also a hydropathic establishment. A mile and a half south from the town lies the Burgberg, 1500 feet above sea-level, on whose summit, according to tradition, there was at one time an altar to the heathen idol Krodo, still to be seen in the Ulrich chapel at Goslar. There are now on the summit of the hill a hotel, the remains of an old castle, and a monument erected in 1875 to the honour of Prince Bismarck, with an inscription taken from one of his speeches against the Ultramontane claims of Rome—"Nach Canossa gehen wir nicht." The population of Harzburg in 1875, including the villages of Bündheim, Schulenrode, and Schlewecke, was 4271.

The castle was built by the emperor Henry IV. between 1065 and 1069, but was laid in ruins by the Saxons about 1050. By Frederick I. it was granted to Henry the Lion, who caused it to be rebuilt with great splendour about 1130. It was a frequent residence of Otto IV., who died at it, and by his will granted it to the counts of Woldenberg. After being frequently besieged and taken, it finally, after the battle of Mühlberg in 1546, passed to the house of Brunswick. It ceased to be of importance as a fortress after the Thirty Years' War, and gradually fell into ruins.

See Dellius, *Untersuchungen über die Geschichte der Harzburg*, Halberstadt, 1825; Dommes, *Harzburg und seine Umgebung*, Goslar, 1862; Holmstein, *Die Harzburg nach Sage und Geschichte*, Brunswick, 1878.

HASAN and **HUSEIN**, the sons of 'Alī ibn Abu Tālib, cousin and son-in-law of Mahomet, and heroes of the passion play performed annually throughout India and Persia by Shiah Mahometans in the month of Moharram. Their relationship to the prophet is important to the understanding of their history, and may be seen from the following table:—

The office of guardian of the kaabeh or temple of Mecca, and chief of the tribe of Koreish, which was vested in 'Abd Menāf, would have descended to 'Abd Shems, his eldest son, had it not been given to Hāshim, the second, in reward for some military successes, and this circumstance caused a bitter enmity between the two families. When Mahomet died, 'Alī claimed the right to the office of caliph (*khalifah*, "vicegerent" or "successor"), but found formidable rivals in Abu Bekr, the father of 'Ayesha the prophet's favourite wife, 'Omar, another of his fathers-in-law, and 'Othmān, the only member of the rival house of Ommāiyeh who had joined the Muslim ranks. 'Ayesha, whom 'Alī had mortally offended by listening to a charge of incontinence which had been made against her, made common cause with the Ommāiyides, and strenuously opposed 'Alī's accession. A compromise was effected by the election of Abu Bekr; on his death 'Omar was made caliph, and when he in turn died, 'Othmān was elected, as 'Alī refused to subscribe to the conditions imposed upon him that he should govern in accordance with the "traditions" as well as the Korān. These "traditions" are the whole body of ceremonial laws and customs by which the imperfect code of the Korān was supplemented; they are derived from ancient Arab and even Jewish usage, although to give them a proper sanction and force they have been attributed to Mahomet himself, who is supposed to have enunciated them at different times as separate *ahādīth* (singular, *hadīth*); and the tracing of them through the various authorities to the prophet himself is still a most important branch of Muslim theology.

The "traditions" are spoken of collectively as the *Sunneh*, whence the name Sunnī, given to that sect of Mahometans who follow them, and it was to this that 'Alī refused to subscribe. 'Othmān on his accession displayed an unblushing partisanship for his own, the Ommāiyide, family, and appointed Mo'āwiyeh, a bitter enemy of the Hāshimī family, governor of Syria. 'Othmān was assassinated in 655 A.D., and 'Alī was then unconditionally elected caliph. He immediately recalled Mo'āwiyeh, who refused to obey, and, supported by the influence of the implacable 'Ayesha, claimed the caliphate for himself. A severe struggle between the two parties ensued, and 'Alī was at first successful, but was at length compelled by intrigue to submit his claims to arbitration, instead of following up his military advantages. A number of his followers, about 12,000, taking umbrage at this, deserted him, thus originating the sect of Khārejīyeh or "Separatists," who reject the lawful government established by public consent. A conspiracy of three of these deserters resulted in the murder of 'Alī, who was slain at the door of a mosque in Kūfa, and buried at a spot about 5 miles from that town. A magnificent mausoleum was afterwards erected over his tomb, which became later on the site of the town Meshed 'Alī, "Alī's shrine," one of the great places of resort for Shiah pilgrims. On Alī's death his eldest son Hasan was elected caliph, but resigned the office in favour of Mo'āwiyeh on condition that he should resume it at the latter's death. Mo'āwiyeh, however, who wished his own son Yezīd to succeed him, caused Hasan to be foully murdered by his own wife eight years later. Yezīd succeeded his father, on the latter's death, without opposition or election, and the Ommāiyide dynasty became thus firmly established on the throne. The partisans of 'Alī's family were, however, far from content, and Husein, 'Alī's surviving son, was secretly invited to Kūfa to place himself at the head of the party, and revolt against Yezīd. Prompt measures were taken by the caliph, who had obtained timely warning of the movement. 'Obeidallah, a vigorous officer, was appointed governor of Kūfa, seized upon Husein's envoy, Muslim, and one Hāni in whose house he had been concealed, and when the populace assembled and clamoured for their release he caused them to be beheaded and their

heads to be cast down among the crowd. Husein was intercepted on the borders of Babylonia by Harro, with a company of horse, who told him he had orders to bring him alone to Kúfa, but allowed him to proceed by what route he chose without losing sight of him. A horseman met them on the road with secret orders from 'Obeidallah to lead Husein into an open and undefended place, and halt until 'Amer, the commander of the Syrian army, arrived with his forces. This happened the next day, and Husein and his small escort were surrounded by 4000 horse, and slaughtered, after a stubborn resistance, on the plain of Kerbelá by the banks of the Euphrates, under peculiarly tragic circumstances, his little son Abdallah, and his nephew, a beautiful child, both being murdered in his arms. This took place on the 10th of Moharram 61 A.H. (680 A.D.), and is commemorated during that month by the Shiáhs in India and Persia, a long miracle play performed, the scenes of which are carried on from day to day, and culminate in carrying out the *tabút* or coffins of the martyrs to an open place, generally the cemetery, or in sea-side places to the sea-shore.

The cause of 'Alí and his family was warmly expoused by the Persians, who had been forced to embrace Islám, but who regarded the Sunneh or Semitic law with especial repugnance. The party were known as Shiáhs, "Sectarians;" and as the quarrel between them and the Sunnis thus perpetuates the old enmity between Jew and Gentile, between the Semitic and Aryan races, it has produced an irreparable breach in Islám.

The passion play of *Hasan and Husein* has been published in English by Sir Lewis Pelly (London, 1879, 2 vols. 8vo) from the dictation of native teachers and performers of the drama. (E. H. P.)

HASBEYA, or HASBEIYA, a town of the Druses, about 36 miles west of Damascus, is situated at the foot of Mount Hermon in Syria, overlooking a deep amphitheatre, from which a brook flows to the Hasbáni. Both sides of the valley are planted in terraces with olives, vines, and other fruit trees. The grapes are either dried, or made into a kind of syrup. About four-fifths of the inhabitants are Christians, and in 1846 an American Protestant mission was established in the town. This little community suffered much persecution at first from the Greek Church, and afterwards from the Druses; by whom in 1860 nearly 1000 Christians were massacred, while others escaped to Tyre or Sidon. The castle in Hasbeya was held by the crusaders under Count Oran; but in 1171 the Druse emirs of the great Shehaab family (see DRUSES) recaptured it. In 1205 this family was confirmed in the lordship of the town and district, which they held till the Turkish authorities took possession of the castle in the present century. Near Hasbeya are bitumen pits let by Government; and to the north, at the source of the Hasbáni, the ground is volcanic. Some travellers have identified Hasbeya with the Biblical Baal-Gad, or Baal-Hermon,—a supposition rendered the more likely by the ruins of several temples near the town. Population about 5000.

HASDRUBAL. Of the bearers of this very common Carthaginian name the most famous are the following:—

1. One of the leaders of the popular party at the close of the First Punic War. He was conspicuous for his dexterous management in politics and his conciliatory manners. He married the daughter of Hamilcar Barca; and his skilful and cordial co-operation was of enormous consequence to Hamilcar during his Spanish wars. He went to Spain with his father-in-law, but soon returned to Carthage, where his talents were specially needed to conduct the party at home. He was, however, in Spain when Hamilcar fell (229); and was soon formally appointed by the home Government to the command which he had at once assumed. Devoting himself most successfully to the task

of consolidating the Carthaginian power in Spain, he founded New Carthage as the Spanish capital, and married the daughter of a Spanish chief. His kindly and generous manner attached the natives to him, and brought many over to the Carthaginian alliance. In 221 he fell by the hand of an assassin. The account given of him by Polybius is much more favourable and far more trustworthy than that of the Roman author Fabius whom he refers to.

2. The second son of the great Hamilcar. He was left by Hannibal as commander in Spain (219 B.C.), where he had to contend with the two Scipios, Cneius and Publius. Three years were spent in desultory warfare, in which the Romans were generally successful. After the battle of Canná, Hasdrubal was ordered to march into Italy, while Himilco was sent from Carthage with a fresh army to supply his place. But a decisive battle on the Ebro, in which he was totally defeated, checked his northward march. It is hardly possible to exaggerate the importance of this battle. Had a fresh Carthaginian army joined Hannibal in Italy for the campaign of 215 or 214, the danger to Rome would have been infinitely increased. Several years now passed, marked by the Roman historians with fresh Roman victories; and it is certain that the struggle continued doubtful till 212, when both the Scipios were defeated and slain. In spite of this great success, Hasdrubal was not at the moment able to begin the march on Italy. The Romans were skilfully rallied by Lucius Marcus, and in 211 a fresh army under the prætor Nero landed in Spain. At the same time there seems to have been no co-operation among the Carthaginian generals; and when the younger Scipio landed in Spain (210) he found their armies widely separated. Taking advantage of this, Scipio by a sudden attack (209) captured New Carthage, which contained vast military stores, all the Spanish hostages, and 10,000 captives. To achieve this brilliant success he had to leave the road northwards undefended; and although he rapidly returned and (according to the Roman accounts) defeated Hasdrubal at Bæcula in Andalusia, the Carthaginian general was able to make his way with a strong army to the Pyrenees, which he crossed in safety near the western extremity. The whole course of the Spanish wars, and especially the chronology of these later events, are very obscure. At all events Hasdrubal, after a very rapid and skilful march across the whole breadth of Gaul, appeared early in 207 in the north of Italy. When once he had succeeded in getting out of Spain, this brilliant march proved Hasdrubal worthy of his father and his brother; and long as it had taken to carry out his plan, we must remember that after the Romans perceived the necessity of keeping him back from Italy the difficulties in his way were enormous. On hearing of the passage of the Pyrenees, the Romans raised extraordinary levies, but before they had taken any steps to meet him, Hasdrubal was already in Cisalpine Gaul. Hannibal was still in Apulia, perhaps not expecting his brother so soon; Hasdrubal sent to meet him two Numidian horsemen with four Gauls, who almost at the end of their perilous journey fell into the hands of the consul Nero. In the meantime Hasdrubal had advanced into Umbria, where the plebeian consul Livius was examped near Sena. Nero, with 7000 men, left his own camp, and by a rapid march, which must be ranked among the most important events of the war, joined his colleague. The united army was much too strong for Hasdrubal. He tried to avoid a battle, but his guides failed him, and he was forced to fight on the south bank of the Metaurus. A long and bloody conflict resulted in the complete defeat of the Carthaginians, and Hasdrubal, after all was lost, fell sword in hand in the midst of the enemy. His head, which was thrown by Nero's soldiers into Hannibal's camp, first revealed to the latter his brother's defeat and the ruin of the Carthaginian cause.

HASLINGDEN, a market-town of Lancashire, England, is situated 7 miles S.E. of Blackburn, in a hilly district on the borders of the forest of Rossendale, and is supposed by some to derive its name from the hazel trees which at one time abounded in its neighbourhood. The town formerly stood on the slope of a hill, but the modern part, which is substantially built of stone, has been erected at its base. The parish church dedicated to St James was, with the exception of the tower, which dates from the time of Henry VIII., rebuilt in 1780, and the whole structure was restored in 1879. Handsome schools are attached, to which there is an endowment for ten poor boys, founded in 1749. The principal other buildings are the mechanics' institute, the town-hall, where the sessions and county court are held, and the public hall for assemblies. The woollen manufacture, formerly the staple of the town, has now been superseded by that of cotton, and there are also silk manufactures, iron-works, and size-works. In the vicinity there are collieries and quarries for stone, flags, and slate. The population of the town in 1861 was 6929, and 7698 in 1871, and that of the township was 10,109 and 12,000.

HASPE, a town of Prussia, province of Westphalia, government district of Arnsberg, and circle of Hagen, is situated in the valley of the Ennepe where the Hasper stream joins that river, and on the railway from Düsseldorf to Dortmund, 25 miles north-east of Düsseldorf. It has iron foundries, rolling mills, puddling furnaces, and manufactures of iron, steel, and brass wares, and of machines. Haspe was raised to the rank of a town in 1874. The population in 1875 was 7930.

HASSAN, a district of Mysore, India, lying between 12° 30' and 13° 22' N. lat. and between 75° 32' and 76° 58' E. long. It is bounded on the S.W. by the Madras district of South Kanara, and on the S. partly by the state of Coorg. The main portion of the district consists of the river basin of the Hemavati and its tributaries. It naturally divides into two portions, the Malnad or hill country, which includes some of the highest ranges of the Western Gháts, and the Maidán or plain country, sloping towards the south. The Hemavati, which flows into the Cauvery in the extreme south, is the great river of the district; its most important tributary is the Yagachi. The upper slopes of the Western Gháts are abundantly clothed with magnificent forests, and wild animals of all sorts abound. Among the mineral products are kaolin, felspar, and quartz. The soil of the valleys is a rich red alluvial loam.

The area extends to 3291 square miles. The census of 1871 returned the inhabitants at 669,961—329,097 males and 340,864 females—the Hindus numbering 650,877, Mahometans 14,460, Jains 1954, Christians 2670. Hassan town and Narsipur each contain more than 5000 inhabitants. The staple crops consist of *ragi*, rice, tobacco, sugar-cane, the cocoa-nut and arca-nut palms, plantain trees, and chillies. Coffee cultivation has been on the increase of late years. The first plantation was opened in 1843, and now there are 155 coffee estates owned by Europeans and 9500 native holdings. The statistics of irrigation show a total of 6905 tanks in the district and 215 miles of canals. The exports are large, consisting chiefly of food-grains and coffee. The imports are European piece-goods, hardware of all sorts, and spices. The largest weekly fair is held at Alur. A great annual religious gathering and fair, attended by about 10,000 persons, takes place every year at Melukot. The gross revenue amounted in 1873-74 to £126,908, and the police force (1874) numbered 470 men of all ranks, maintained at a cost of £3692. There were 243 schools in 1874 aided by Government, attended by 4379 pupils, and 147 unaided with 1657 pupils. The average mean temperature of the district is 76°, and the average rainfall at Hassan town during seven years was 36 inches. In the Gháts as much as 100 inches sometimes fall in the year. Malarious fever prevails in the Malnad during the early rains.

The real history of Hassan does not begin until the epoch of the Ballala dynasty, which lasted from the 10th till the 14th century. Their capital was at Dwarávati-pura, the ruins of which are still to be seen scattered round the village of Halebid in this district. The earlier kings professed the Jain faith, but the finest temples were

erected to Siva by the later monarchs of the line. While they were at the zenith of their power the whole of southern India acknowledged their sway. After the Mahometan invasion in the 14th century, the district of Hassan ceased to exist as the seat of a metropolis, and became a remote province known as Balam. Since 1832 the district, with the rest of Mysore, has been under direct British administration.

HASSAN. See ASSASSINS, vol. ii. p. 723.

HASSE, JOHANN ADOLPH (1699-1783), a musical composer, is a striking instance of the instability of fame. One of the most prolific and most celebrated composers of the 18th century, he is now all but forgotten, and his extant works rest quietly on the shelves of public libraries. He was born at Bergedorf near Hamburg, on March 25, 1699, and received his first musical education from his father. Being possessed of a fine tenor voice, he chose the theatrical career, and joined the operatic troupe conducted by Reinhard Keiser at Hamburg, the same Keiser in whose orchestra Handel had played the second violin some years before. Hasse's success led to an engagement at the court theatre of Brunswick, and it was there that, in 1723, he made his début as a composer with the opera *Antigonus*. The success of this first work induced the duke to send Hasse to Italy for the completion of his studies, and in 1724 he went to Naples and placed himself under the tuition of the celebrated Porpora, with whom, however, he seems to have disagreed both as a man and as an artist. On the other hand he gained the friendship of Alessandro Scarlatti, to whom he owed his first commission for a serenade for two voices, sung at a family celebration of a wealthy merchant by two of the greatest singers of Italy, Farinelli and Signora Tesi. This event established Hasse's fame; he soon became very popular by the name of "il caro Sassone," and his opera *Sesostrato*, written for and produced at the Royal Opera at Naples in 1726, made his name known all over Italy. At Venice, where he went in 1727, he and his works were received with equal favour. It was there that he became acquainted with the celebrated singer Faustina Bordoni, better known as Faustina Hasse, for she became the composer's wife in 1730. The artist-couple soon afterwards went to Dresden, in compliance with a brilliant offer made to them by the splendour-loving elector of Saxony, Augustus II. There Hasse remained for two years, after which he again journeyed to Italy, and also in 1733 to London, in which latter city he was tempted by the aristocratic clique inimical to Handel to become the rival and antagonist of that great master. But this he modestly and wisely declined, remaining in London only long enough to superintend the rehearsals for his opera *Artaserse*. All this while Faustina had remained at Dresden, the declared favourite of the public and unfortunately also of the elector, her husband, who remained attached to her, being allowed to see her only at long intervals. In 1739, after the death of Augustus II., Hasse settled permanently at Dresden till 1763, when he and his wife retired from court service with considerable pensions. But Hasse was still too young to rest on his laurels. He went with his family to Vienna, and added several operas to the great number of his works already in existence. His last work for the stage was the opera *Ruggiero*, written for the wedding of Archduke Ferdinand at Milan. On the same occasion a dramatic cantata by Mozart, then (1771) fourteen years old, was performed, and Hasse is said to have prophesied Mozart's future greatness much in the same manner as Mozart himself predicted that of Beethoven. By desire of his wife Hasse settled at her birthplace Venice, and there he died December 23, 1783. His compositions were innumerable, including as many as 120 operas, besides oratorios, cantatas, masses, and almost every variety of instrumental music. It would be needless to criticize or give the titles of these compositions, for most of them are,

as was said before, totally and not unjustly forgotten. Moreover, comparatively few of them have escaped destruction. During the siege of Dresden by the Prussians in 1760, most of his manuscripts, collected for a complete edition to be brought out at the expense of the elector, were burnt. Some of his works, amongst them an opera *Alcide al Bivio*, have been published, and the libraries of Vienna and Dresden possess the autographs of others. Hasse's instrumentation is certainly not above the low level attained by the average musicians of his time, and his *ensembles* do not present any features of interest. In dramatic fire also he was wanting, but he had a fund of gentle and genuine melody, and by this fact his enormous popularity during his life must be accounted for. The two airs which Farinelli had to repeat every day for ten years to the melancholy king of Spain, Philip V., were both from Hasse's works. Of Faustina Hasse, almost as celebrated as her husband, most that is necessary has been said above. It will be sufficient to add that she was born at Venice in 1700, sang at Vienna; London (under Handel, 1726), and Dresden, and was, according to the unanimous verdict of the critics (including Dr Burney), one of the greatest singers of a time rich in vocal artists. The year of her death is not exactly known. Most probably it shortly preceded that of her husband.

HASSELQUIST, FREDERICK (1722-1752), a Swedish traveller and naturalist, was born near Linköping in East Gothland, 3d January 1722. He lost his father at an early age, and his uncle, his sole remaining protector, in his thirteenth year, but succeeded by means of private teaching in supporting himself while continuing his education. In 1741 he entered the university of Upsala, where his taste for the study of nature was fostered and developed by Linnæus, and where in 1747 he obtained licence in medicine, and published a thesis entitled *De Viribus Plantarum*. On account of the frequently expressed regrets of Linnæus at the lack of information regarding the natural history of Palestine, Hasselquist resolved to undertake a journey to that country, and a sufficient subscription having been obtained to defray expenses, he, after making himself acquainted with the languages of the Levant, embarked for Smyrna, where he arrived November 26, 1749. He visited parts of Asia Minor, Egypt, Cyprus, and Palestine, and made large natural history collections, but his constitution, naturally weak, gave way under the fatigues and anxieties of travel, and he died at Smyrna, February 9, 1752, on his way homewards. His collections reached home in safety, and five years after his death the results of his wanderings were published by Linnæus under the title *Resa till Heliga Landet förättad från år 1749 till 1752*. The work is divided into two parts, the first consisting of the traveller's journal and letters, and the second of his remarks on the botany, zoology, and mineralogy of the countries through which he passed, with observations on the prevalent diseases and their cure, and the state of industry, commerce, and the arts. It was translated into French and German in 1762, and into English in 1766.

HASSELT, a town of Belgium, capital of the province of Limburg, is situated on the Demer and on the railway from Aix-la-Chapelle to Maestricht, 20 miles north-west of Liège. It possesses two churches, a hospital, a spacious town-hall, an athenæum, and a public library. Tobacco and madder are cultivated in the neighbourhood. The principal manufactures are linen, lace, brandy, and beer. At Hasselt the Dutch under the prince of Orange gained a victory over the Belgians under General Daine, 6th May 1831. The population in 1876 was 11,361.

HASSENPLUG, HANS DANIEL LUDWIG FRIEDRICH (1793-1862), a minister of state in Hesse-Cassel, celebrated as a reactionary, was born at Hanau, in the elec-

torate of Hesse, in 1793. He studied law at Göttingen, and was appointed by the elector Frederick William I. (then acting as regent) to a subordinate post in that university. He rose rapidly, and proved himself a man of great resolution and energy. From the first he adopted that line of policy which made him so disliked throughout his career. He exercised, that is to say, a suspicious censorship over the press; he reduced to a shadow the power of the legislative chambers; he introduced new and harsh measures of army discipline, and contended relentlessly with all disciples of free thought. In the matter of education he showed praiseworthy zeal, and promoted as far as he could the national schools of Hesse. But the services he rendered in this way were not sufficient to induce the mass of the people to pardon the reactionary tendency of his general policy, and he was obliged in 1837 to flee from the general hatred he had encountered. He found shelter in Prussia, where the Government entrusted him with the discharge of various judicial offices, and he remained in Prussia till the full tide of reaction had set in after the year 1848. He then (1850) returned to Hesse Cassel, the ministry of the revolution of 1848 having been dismissed. Despite the fact that Hassenpflug had never freed himself from a charge of peculation brought against him in the performance of his judicial duties in Prussia, he was appointed by the elector of Hesse to the head of the new ministry. He acted at once on the old lines, levying taxes without the consent of the chambers, dissolving them when they protested, and finally proclaiming martial law. The soldiers rose, the officers being on the side of the people; the Government was in so precarious a condition that it seemed wise to the elector to flee with his court to Wilhelmsbad. Partly by the influence of Hassenpflug the German bundesrath (or council of all the states) espoused the cause of the elector against his subjects, and by the end of the year (1850) the astute minister had the satisfaction of seeing the reactionary Government (with himself as minister of finance) reinstated in power. His position was, however, difficult, owing to his great unpopularity among all classes. When in 1852 the brother of the elector assaulted him in a fit of lunacy, Hassenpflug at once sent in his resignation, but it was not accepted till 1855. He then retired to Marburg (in Hesse), where he died October 15, 1862. His friend Dr Vilmar, who pronounced his funeral oration, dwelt chiefly on the piety of the deceased, who he said never travelled without a copy of the New Testament.

HASTINAPUR, an ancient city of India, in the Meerut district, North-Western Provinces, lying on the bank of the Burigangá, or former bed of the Ganges, 22 miles N.E. of Meerut. It formed the capital of the great Pándava kingdom, celebrated in the *Mahábhárata*, and probably one of the earliest Aryan settlements outside the Punjab. Few traces of the ancient city now remain, but tradition points to a group of shapeless mounds as the residence of the children of the moon, the Lunar princes of the house of Bhárata whose deeds are commemorated in the great national epic. After the conclusion of the famous war which forms the central episode of that poem, Hastinapur remained for some time the metropolis of the descendants of Parikshit, but the town was finally swept away by a flood of the Ganges, and the capital was transferred to Kausámbi.

HASTINGS, a municipal and parliamentary borough and market-town of Sussex, England, the principal of the Cinque Ports, is picturesquely situated on the southern coast of England, 74 miles from London by the London, Brighton, and South Coast Railway, and 62 by the London and South-Eastern Railway. It lies in two gorges, surrounded by an amphitheatre of hills and cliffs on every side except the south. At the beginning of the century, when

it first came into reputation as a watering-place, Hastings consisted of two main streets; but since then many new streets and squares have been added, and St Leonards, at that time about a mile distant, is now connected with it by a line of terraces and parades, and forms its more fashionable district. On the brink of the western cliff there still stand a square and a circular tower of the old castle, probably erected soon after the time of William the Conqueror, and the ruins, opened up by excavation in 1824, of the castle chapel, a transitional Norman structure 110 feet long, with a nave, chancel, and aisles. Besides the chapel, there was also at one time a college, both being under the control of a dean and secular canons. The deanery was at one time held by Thomas a Becket, and one of the canonries by William of Wykeham. The principal public buildings are the old parish churches of All Saints and St Clements, both in the Perpendicular style, the former containing in its register for 1619 the baptism of Titus Oates, whose father was rector of the parish, and the latter two brasses to Thomas Weekes (d. 1563) and John Bailey (d. 1592); the town-hall, erected in 1823; the music hall, erected in 1859; the assembly-room, the Roman Catholic college, the Augustinian monastery, and the Albert memorial and drinking fountain, erected in 1864. Among the industries of the town are fishing, boat-building, and coach-making; but its prosperity depends chiefly upon its reputation as a watering-place. Its popularity in this respect is owing to its historical interest, its picturesque situation, the many beautiful walks in the neighbourhood, its fine level sands, and its healthy climate, which, while bracing and vigorous in the higher parts of the town, is in its lower parts specially suited, from its mildness, for sufferers from pulmonary complaints. The town is well supplied with hotels, reading rooms, and pleasure gardens, and possesses a line of parades extending along the coast for nearly 3 miles. The Marina, a covered parade 600 feet in length, was built in 1825. There is a fine pier, opened in 1872, 900 feet in length, and possessing a pavilion capable of seating nearly 2000 persons. A public park, 70 acres in extent, is at present being laid out. The sewage of the town is conveyed a considerable distance out to sea before it is discharged. The area of the municipal borough is 1636 acres, and of the parliamentary borough 4617 acres. The population of the municipal borough in 1871 was 29,291, and of the parliamentary borough 33,337.

Hastings is of great antiquity, and was a place of some importance in the time of the Anglo-Saxons. Some derive its name from Hasten, a Danish pirate who ravaged that coast in the time of Alfred the Great. According to the French biographer of Edward the Confessor, it was so called from the hasty manner in which William renewed its fortifications. It is mentioned in the chronicles as *Hastingas*, and is reckoned as distinct from the shire of Sussex. In the Bayeux tapestry it is called *Hestinga-cestra*. A mint was established at it by Athelstan in 924, of which there is some notice in the Domesday Book. In 1049, according to the Worcester Chronicle, its seamen distinguished themselves in the pursuit of the pirate Swend after the murder of Beorn, and took two of his ships. Like the other principal seaports on the southern coast, it was garrisoned by Harold in view of the possible landing of William the Conqueror, to whom, however, it surrendered without striking a blow, and who selected it as the site of a permanent camp, and erected a wooden fortress on the cliff on which the castle was afterwards built. From this camp William, on the morning of October 14th, 1066, set out to meet Harold at Senlac Hill; and after his great victory there he returned to it, and remained encamped five days in the hope of receiving the homage of the English. The site of the original town is supposed to be now in great part covered by the sea. By a charter of William the Conqueror Hastings, together with Hythe, was added to the three previously incorporated ports of Sandwich, Dover, and Romney, and invested with certain privileges, the five being subsequently known as the "Cinque Ports." In the reign of Edward I. it was rated at 21 ships with 21 seamen in each, for the service of the king for fourteen days at his own charge. In 1877 the town was burned down by the French, but it was soon afterwards rebuilt. The harbour has fallen almost into disuse since the time of Elizabeth, when the wooden pier was destroyed by a storm; it does not now ad-

mit vessels above 100 tons burthen, and this only at full tide. The town received a charter of incorporation from Elizabeth in 1558, which was confirmed and enlarged by Charles II. In the 42d of Edward III. it obtained the privilege of returning two members to parliament.

HASTINGS, WARREN (1732-1818), the first governor-general of British India, was born on the 6th of December 1732 in the little hamlet of Churchhill in Oxfordshire. He came of a family which had been settled for many generations in the adjoining village of Daylesford; but his great-grandfather had sold the ancestral manor-house, and his grandfather had been unable to maintain himself in possession of the family living. His mother died a few days after giving him birth; his father, Pynaston Hastings, drifted away to perish obscurely in the West Indies. Thus unfortunate in his birth, young Hastings received the elements of education at a charity school in his native village. At the age of eight he was taken in charge by an elder brother of his father, Howard Hastings, who held a post in the customs. After spending two years at a private school at Newington Butts, he was moved to Westminster, where among his contemporaries occur the names of Lord Thurlow and Lord Shelburne, Sir Elijah Impey, and the poets Cowper and Churchill. In 1749, when his headmaster Dr Nichols was already anticipating for him a successful career at the university, his uncle died, leaving him to the care of Mr Chiswick, who was in the direction of the East India Company; and he determined to send his ward to seek his fortune as a "writer" in Bengal.

When Hastings landed at Calcutta in October 1750, the affairs of the East India Company were at a low ebb. Throughout the entire south of the peninsula French influence was predominant. The settlement of Fort St George or Madras, captured by force of arms, had only recently been restored in accordance with a clause of the peace of Aix-la-Chapelle. The lurid genius of Dupleix everywhere overshadowed the native imagination, and the star of Clive had scarcely yet risen above the horizon. The rivalry between the English and the French, which had already convulsed the south, did not penetrate to Bengal. That province was under the able government of Ali Vardi Khan, who peremptorily forbade the foreign settlers at Calcutta and Chandanagar to introduce feuds from Europe. The duties of a young "writer" were then such as are implied in the name. At an early date Hastings was placed in charge of an *aurang* or factory in the interior, where his duties would be to superintend the weaving of silk and cotton goods under a system of money advances. In 1755 he was transferred to Kásimbázár, the river-port of the native capital of Múrshidábád. In 1756 the old nawáb died, and was succeeded by his grandson Siráj-ud-Daulah, a spoilt boy of 19, whose name is indelibly associated with the tragedy of the Black Hole. When that passionate young prince, in revenge for a fancied wrong, resolved to drive the English out of Bengal, his first step was to occupy the fortified factory at Kásimbázár, and make prisoners of Hastings and his companions. Hastings was soon released at the intercession of the Dutch resident, and made use of his position at Múrshidábád to open negotiations with the English fugitives at Falta, the site of a Dutch factory near the mouth of the Hooghly. In later days he used to refer with pride to his services on this occasion, when he was first initiated into the wiles of Oriental diplomacy. After a while, he found it necessary to fly from the Mahometan court, and join the main body of the English at Falta. When the relieving force arrived from Madras under Colonel Clive and Admiral Watson, Hastings enrolled himself as a volunteer, and took part in the action which led to the recovery of Calcutta. Clive showed his appreciation of Hastings's merits, by appointing him in 1758 to the important post of resident at the court of Múrshid-

dabád. It was there that he first came into collision with the Bengálí Bráhmán, Nandkumar, whose subsequent fate throws so deep a shadow upon his own fair fame. During his three years of office as resident he was able to render not a few valuable services to the Company; but it is more important to observe that his name nowhere occurs in the official lists of those who derived pecuniary profit from the necessities and weakness of the native chiefs. In 1761 he was promoted to be member of council, under the presidency of Mr Vansittart, who had been introduced by Clive from Madras. The period of Vansittart's government has been truly described as "the most revolting page of our Indian history." The entire duties of administration were suffered to remain in the hands of the nawáb, while a few irresponsible English traders had drawn to themselves all real power. The members of council, the commanders of the troops, and the commercial residents plundered on a grand scale. The youngest servant of the Company claimed the right of trading on his own account, free from taxation and from local jurisdiction, not only for himself but also for every native subordinate whom he might permit to use his name. It was this exemption, threatening the very foundations of the Mussulman government, that finally led to a rupture with the nawáb. Macaulay, in his celebrated essay, has said that "of the conduct of Hastings at this time little is known." As a matter of fact, the book which Macaulay was professing to review describes at length the honourable part consistently taken by Hastings in opposition to the great majority of the council. Sometimes in conjunction only with Vansittart, sometimes absolutely alone, he protested unceasingly against the policy and practices of his colleagues. On one occasion he was stigmatized in a minute by Mr Batson with "having espoused the nawáb's cause, and as a hired solicitor defended all his actions, however dishonourable and detrimental to the Company." An altercation ensued. Batson gave him the lie, and struck him in the council chamber. When war was actually begun, Hastings officially recorded his previous resolution to have resigned, in order to repudiate responsibility for measures which he had always opposed. Waiting only for the decisive victory of Buxar over the allied forces of Bengal and Oudh, he resigned his seat and sailed for England in November 1764.

After fourteen years' residence in Bengal Hastings did not return home a rich man, estimated by the opportunities of his position. According to the custom of the time he had augmented his slender salary by private trade. At a later date, he was charged by Burke with having taken up profitable contracts for supplying bullocks for the use of the Company's troops. It is admitted that he conducted by means of agents a large business in timber in the Gangetic sandarbans. When at Falta he had married Mrs Campbell, the widow of an officer. She bore him two children, of whom one died in infancy at Múrhídadábád, and was shortly followed to the grave by her mother. Their common gravestone is in existence at the present day, bearing date July 11, 1759. The other child, a son, was sent to England, and also died shortly before his father's return. While at home Hastings is said to have attached himself to literary society; and it may be inferred from his own letters that he now made the personal acquaintance of Samuel Johnson and Lord Mansfield. In 1766 he was called upon to give evidence before a committee of the House of Commons upon the affairs of Bengal. The good sense and clearness of the views which he expressed caused attention to be paid to his desire to be again employed in India. His pecuniary affairs were embarrassed, partly from the liberality with which he had endowed his few surviving relatives. The great influence of Lord Clive was also exercised on his behalf. At last,

in the winter of 1768, he received the appointment of second in council at Madras. Among his companions on his voyage round the Cape were the Baron Imhoff, a speculative portrait painter, and his wife, a lady of some personal attractions and great social charm, who was destined henceforth to be Hastings's life-long companion. Of his two years' work at Madras it is needless to speak in detail. He won the good-will of his employers by devoting himself to the improvement of their manufacturing business, and he kept his hands clean from the prevalent taint of pecuniary transactions with the nawáb of the Carnatic. One fact of some interest is not generally known. He drew up a scheme for the construction of a pier at Madras, to avoid the dangers of landing through the surf, and instructed his brother-in-law in England to obtain estimates from the engineers Brindley and Smeaton.

In the beginning of 1772 his ambition was stimulated by the nomination to the second place in council at Bengal with a promise of the reversion of the governorship when Mr Cartier should retire. Since his departure from Bengal in 1764 the situation of affairs in that settlement had scarcely improved. The second governorship of Clive was marked by the transfer of the *diwání* or financial administration from the Mogul emperor to the Company, and by the enforcement of stringent regulations against the besetting sin of peculation. But Clive was followed by two inefficient successors; and in 1770 occurred the most terrible Indian famine on record, which is credibly estimated to have swept away one-third of the population. In April 1772 Warren Hastings took his seat as president of the council at Fort William. His first care was to carry out the instructions received from home, and effect a radical reform in the system of government. Clive's plan of governing through the agency of the native court had proved a failure. The directors were determined "to stand forth as *diwán*, and take upon themselves by their own servants the entire management of the revenues." All the officers of administration were transferred from Múrhídadábád to Calcutta, which Hastings boasted at this early date that he would make the first city in Asia. This reform involved the ruin of many native reputations, and for a second time brought Hastings into collision with the wily Bráhmán, Nandkumar. At the same time a new settlement of the land revenue on leases for five years was begun, and the police and military systems of the country were placed upon a new footing. Hastings was a man of immense industry, with an insatiable appetite for details. The whole of this large series of reforms was conducted under his own personal supervision, and upon no part of his multifarious labours did he dwell in his letters home with greater pride. As an independent measure of economy, the stipend paid to the titular nawáb of Bengal, who was then a minor, was reduced by one-half—to sixteen *lákhs* a year (say £160,000). Macaulay imputes this reduction to Hastings as a characteristic act of financial immorality; but in truth it had been expressly enjoined by the court of directors, in a despatch dated six months before he took up office. His pecuniary bargains with Sújah Daula, the nawáb wazír of Oudh, stand on a different basis. Hastings himself always regarded them as incidents in the general scheme of his foreign policy. The Mahrattas at this time had got possession of the person of the Mogul emperor, Sháh Alam, from whom Clive obtained the grant of Bengal in 1765, and to whom he assigned in return the districts of Allahábád and Kora and a tribute of £300,000. With the emperor in their camp, the Mahrattas were threatening the province of Oudh, and causing a large British force to be cantoned along the frontier for its defence. Warren Hastings, as a deliberate measure of policy, withheld the tribute due to the emperor,

and resold Allahábád and Kora to the wazir of Oudh. The Mahrattas retreated, and all danger for the time was dissipated by the death of their principal leader. The wazir now bethought him that he had a good opportunity for satisfying an old quarrel against the adjoining tribe of Rohillas, who had played fast and loose with him while the Mahratta army was at hand. The Rohillas were a race of Afghan origin, who had established themselves for some generations in a fertile tract west of Oudh, between the Himalayas and the Ganges, which still bears the name of Rohilkhand. They were not so much the occupiers of the soil, as a dominant caste of warriors and freebooters. But in those troubled days their title was as good as any to be found in India. After not a little hesitation, Hastings consented to allow the Company's troops to be used to further the ambitious designs of his Oudh ally, in consideration of a sum of money which relieved the ever-pressing wants of the Bengal treasury. The Rohillas were defeated in fair fight. Some of them fled the country; and so far as possible Hastings obtained terms for those who remained. The fighting, no doubt, on the part of the wazir was conducted with all the savagery of Oriental warfare; but there is no evidence that it was a war of extermination.

Meanwhile, the affairs of the East India Company had again come under the consideration of Parliament. The Regulating Act, passed by Lord North's ministry in 1773, effected considerable changes in the constitution of the Bengal Government. The council was reduced to four members with a governor-general, who were to exercise certain indefinite powers of control over the presidencies of Madras and Bombay. Hastings was named in the Act as governor-general for a term of five years. The council consisted of General Clavering and the Hon. Colonel Monson, two third-rate politicians of considerable parliamentary influence; Philip Francis, then only known as an able permanent official; and Barwell, of the Bengal Civil Service. At the same time a supreme court of judicature was appointed, composed of a chief and three puisne judges, to exercise an indeterminate jurisdiction at Calcutta. The chief-justice was Sir Elijah Impey, already mentioned as a schoolfellow of Hastings at Westminster. The whole tendency of the Regulating Act was to establish for the first time the influence of the crown, or rather of parliament, in Indian affairs. The new members of council disembarked at Calcutta on the 19th of October 1774; and on the following day commenced the long feud which scarcely terminated twenty-one years later with the acquittal of Warren Hastings by the House of Lords. Macaulay states that the members of council were put in ill-humour because their salute of guns was not proportionate to their dignity. In a contemporary letter Francis thus expresses the same petty feeling: "Surely Mr H. might have put on a ruffled shirt." Taking advantage of an ambiguous clause in their commission, the majority of the council (for Barwell uniformly sided with Hastings), forthwith proceeded to pass in review the recent measures of the governor-general. All that he had done they condemned; all that they could they reversed. Hastings was reduced to the position of a cipher at their meetings. After a time they lent a ready ear to detailed allegations of corruption brought against him by his old enemy Nandkumar. To charges from such a source, and brought in such a manner, Hastings disdained to reply, and referred his accuser to the supreme court. The majority of the council, in their executive capacity, resolved that the governor-general had been guilty of peculation, and ordered him to refund. A few days later Nandkumar was thrown into prison on a stale charge of forgery, tried before the supreme court sitting in bar, found guilty by a jury of Englishmen, and sentenced to be hanged. That Hastings set this prosecution in motion, no

reasonable person can doubt; and it is equally clear that Chief-Justice Impey is free from all personal blame. The majority of the council abandoned their supporter, who was executed in due course. He had forwarded a petition for reprieve to the council, which Clavering took care should not be presented in time, and which was subsequently burnt by the common hangman on the motion of Francis. At the time no one dared to impute to Hastings the crime of a judicial murder. But though he had thus silenced the charges brought against him, a combination of circumstances placed him in a position of fresh difficulty. While the strife was at its hottest, he had sent an agent to England, with a general authority to place his resignation in the hands of the Company under certain conditions. The agent thought fit to exercise that authority. The resignation was promptly accepted, and one of the directors was appointed to the vacancy. But in the meantime Colonel Monson had died, and Hastings was thus restored, by virtue of his casting vote, to the supreme management of affairs. He refused to ratify his resignation; and when Clavering attempted to seize on the governor-generalship, he judiciously obtained an opinion of the supreme court in his own favour. From that time forth, though he could not always command an absolute majority in council, Hastings was never again subjected to gross insult, and his general policy was able to prevail.

A crisis was now approaching in foreign affairs which demanded all the experience and all the genius of Hastings for its solution. Bengal was prosperous, and free from external enemies on every quarter. But the Government of Bombay had hurried on a rupture with the Mahratta confederacy at a time when France was on the point of declaring war against England, and when the mother-country found herself unable to subdue her rebellious colonies in America. Hastings did not hesitate to take upon his own shoulders the whole responsibility of military affairs. All the French settlements in India were promptly occupied. On the part of Bombay, the Mahratta war was conducted with procrastination and disgrace. But Hastings amply avenged the capitulation of Wárgáon by the complete success of his own plan of operations. Colonel Goddard with a Bengal army marched across the breadth of the peninsula, from the valley of the Ganges to the western sea, and achieved almost without a blow the conquest of Guzerát. Captain Popham, with a small detachment, stormed the rock fortress of Gwalior, then deemed impregnable and the key of Central India; and by this feat held in check Sindiá, the most formidable of the Mahratta chiefs. The bhonsla, or Mahratta rájá of Nágpur, whose dominions bordered on Bengal, was won over by the diplomacy of an emissary of Hastings. But while these events were taking place, a new source of embarrassment had arisen at Calcutta. The supreme court, whether rightly or wrongly, assumed a jurisdiction of first instance over the entire province of Bengal. The English common law, with all the absurdities and rigours of that day, was arbitrarily extended to an alien system of society. *Zamindárs*, or government renters, were arrested on mesne process; the sanctity of the *zanána*, or women's chamber, as dear to Hindus as to Mahometans, was violated by the sheriff's officer; the deepest feelings of the people and the entire fabric of revenue administration were alike disregarded. On this point the entire council acted in harmony. Hastings and Francis went joint-bail for imprisoned natives of distinction. At last, after the dispute between the judges and the executive threatened to become a trial of armed force, Hastings set it at rest by a characteristic stroke of policy. A new judicial office was created in the name of the Company, to which Sir Elijah Impey was appointed, though he never consented to draw the additional salary

offered to him. The understanding between Hastings and Francis, originating in this state of affairs, was for a short period extended to general policy. An agreement was come to by which Francis received patronage for his circle of friends, while Hastings was to be unimpeded in the control of foreign affairs. But a difference of interpretation arose. Hastings recorded in an official minute that he had found Francis's private and public conduct to be "void of truth and honour." They met as duellists. Francis fell wounded, and soon afterwards returned to England.

The Mahratta war was not yet terminated, but a far more formidable danger now threatened the English in India. The imprudent conduct of the Madras authorities had irritated beyond endurance the two greatest Mussulman powers in the peninsula, the nizám of the Deccan and Hyder Ali, the usurper of Mysore, who began to negotiate an alliance with the Mahrattas. A second time the genius of Hastings saved the British empire in the east. On the arrival of the news that Hyder had descended from the highlands of Mysore, cut to pieces the only British army in the field, and swept the Carnatic up to the gates of Madras, he at once adopted a policy of extraordinary boldness. He signed a blank treaty of peace with the Mahrattas, who were still in arms, reversed the action of the Madras Government towards the nizám, and concentrated all the resources of Bengal against Hyder Ali. Sir Eyre Coote, a general of renown in former Carnatic wars, was sent by sea to Madras with all the troops and treasure that could be got together; and a strong body of reinforcements subsequently marched southwards under General Leslie along the coast line of Oríssa. The landing of Coote preserved Madras from destruction, though the war lasted through many campaigns and only terminated with the death of Hyder. Leslie's detachment was decimated by an epidemic of cholera (perhaps the first mention of this disease by name in Indian history); but the survivors penetrated to Madras, and not only held in check the bhonsla and the nizám, but also corroborated the lesson taught by Goddard—that the Company's sepoy could march anywhere, when boldly led. Hastings's personal task was to provide the ways and means for this exhausting war. A considerable economy was effected by a reform in the establishment for collecting the land tax. The Government monopolies of opium and salt were then for the first time placed upon a remunerative basis. But these reforms were of necessity slow in their beneficial operation. The pressing demands of the military chest had to be satisfied by loans, and in at least one case from the private purse of the governor-general. Ready cash could alone fill up the void; and it was to the hoards of native princes that Hastings's fertile mind at once turned. Cheyte Sing, rájá of Benares, the greatest of the vassal chiefs who had grown rich under the protection of the British rule, lay under the suspicion of disloyalty. The wazír of Oudh had fallen into arrears in the payment due for the maintenance of the Company's garrison posted in his dominions, and his administration was in great disorder. In his case the ancestral hoards were under the control of his mother, the begum of Oudh, into whose hands they had been allowed to pass at the time when Hastings was powerless in council. Hastings resolved to make a progress up country in order to arrange the affairs of both provinces, and bring back all the treasure that could be squeezed out of its holders by his personal intervention. When he reached Benares and presented his demands, the rájá rose in insurrection, and the governor-general barely escaped with his life. But the faithful Popham rapidly rallied a force for his defence. The native soldiery were defeated again and again; Cheyte Sing took to flight, and an augmented permanent tribute was imposed upon his successor. The Oudh business was

managed with less risk. The wazír consented to everything demanded of him. The begum was charged with having abetted Cheyte Sing in his rebellion; and after the severest pressure applied to herself and her attendant eunuchs, a fine of more than a million sterling was exacted from her. Hastings appears to have been not altogether satisfied with the incidents of this expedition, and to have anticipated the censure which it received in England. As a measure of precaution, he procured documentary evidence of the rebellious intentions of the rájá and the begum, to the validity of which Impey obligingly lent his extra-judicial sanction.

The remainder of Hastings's term of office in India was passed in comparative tranquillity, both from internal opposition and foreign war. The centre of interest now shifts to the India House and to the British Parliament. The long struggle between the Company and the ministers of the crown for the supreme control of Indian affairs and the attendant patronage had reached its climax. The decisive success of Hastings's administration alone postponed the inevitable solution. His original term of five years would have expired in 1778; but it was annually prolonged by special Act of Parliament until his voluntary resignation. Though Hastings was thus irremovably his policy did not escape censure. Ministers were naturally anxious to obtain the reversion to his vacant post, and Indian affairs formed at this time the hinge on which party politics turned. On one occasion Dundas carried a motion in the House of Commons censuring Hastings, and demanding his recall. The directors of the Company were disposed to act upon this resolution; but in the court of proprietors, with whom the decision ultimately lay, Hastings always possessed a sufficient majority. Fox's India Bill led to the downfall of the Coalition Ministry in 1783. The Act which Pitt successfully carried in the following year introduced a new constitution, in which Hastings felt that he had no place. In February 1785 he finally sailed from Calcutta, after a dignified ceremony of resignation, and amid enthusiastic farewells from all classes.

On his arrival in England, after a second absence of sixteen years, he was not displeased with the reception he met with at court and in the country. A peerage was openly talked of as his due, while his own ambition pointed to some responsible office at home. Pitt had never taken a side against him, while Lord Chancellor Thurlow was his pronounced friend. But he was now destined to learn that his enemy Francis, whom he had discomfited in the council chamber at Calcutta, was more than his match in the parliamentary arena. Edmund Burke had taken the subject races of India under the protection of his eloquence. Francis, who had been the early friend of Burke, supplied him with the personal animus against Hastings, and with the knowledge of details, which he might otherwise have lacked. The Whig party on this occasion unanimously followed Burke's lead. Dundas, Pitt's favourite subordinate, had already committed himself by his earlier resolution of censure; and Pitt was induced by motives which are still obscure to incline the ministerial majority to the same side. To meet the oratory of Burke and Sheridan and Fox, Hastings wrote an elaborate minute with which he wearied the ears of the House for two successive nights, and he subsidized a swarm of pamphleteers. The impeachment was decided upon in 1786, but the actual trial did not commence until 1788. For seven long years Hastings was upon his defence on the charge of "high crimes and misdemeanours." During this anxious period he appears to have borne himself with characteristic dignity, such as is consistent with no other hypothesis than the consciousness of innocence. At last, in 1795, the House of Lords gave a verdict of not guilty on all the charges laid against him; and he left the bar at

which he had so frequently appeared, with his reputation clear, but ruined in fortune. However large the wealth he brought back from India, all was swallowed up in defraying the expenses of his trial. Continuing the line of conduct which in most other men would be called hypocrisy, he forwarded a petition to Pitt praying that he might be reimbursed his costs from the public funds. This petition, of course, was rejected. At last, when he was reduced to actual destitution, it was arranged that the East India Company should grant him an annuity of £4000 for a term of years, with £90,000 paid down in advance. This annuity expired before his death; and he was compelled to make more than one fresh appeal to the bounty of the Company, which was never withheld. Shortly before his acquittal he had been able to satisfy the dream of childhood, by buying back the ancestral manor of Daylesford, where the remainder of his life was passed in honourable retirement. In 1813 he was called on to give evidence upon Indian affairs before the two Houses of Parliament, which received him with exceptional marks of respect. The university of Oxford conferred on him the honorary degree of D.C.L.; and in the following year he was sworn of the Privy Council, and took a prominent part in the reception given to the duke of Wellington and the allied sovereigns. He died on the 22d of August 1818, in his 86th year, and lies buried behind the chancel of the parish church, which he had recently restored at his own charges.

In physical appearance, Hastings "looked like a great man, and not like a bad man." The body was wholly subjugated to the mind. A frame naturally slight had been further attenuated by rigorous habits of temperance, and thus rendered proof against the diseases of the tropics. Against his private character not even calumny has breathed a reproach. As brother, as husband, and as friend, his affections were as steadfast as they were warm. By the public he was always regarded as reserved, but within his own inner circle he gave and received perfect confidence. In his dealings with money, he was characterized rather by liberality of expenditure than by carefulness of acquisition. A classical education and the instincts of family pride saved him from both the grood and the vulgar display which marked the typical "nabob," the self-made man of those days. He could support the position of a governor-general and of a country gentleman with equal credit. Concerning his second marriage, it suffices to say that the Baroness Imhoff was about forty years of age, with a family of grown-up children, when the complaisant law of her native land allowed her to become Mrs Hastings. She survived her husband, who seems to have cherished towards her, to the last the sentiments of a lover. Her children he adopted as his own; and it was chiefly for her sake that he desired the peerage which was twice held out to him.

Hastings's public career will probably never cease to be a subject of controversy. It was his misfortune to be the scape-goat upon whose head Parliament laid the accumulated sins, real and imaginary, of the East India Company. If the acquisition of our Indian empire can be supported on ethical grounds, Hastings needs no defence. No one who reads his private correspondence will admit that even his least defensible acts were dictated by dishonourable motives. It is more pleasing to point out certain of his public measures upon which no difference of opinion can arise. He was the first to attempt to open a trade route with Thibet, and to organize a survey of Bengal and of the eastern seas. It was he who persuaded the *pandits* of Bengal to disclose the treasures of Sanskrit to European scholars. He founded the Madrasa or college for Mahometan education at Calcutta, primarily out of his own funds; and he projected the foundation of an Indian

Institute in England. The Royal Asiatic Society was established under his auspices, though he yielded the post of president to Sir W. Jones. No Englishman ever understood the native character so well as Hastings; none ever devoted himself more heartily to the promotion of every acheme, great and small, that could advance the prosperity of India. Natives and Anglo-Indians alike venerate his name, the former as their first beneficent administrator, the latter as the most able and the most enlightened of their own class. If Clive's sword conquered the Indian empire, it was the brain of Hastings that planned the system of civil administration, and his genius that saved the empire in its darkest hour.

The bibliography dealing with Warren Hastings is not large. The histories of Mill and Thornton both adopt a standpoint that is on the whole adverse. The *Memoirs*, by Gleig, in 3 vols. (Lond., 1841) are too tedious to be read at the present day. The review of those *Memoirs* by Macaulay, despite its exuberance of colour, its Whig partiality, and its proved inaccuracies, will not easily be superseded as the one standard authority. There is a recent *Biography* by Captain Trotter (1878). Much interesting information, in correction or amplification of Macaulay, may be found in the *Memoirs of Francis, with Correspondence, &c.*, by Parkes and H. Merivale (1867), and in the *Memoirs of Sir E. Impey* by his son (1846), who deposited his private MS. materials in the British Museum. In 1872 the British Museum also obtained by purchase from a Mrs Kiuter 268 vols. of papers relating to Hastings, chiefly letters between 1757 and 1818. These have been partly utilized by Mr Beveridge in a series of articles contributed to the *Calcutta Review* for October 1877, April 1878, and April 1879. (J. S. C.)

HASTINGS, FRANCIS RAWDON HASTINGS, FIRST MARQUIS OF (1754-1826), ranks among those governors-general of India who, completing the work of Clive and Warren Hastings, achieved the creation of the Indian empire of England. The services of Lord Hastings in this respect were special and important. He was both governor-general and commander-in-chief in India from 1813 till the end of 1822; during that period he carried two important wars, the Nepaulese and the Mahratta, to a successful issue; while adding to the territories of the East India Company, he in several respects altered and improved their policy; and by the sagacity and at the same time the generosity of his own administration (in which he exhibited the true qualities of a Christian proconsul) he won reverence from the natives and left a great name in India.

Lord Hastings was in no way connected with Warren Hastings; his family name was Rawdon. His father, Sir John Rawdon of Moira in the county of Down, fourth baronet, was created Baron Rawdon of Moira, and afterwards Earl of Moira, in the Irish peerage. His mother was the Lady Elizabeth Hastings, daughter of the ninth earl of Huntingdon. Both his father and mother appear to have been persons of considerable ability and high cultivation. Lord Rawdon, as he was then called, having gone at an early age to the university of Oxford, joined the army in his seventeenth year as ensign in the 15th foot. His life henteforth was entirely spent in the service of his country, and may naturally be divided into four periods:— from 1773 to 1782 he was engaged with much distinction in the American war; from 1783 to 1813 he held various high appointments at home, and took an active part in the business of the House of Lords; from 1813 to 1823 was the period of his labours in India; after retiring from which, in the last years of his life (1824-1826), he was governor of Malta.

In America Lord Rawdon served at the battles of Bunker's Hill, Brooklyn, White Plains, Monmouth, and Camden, at the attacks on Forts Washington and Clinton, and at the siege of Charleston. In fact he was engaged in all the chief operations of the war. Perhaps his most noted achievements were the raising of a corps at Philadelphia, called the Irish Volunteers, who under him became famous for their fighting qualities, and the victory of Hob-

kirk Hill, which, when in command of only a small force, he gained by superior military skill and determination against an American *corps d'armée*. In 1782 he was invalided. The vessel in which he returned to England was captured and carried into Brest. This occasioned the loss of his papers and personal records of the war which would doubtless have been interesting. He was speedily released, and on his arrival in England was much honoured by George III., who created him an English peer (Baron Rawdon) in March 1783.

In 1793 Lord Rawdon succeeded his father as earl of Moira. In 1794 he was sent with 10,000 men from Southampton to Ostend to reinforce the duke of York and the allies in Flanders. The march by which he effected a junction was considered extraordinary. In 1803 he was appointed commander-in-chief in Scotland, and in 1804 he married Flora Muir Campbell, countess of Loudon in her own right. He and Lady Loudon lived at Duddingston House near Edinburgh, where they were very popular. The opposition coming into power in 1806, Lord Moira, who had always voted with them, received the place of master general of the ordnance. He was now enabled to carry a philanthropic measure, of which from his first entry into the House of Lords he had been a great promoter, namely, the Debtor and Creditor Bill for relief of poor debtors. Ireland was another subject to which he had given particular attention: in 1797 there was published a *Speech by Lord Moira on the Dreadful and Alarming State of Ireland*. Lord Moira's sound judgment on public affairs, combined with his military reputation and the honourable uprightness of his character, won for him a high position among the statesmen of the day, and he gained an additional *prestige* from his intimate relations with the prince of Wales. On two occasions, in 1809 and again in 1812 after the assassination of Percival, there were negotiations for placing him at the head of affairs. As a further mark of the regent's regard Lord Moira received the order of the Garter, and in the same year was appointed governor-general and commander-in-chief of India. He landed at Calcutta, and assumed office in succession to Lord Minto in October 1813. He was now fifty-nine years of age. One of the chief questions which awaited him was that of relations with the Goorkha state of Nepal. The Goorkhas, a brave and warlike little nation, failing to extend their conquests in the direction of China, had begun to encroach on territories held or protected by the East India Company; especially they had seized the districts of Bootwal and Seoraj, in the northern part of Oudh, and when called upon to relinquish these, they deliberately elected (April 1814) to go to war rather than do so. Lord Moira, having travelled through the northern provinces and fully studied the question, declared war against Nepal (November 1814). The enemy's frontier was 600 miles long, and Lord Moira, who directed the plan of the campaign, resolved to act offensively along the whole line. It was an anxious undertaking, because the native states of India were all watching the issue and waiting for any serious reverse to the English to join against them. At first all seemed to go badly, as the British officers too much despised the enemy, and the Sepoys were unaccustomed to mountain warfare, and thus alternate extremes of rashness and despondency were exhibited. But this rectified itself in time, especially through the achievements of General (afterwards Sir David) Ochterlony, who before the end of 1815 had taken all the Goorkha posts to the west, and early in 1816 was advancing victoriously within 50 miles of Katmandoo, the capital. The Goorkhas now made peace; they abandoned the disputed districts, ceded some territory to the English, and agreed to receive a British resident. Ever since they have faithfully kept these terms; the northern frontier of India

has been securely fixed, and the Goorkhas have entirely kept aloof from the machinations of disaffected native states. For his masterly conduct of these affairs Lord Moira was created Marquis of Hastings in 1816.

He had now to deal with internal dangers. A treacherous combination of Mahratta powers was constantly threatening the continuance of British rule, under the guise of plausible assurances severally given by the peshwah, Sindia, Holkar, and other princes. At the same time the existence of the Pindháree state was not only dangerous to the English, as being a warlike power always ready to turn against them, but it was a scourge to India itself. In 1816, however, the Pindhárees entered British territory in the Northern Circars, where they destroyed 339 villages. On this, permission was obtained to act for their suppression. Before the end of 1817 the preparations of Lord Hastings were completed, when the peshwah suddenly broke into war, and the British were opposed at once to the Mahratta and Pindháree powers, estimated at 200,000 men and 500 guns. "The whole was utterly shattered in a brief campaign¹ of four months (1817-1818)." The peshwah's dominion had been annexed, and those of Sindia, Holkar, and the rajah of Berar lay at the mercy of the governor-general, and were saved only by his exceeding and honourable moderation. There was at last, after sixty years from the battle of Plassy, no question of the supremacy of British power in India, now more perfectly established and more effectively dominant than that of Aurungzebe.² The Pindhárees had ceased to exist, and peace and security had been substituted for misery and terror.

"It is a proud phrase to use," said Lord Hastings,³ "but it is a true one, that we have bestowed blessings upon millions. Nothing can be more delightful than the reports I receive of the sensibility manifested by the inhabitants to this change in their circumstances. The smallest detachment of our troops cannot pass through that district without meeting everywhere eager and exulting gratulations, the tone of which proves them to come from glowing hearts. Multitudes of people have, even in this short interval, come from the hills and fastnesses in which they had sought refuge for years, and have reoccupied their ancient deserted villages. The ploughshare is again in every quarter turning up a soil which had for many seasons never been stirred, except by the hoofs of predatory cavalry."

While the natives of India appreciated the results of Lord Hastings's achievements, the court of directors grumbled at his having extended the British territory. They also disliked and opposed his measures for introducing education among the natives and his encouraging the freedom of the press. Posterity has, however, vindicated the policy of Lord Hastings in all respects. In 1819 he obtained the cession by purchase of the island of Singapore. In finance his administration was very successful, as notwithstanding the expenses of his wars he showed an annual surplus of two millions sterling. He laboured much at law reform, and he succeeded in greatly raising the status and character of the civil service of India. Lord and Lady Hastings by their stately and yet genial manners, and by their warm encouragement of literature and science, gave a high tone to the society of Calcutta. And he was the first governor-general to exhibit a personal interest in the exertions of the missionaries. Brilliant and beneficent as his career had been, Lord Hastings did not escape any more than Clive, Warren Hastings, or Lord Wellesley, the assaults of unjust detraction. His last years of office were embittered by the discussions on a matter very notorious

¹ For the interesting details of this campaign, as well as of the war in Nepal, see Prinsep's *History of the Political and Military Transactions in India, during the administration of the Marquis of Hastings*.

³ Reply to Address of Inhabitants of Calcutta; see *Asiatic Journal*, February 1819.

at the time, namely, the affairs of the banking-house of W. Palmer and Company. The whole affair was mixed up with insinuations against Lord Hastings, especially charging him with having been actuated by favouritism towards one of the partners in the firm. From imputations which were inconsistent with his whole character he has subsequently been exonerated. But while smarting under them he tendered his resignation in 1821, though he did not leave India till January 1823. He was much exhausted by the arduous and almost incredible labours which for more than nine years he had sustained. Among his characteristics it is mentioned that "his ample fortune absolutely sank under the benevolence of his nature;" and, so far from having enriched himself in the appointment of governor-general, he returned to England in circumstances which obliged him still to seek public employment. In 1824 he received the comparatively small post of governor of Malta, in which island he introduced many reforms and endeared himself to the inhabitants. He died in 1826, leaving a request that his right hand should be cut off and preserved till the death of the marchioness of Hastings, and then interred in her coffin.

No "Life" of the marquis of Hastings has appeared, but a diary of his first tours in India, written for his children, has been published, and affords interesting indications of his character. For further particulars of his career see the *Asiatic Journal* for November 1823, and the *Annual Biography and Obituary* for 1823; and for details of his Indian administration see Prinsep's work cited above, Wilson's continuation of Mill's *History of India*, and other Indian histories. (A. GR.)

HAT, a covering for the head worn by both sexes, and distinguished from the cap or bonnet by the possession of a brim. The modern hat can be traced back to the *petasus* worn by the ancient Romans when on a journey; and hats with brims were also used, probably on like occasions, by the earlier Greeks. It was not till after the Norman conquest that the use of hats began in England. A "hatte of biever" about the middle of the 12th century was worn by some one of the "nobels of the lande, mett at Clarendom;" and Froissart describes hats and plumes which were worn at Edward's court in 1340, when the Garter order was instituted. In the 13th century the use of the scarlet hat which distinguishes cardinals was sanctioned by Pope Innocent IV. The merchant in Chaucer's *Canterbury Tales* had

"On his head a Flaundrish bever hat;"

and from that period onwards there is frequent mention of "felt hattes," "beever hattes," and other like names. Throughout mediæval times the wearing of a hat was regarded as a mark of rank and distinction. The caprices of fashion in hats during the reign of Elizabeth may be understood from an extract from Stubbs's *Anatomie of Abuses*, published about 1585:—

"Sometimes they use them sharpe on the crowne pearking up like the spire or shaft of a steeple, standing a quarter of a yard above the crowne of their heads; some more, some lesse, as please the fantasies of their inconstant mindes. Othersome be flat, and broad on the crowne, like the battlements of a house. Another sorte have rounde crownes, sometimes with one kind of bande, sometimes with another; now black, now white, now russet, now redde, now grene, now yellow; now this, now that; never content with one colour or fashion two daies to an end."

During the reign of Charles I. the Puritans affected a steeple crown and broad-brimmed hat, while the Cavaliers adopted a lower crown and a broader brim ornamented with feathers. Still greater breadth of brim and a profusion of feathers were fashionable characteristics of the hats in the time of Charles II., and the gradual expansion of brim led to the device of looping or tying up that portion. Hence arose various fashionable "cocks" in hats, such as the "Monmouth cock," &c.; and ultimately, by the looping up equally of three sides of the low crowned hat, the cocked hat which prevailed throughout the 18th century was elaborated.

Since the beginning of the present century the cocked hat as an ordinary article of dress has disappeared. The Quaker hat, plain, low in crown, and broad in brim, which originated with the sect in the middle of the 17th century, is also now becoming uncommon. See COSTUME.

HAT MANUFACTURE.—Until recent times hats were principally made by the process of felting, and as tradition ascribed the discovery of that very ancient operation to St Clement, he was assumed as the patron saint of the craft, and the annual festival of the trade continues to be held on St Clement's day, the 23d November. At the present day the trade is divided into two distinct classes. The first and most ancient is concerned with the manufacture of felt hats, and the second has to do with the recent but now most extensive and important manufacture of silk or dress hats. In addition to these there is the equally important manufacture of straw or plaited hats, which does not fall within the scope of this article; and hats are occasionally manufactured of materials and by processes not included under any of these heads, but such manufactures do not take a large or permanent position in the industry.

Felt Hats.—As now made, felt hats are of three different kinds, plain soft, plain hard, and "napped" or "ruffed" felts. There is a great range in the quality of felt hats, the finer and more expensive qualities being made entirely of fur; for commoner qualities a mixture of fur and Saxony wool is used; and for the lowest kinds wool alone is employed. The processes and apparatus necessary for making hats of fur differ also from those required in the case of woollen bodies; and in large manufactories machinery is now generally employed for operations which at no distant date were entirely manual. In the smaller factories, and for special objects, the old hand processes are still in operation. An outline of the operations by which the old beaver hat was and to some extent yet is made will give an idea of the manual processes in making a fur napped hat, and the apparatus and mechanical processes employed in making ordinary hard and soft felts will afterwards be noticed.

Hatters' fur consists principally of the hair of rabbits (technically called coney) and hares, with some proportion of nutria, musquash, and beavers' hair; and generally any parings and cuttings from furriers are also used. Furs intended for felting are deprived of their long coarse hairs, after which they are treated with a solution of nitrate of mercury, an operation called *carroting* or *secretage*, whereby the felting properties of the fur are greatly increased. The fur is then cut by hand or machine from the skin, and in this state it is delivered to the hat maker. Rabbits' fur for hat-making now comes in large quantities from the Australian colonies; and it is also largely collected in the United Kingdom and in northern Europe. A considerable trade in rabbit fur for hat-making is maintained between Great Britain and the United States.

The old process of making a beaver hat is as follows. The materials of a proper beaver consist, for the body or foundation, of rabbits' fur, and for the nap, of beaver fur, although the beaver is often mixed with or supplanted by a more common fur. Such a hat may be regarded as the highest achievement of the hatter. In preparing the fur plate, the latter weighs out a sufficient quantity

Fig. 1.

of rabbit fur for a single hat, which is spread out and combined by the operation of bowing. The bow or stang ABC (fig. 1) is about 7 feet long, and it stretches a single cord of catgut D, which the workman vibrates by means of a wooden pin E, furnished with a half knob at each end. Holding the bow in his left hand, and the pin in his right, he causes the vibrating string to come in contact with the heap of tangled fur, which does not cover a space greater than that

of the head. At each vibration some of the filaments start up to the height of a few inches, and fall away from the mass, a little to the right of the bow, their excursions being restrained by a concave frame of wicker work called the basket. One half of the material is first operated on, and by bowing and gathering, or a patting use of the basket, the stuff is loosely matted into a triangular figure, about 50 by 36 inches, called a bat. In this formation care is taken to work about two-thirds of the fur down towards what is intended for the brim, which being effected, greater density is induced by gentle pressure with the basket. It is then covered with a wet lichen cloth, upon which is laid the hardening skin, a piece of dry half-tanned horse hide. On this the workman presses or bakes until the stuff adheres closely to the damp cloth, in which it is then doubled up, freely pressed with the hand, and laid aside. By this process, called basoning, the bat has become compactly felted and thinned toward the sides and point. The other half of the fur is next subjected to precisely the same processes, after which a cone-shaped slip of stiff paper is laid on its surface, and the sides of the bat are folded over its edges to its form and size. It is then laid paper-side downward upon the first bat, which is now replaced on the hurdle, and its edges are transversely doubled over the inverted side-laps of the second bat, thus giving equal thickness to the whole body. In this condition it is reintroduced between folds of damp lichen cloth, and again hardened, so as to unite the two halves, the knitting together of which is quickly effected. The paper is now withdrawn; and the body in the form of a large cone is removed to the plank or battery room.

The battery consists of an open iron boiler or kettle A (fig. 2), filled with scalding hot water, with shelves B, C, partly of mahogany and partly of lead, sloping down to it. Here the body is first dipped in the water, and then withdrawn to the plank to partly cool and drain, when it is unfolded, rolled gently with a pin tapering towards the ends, turned, and worked in every direction, to toughen and shrink it, and at the same time prevent adhesion of its sides. Stopping or thickening the thin spots which now appear, on looking through the body,

Fig. 2.

is carefully performed by dabbing on additional stuff in successive supplies from the hot liquor with a brush frequently dipped into the kettle, until the body be shrunk sufficiently (about one half) and thoroughly equalized. When quite dried, stiffening is performed with a brush dipped into a thin varnish of shellac, and rubbed into the body, the surface intended for the inside having much more laid on it than the outer, while the brim is made to absorb many times the quantity applied to any other part.

On being again dried, the body is ready to be covered with a nap of beaver hair. For this, in inferior qualities, the hair of the otter, nutria, or other fine fur is sometimes substituted. The requisite quantity of one or other of these is taken and mixed with a proportion of cotton, and the whole is bowed up into a thin uniform lap. The cotton merely serves to give sufficient body to the material to enable the workman to handle the lap. The body of the hat being damped, the workman spreads over it a covering of this lap, and by moistening and gentle patting with a brush the cut ends of the hair penetrate and fix themselves in the felt body. The hat is now put into a coarse hair cloth, dipped and rolled in the hot liquor until the fur is quite worked in, the cotton being left on the surface loose and ready for removal. The blocking, dyeing, and finishing processes in the case of beaver hats are similar to those employed for ordinary felts, except that greater care and dexterity are required on the part of the workmen, and further that the coarse hairs or kemps which may be in the fur are cut off by shaving the surface with a razor. The nap also must be laid in one direction, smoothed, and rendered glossy by repeated wettings, ironings, and brushings. A hat so finished is very durable, and it is much more light, cool, and easy-fitting to the head than the silk hat which has now so largely superseded it.

Till a comparatively recent date all attempts to apply machinery to the principal processes in felt hat-making resulted in failure. As is the case with many other labour-saving appliances of recent introduction, the first efficient machinery for felt hat-making was

devised in America, and from the United States the machine-making processes were introduced into England about the year 1859; and now in all large establishments machinery such as that alluded to below is employed. For the forming of hat bodies two kinds of machine are used, according as the material employed is fur or wool. In the case of fur, the essential portion of the apparatus used consists of a cone of copper of the size and form of the body or bat to be made, perforated all over with small holes. The cone is made to revolve on its axis slowly over an orifice under which there is a powerful fan, which maintains a strong inward draught of air through the holes in the cone. At the side of the cone, and with an opening towards it, is a trunk or box from which the fur to be made into a hat is thrown out by the rapid revolution of a brush-like cylinder, and as the cloud of separate hairs is expelled from the trunk, the current of air being sucked through the cone carries the fibres to it and causes them to cling closely to its surface. Thus a coating of loose fibres is accumulated on the copper cone, and these are kept in position only by the exhaust at work under it. When sufficient for a hat body has been deposited, a wet cloth is wrapped round it, over which an outer cone is slipped and the whole is removed for felting, while another copper cone is placed in position for continuing the work. The felting of fur bodies is principally done by hand-labour, although machinery has recently been introduced by which it is partly done. The bat or body of wool hats is prepared by first carding in a modified form of carding machine. The wool is divided into two separate slivers as delivered from the cards, and these are wound simultaneously on a double conical block of wood mounted and geared to revolve slowly with a reciprocating horizontal motion, so that there is a continual crossing and recrossing of the wool as the sliver is wound around the cone. This diagonal arrangement of the sliver is an essential feature in the apparatus, as thereby the strength of the finished felt is made equal in every direction; and when strained in the blocking the texture yields in a uniform manner without rupture. The wool wound on the double block forms the material of two hats, which are separated by cutting around the median or base line, and slipping each half off at its own end. Into each cone of wool or bat an "inlayer" is now placed to prevent the inside from matting, after which they are folded in cloths, and placed over a perforated iron plate through which steam is blown. When well moistened and heated, they are placed between boards, and subjected to a rubbing action sufficient to harden them for bearing the subsequent strong planking or felting operations. The planking of wool hats is generally done by machine, in some cases a form of fulling mill being used; but in all forms the agency is heat, moisture, pressure, rubbing, and turning.

When by thorough felting the hat bodies of any kind have been reduced to dense leathery cones about one-half the size of the original bat, they are dried, and, if hard felts are to be made, the bodies are at this stage hardened or stiffened with a varnish of shellac. Next follows the operation of blocking, in which the felt for the first time assumes approximately the form it is ultimately to possess. For this purpose the conical body is softened in boiling water, and forcibly drawn over a hat-shaped wooden block. A string is passed round where the band is to be, and the brim is then flattened out from the string. Next follows the dyeing of the hat in a bath of suitable dyeing materials, according to the colour desired. In dealing with fine hats, each hat is separately dyed while on the block, but with commoner qualities it is the practice to dye before blocking. The finishing processes include slapping on a block, over which crown and brim receive accurately their ultimate form, and pouncing or pumicing, which consists of smoothing the whole surface with emery or glass paper while the hat is still stretched on the block. The trimmer finally binds the outer brim and inserts the lining, after which the brim may get more or less of a curl or turn over according to prevailing fashion. Machines of American invention for blocking and pouncing have to some extent been introduced.

Silk Hats.—The silk hat, which has now become co-extensive with civilization, is an article of recent introduction. It was known in Florence about a century ago; but its manufacture was not introduced into France till about 1825, and its development has taken place entirely since that period. A silk hat consists of a light stiff body covered with a plush of silk, the manufacture of which in a brilliant glossy condition is the most important element in the industry; and in that manufacture the French are without equals. Originally the bodies were made of felt and various other materials, but now calico is almost exclusively used.

The calico is first stiffened with a varnish of shellac, and then cut into pieces sufficient for crown, side, and brim. The side-piece is wound round a wooden hat block, and its edges are joined by hot ironing, and the crown-piece is put on and similarly attached to

the side. The brim, consisting of three thicknesses of calico cemented together, is now slipped over and brought to its position, and thereafter a second side-piece and another crown are cemented on. The whole of the body, thus prepared, now receives a coat of size, and subsequently it is varnished over, and thus it is ready for the operation of covering. In covering this body, the under brim, generally of merino, is first attached, then the upper brim, and lastly the crown and side sewn together are drawn over. All these by hot ironing and stretching are drawn smooth and tight, and as the varnish of the body softens with the heat, body and cover adhere all over to each other without wrinkle or pucker. Dressing and polishing by means of damping, brushing, and ironing, come next, after which the hat is "velured" in a revolving machine by the application of haircloth and velvet velures, which cleans the nap and gives it a smooth and glossy surface. The brim has only then to be bound, the linings inserted, and the brim finally curled, when the hat is ready for use.

In all kinds of hat-making the French excel, and in such centres as Anduze, Lyons, and Paris the trade is very extensive and important. In the United Kingdom the felt-hat trade is principally centred at Denton and other localities in the neighbourhood of Manchester, and in America the States of New York and New Jersey enjoy the greater part of the industry. The value of the hats annually exported from the United Kingdom somewhat exceeds £1,000,000 sterling. (J. PA.)

HATFIELD, or **BISHOP'S HATFIELD**, a quiet, old-fashioned market-town of England, in the county of Hertford, is prettily situated on the side of a hill, 17 $\frac{3}{4}$ miles N.N.W. of London by railway. The church of St Ethelreda dates its foundation from Norman times, though only a small portion of the original building is now standing. Hatfield is the seat of a poor-law union embracing four parishes. The population of parish in 1871 was 3998. In the vicinity is Hatfield House, on the site of a palace of the bishops of Ely, which was erected about the beginning of the 12th century. In 1538 the manor was resigned to Henry VIII. by Bishop Goodrich, in exchange for certain lands in Cambridge, Essex, and Norfolk; and after that monarch the palace was successively the residence of Edward VI. immediately before his accession, of Queen Elizabeth during the reign of her sister Mary, and of James I. The last-named exchanged it in 1607 for Theobalds, near Cheshunt, in the same county, an estate of Sir Robert Cecil, afterwards earl of Salisbury, in whose family Hatfield House has since remained. The west wing of the present mansion, built for Cecil in 1608-11, was destroyed by fire in November 1835, the dowager-marchioness of Salisbury perishing in the flames. The grounds surrounding the house are extensive and beautifully laid out.

HATHRAS, or **HATRAS**, a town in the Aligarh district, North-Western Provinces, India, in 27° 35' 31" N. lat., 78° 6' 9" E. long. It is well built, with numerous brick and stone houses, and is a prosperous trading centre. At the end of last century it was held by the Ját TLákur, Dáya Rám, whose ruined fort still stands at the east end of the town, and was annexed by the British in 1803. A municipal hall and school-house stand upon the brink of a new tank; and the town also contains a post-office and Government charitable dispensary. Since it came under British rule, Háthras has rapidly risen to commercial importance, and now ranks second to Cawnpore among the trading centres of the Doáb. The exports include coarse sugar, grain of all sorts, oil-seeds, cotton, and *ghí*; and the imports embrace iron, metal vessels, European and native cloth, drugs, spices, and miscellaneous wares. Population (1872), 23,589, comprising 21,121 Hindus and 2468 Mahometans.

HATTINGEN, a town of Westphalia, Prussia, in the government district of Arnsberg and the circle of Bochum, is situated on the river Ruhr, about 21 miles N.E. of Düsseldorf. It is the seat of a commission of justice, and possesses a good school. The manufactures comprise cloth.

woollen and silk goods, tobacco, iron, and steel. In the town are large iron-works, a brewery, and a brandy distillery. There are iron-stone and coal mines in the neighbourhood, and the scanty remains of the Isenburg, demolished in 1226. Hattingen was one of the Hanse towns of the Middle Ages. Its population in 1875 was 6995.

HATTO I. (c. 850-913), tenth archbishop of Mainz, was born of a Swabian family about the middle of the 9th century. Educated at the monastery of Ellwangen or at Fulda, he attracted the attention of the emperor Arnulf, who in 883 made him abbot of Reichenau, in 889 abbot of Ellwangen, and in 891 archbishop of Mainz. During his reign Hatto acquired much ecclesiastical as well as political power. He presided over the council at Tribur or Teuver (895), at which the emperor and twenty-six or twenty-seven bishops attended, and was employed as ambassador to Charles the Simple and the king of Lorraine at their conference at Saint Goar in 899. Twice he accompanied Arnulf to Italy, in 894 and 896. On the death of Arnulf in 900, Hatto became regent and guardian of Louis, and in the contest with the dukes of Babenberg treacherously betrayed into the emperor's hands Count Adalbert, who was one of their partisans. Under Louis's successor, Conrad I., Hatto retained his influence, but he died in 913, two years after Conrad's accession. Another but less probable account has it that he was killed at the battle of Heresburg in 912. Hatto was a zealous churchman and a bold and energetic statesman. By his influence the crown and the church combined to check the growing power of the great nobles. In a letter to Pope John IX., still extant, he defends the German bishops from certain charges made to the pope. There is a tradition, due probably to his ambition and violence, that his corpse was seized by the devil and thrown into the crater of Mount Etna. The tradition of the Mouse Tower, on the Rhine at Bingen is connected with another Hatto, also archbishop of Mainz (968-970).

HATVAN, a market-town in the county of Heves, Hungary, is situated on the left bank of the Zagyva, at the junction of the Pest-Miskolcz, Hatvan-Rutka, and Hatvan-Szolnok lines of railway, about 30 miles E.N.E. of Budapest, 47° 40' N. lat., 19° 41' E. long. Hatvan possesses a handsome church and an elegant castle. There are two large cloth factories, and a court of assize is held there. Many of the inhabitants of the town and neighbourhood are employed in raising fruit and melons, in improving the breed of sheep and in tending large herds of horses, which graze wild on the spacious communal pasture-lands. Cattle fairs are frequently held in the town, and the trade in horses is considerable. In 1870 the population amounted to 4018, for the most part Magyars by nationality and Roman Catholics by creed.

As a fortified place Hatvan rose to some importance in the Middle Ages. In July 1525 a diet of Magyar nobles was held there. Subsequent to the catastrophe at Mohács (1526), Hatvan, along with many other Hungarian towns, fell into the hands of the Turks. After being besieged by the imperialists in 1594 and 1595, it was taken by them on the 3d September 1596. In 1678 it was almost completely destroyed by the Ottoman forces. On the 2d April 1849 the Austrians were defeated by the Hungarians in a sanguinary engagement near the town.

HATZFELD (Hungarian, *Zsombolya*), a market-town in the county of Torontál, Hungary, on the Austrian state line of railway, about 22 miles W. of Temesvár, 45° 48' N. lat., 20° 44' E. long. The most important buildings are the Roman Catholic church, the château of Count Csekonic, a district court-house, and the usual Government offices. The communal lands are large and very productive, more especially in wheat, barley, oats, Indian corn, and rape seed. The rearing of horses is extensively carried on. In 1870 the population amounted to 7981, for the most part Germans by nationality and Roman Catholics by creed.

HAUCH, JOHANNES CARSTEN (1790-1872), Danish poet, was born of Danish parents residing at Frederikshald in Norway, on the 12th of May 1790. In 1802 he lost his mother, and in 1803 returned with his father to Denmark. In 1807 he fought as a volunteer against the English invasion. He entered the university of Copenhagen in 1808, and in 1821 took his doctor's degree. He became the friend and associate of Steffens and Oehlenschläger, warmly adopting the new views about poetry and philosophy. His first dramas, *The Journey to Givistan* and *The Power of Fancy*, appeared in 1816 and 1817, and were followed by *Flosaura*; but these works attracted little or no attention. Hauch therefore gave up all hope of fame as a poet, and resigned himself entirely to the study of science, to pursue which he went abroad. At Nice he had an accident which obliged him to submit to the amputation of one foot. He returned to dramatic production, and published *The Hamadryad*, *Bajazet*, *Tiberius*, *Gregory VII.*, *The Death of Charles V.* (1831), and *The Siege of Maastricht* (1832). These plays were violently attacked by the best critical organs, and enjoyed no success. Hauch then turned to novel-writing, and published in succession four romances—*Vilhelm Zabern*, 1834; *Guldmageren*, 1836; *A Polish Family*, 1829; and *The Castle on the Rhine*, 1845. In 1842 he collected his shorter *Poems*. In 1846 he was appointed professor of the Scandinavian languages in Kiel, but returned to Copenhagen when the war broke out in 1848. About this time his dramatic talent was at its height, and he produced one admirable tragedy after another; among these may be mentioned *Svend Grathe*, 1841; *The Sisters at Kinnekullen*, 1849; *Marsk Stig*, 1850; *Honour Lost and Won*, 1851; and *Tycho Brahe's Youth*, 1852. From 1858 to 1860 Hauch was director of the Danish National Theatre; he produced three more tragedies—*The King's Favourite*, 1859; *Henry of Navarre*, 1863; and *Julian the Apostate*, 1868. In 1861 he published another collection of *Poems*, and in 1862 the historical epic of *Valdemar Atterdag*. From 1851, when he succeeded Oehlenschläger, to his death, he held the honorary post of professor of æsthetics at the university of Copenhagen. He died in Rome in 1872. Hauch was one of the most prolific of the Danish poets, and his writings are unequal in value. His lyrics and romances in verse are always fine in form and often strongly imaginative. In all his writings, but especially in his tragedies, he displays a strong bias in favour of what is mystical and supernatural. Of his dramas *Marsk Stig* is perhaps the best, and of his novels *Vilhelm Zabern* is admired the most.

HAUFF, WILHELM (1802-1827), a popular German novelist, was born at Stuttgart, 29th November 1802. Having lost his father, who was a Government official, at the age of seven, he repaired with his mother to Tübingen, where he frequented the *Schola anatolica*. In 1818 he was sent to the *Klosterschule* at Blaubeuren, and two years later he entered the seminary of Tübingen. After having completed, in 1824, his philosophical and theological studies and taken his degree, he acted for two years as private tutor, and assumed, in January 1827, the editorship of the *Morgenblatt*. In the following month he married, and led a happy and quiet life, which was ended by a fatal illness on 18th November of the same year. Hauff's literary activity is comprised within the short space of about two years. In his *Märchenatmanach* for 1826 he published the *Fairy Tales* he used to relate to his pupils during his tutorship. They were distinguished by an originality of conception, a playful though somewhat fantastic humour, and an elegance of style, not usually met with in similar productions. Those fanciful tales founded his fame as a narrator, and form, together with his subsequent novels, several of which belong to the same species, the basis of his per-

manent reputation as an author. His next publication, *Mittheilungen aus den Memoiren des Satans*, "Extracts from the Memoirs of Satan" (2 vols. 1826-27), was of a fragmentary kind, but gave additional proof of his talent as a humorist. In 1826 he wrote a novel—*Der Mann im Monde*, "The Man in the Moon"—with the intention of satirizing and parodying the sentimental sensualism of Claubern; but in the course of composition the projected parody became a regular imitation, and, as he issued the novel under the name of that romancer, the latter brought an action against him for the abuse of his name, and gained his lawsuit. Hauff succeeded, however, in morally annihilating that maudlin narrator by his witty *Controverspredigt*, "Controversial Sermon" (1826). Animated by the genius of Sir Walter Scott, Hauff wrote a historical romance called *Lichtenstein* (1826), which illustrated the most interesting period in the history of Württemberg, and, being one of the first historical German novels, acquired, in spite of its weakness as a literary composition, great popularity throughout Germany. His fanciful work, *Phantasien im Breiter Rathskeller* (1827), is pervaded, especially in the first portion of the book, by an exuberant spirit of conviviality, which exercises a cheering effect on the reader; but his most perfect fiction is the *Bettlerin vom Pent-des-Arts*. Hauff's works have gone, collectively and separately, through many editions, and some of his shorter poems have become regular "Volkslieder."

HAUG, JOHANN CHRISTOPH FRIEDRICH (1761-1829), a German epigrammatist, was born March 19, 1761, at Niederstotzingen in Württemberg, and received his early training from his father, who was afterwards professor and preacher at Stuttgart. From the gymnasium in this city Haug passed in 1776 to the Prince Charles academy, where he had Schiller as a fellow scholar, and, after finishing the philosophical and philological course, he devoted himself to the study of legal science with so much success that he attracted the attention of the duke. In 1784 he was appointed secretary of the private closet to his patron, in 1791 received the title of curial and palatine count, in 1794 became the duke's private secretary, and in 1817 was made *Hofrath* or aulic councillor and librarian of the public library at Stuttgart. In 1827 he travelled through northern Germany, and on 30th January 1829 he died. Haug began his career as an author by publishing *Sinngedichte von Friedrich Hophthalmos* (Frankfort, 1791), the pseudonym Hophthalmos being a jocular Greek equivalent of his own name (*Aug*, the eye, equal to *Ophthalmos*, and therefore Haug equal to Hophthalmos).

Among his later works, which are as often characterized by a love of fun as by power of wit, it is enough to mention *Epigramme und vermischte Gedichte*, Berlin, 1805; *Hundert Epigramme auf Aerzte die Keine sind*, Zurich, 1806; *Epigrammatische Spiele*, 1807; *Taschenbuch dem Bacchus und Iocus geweiht*, Stuttgart, n.d.; *Magische Laterne*, Brünn, 1820; *Panorama der Laune und des Witzes*, Tübingen, 1826; and, perhaps more famous than any, *Zweihundert Hyperbeln auf Herrn Wahls ungeheure Nase*, Stuttgart, 1804, new edition, Brünn, 1822. Along with Weisses, Haug published *Epigrammatische Anthologie*, Stuttgart, 1807-1809, 10 vols. A selection from his poems appeared at Hamburg, 1827, 2 vols.

HAUG, MARTIN (1827-1876), Orientalist, was born at Ostdorf near Balingen, Württemberg, January 30, 1827. As a self-taught lad he became a pupil in the gymnasium at Stuttgart at a comparatively late age; and in 1848 he entered the university of Tübingen, where he devoted himself to the study of the Oriental languages, and especially of Sanskrit under Roth. He afterwards for some time attended the lectures of Ewald and Benfey in Göttingen, and finally "habilitated" as a privat-docent at Bonn. In 1856 he removed to Heidelberg as collaborateur in the preparation of Bunsen's *Bibelwerk*; and in 1859 he accepted an invitation to India, where he became superintendent of Sanskrit studies and professor of Sanskrit in Poona. There

his previous acquaintance with the Zend language and literature enabled him to associate with the Parsees on such terms as afforded the best opportunities for perfecting his knowledge in this department. The result of his researches was the volume of *Essays on the Sacred Language, Writings, and Religion of the Parsees* (Bombay, 1862). After a residence of six years in India, he was compelled by domestic circumstances to return to Würtemberg in 1865; from Stuttgart he was called to Munich as first professor ordinarius of Sanskrit and comparative grammar in 1868. He died at Ragatz in Switzerland on the 3d of June 1876.

Besides the *Essays on the Parsees*, of which a new edition, by West, greatly enriched from the posthumous papers of the author, appeared in 1878, Haug published a number of works of considerable importance to the student of the literatures of ancient India and Persia. They include *Die Pehlevisprache u. der Bundehesch* (1854); *Die Schrift u. Sprache der zweiten Keilschriftgattung* (1855); *Die fünf Gathas*, edited, translated, and expounded (1858-60); an edition with translation and explanation of *The Aitareya Brahmana of the Rigveda* (1863); *A Lecture on an original Speech of Zoroaster* (1865); *An old Zend-Pahlavi Glossary* (1867); *Ueber den Charakter der Pehlevisprache* (1869); *Das 18te Capitel des Wendidad* (1869); *Ueber das Arda-Viraf-nameh* (1870); *An old Pahlavi-Pazand Glossary* (1870); *Vedische Räthselfragen u. Räthselprüche* (1875).

HAUGE, HANS NIELSEN (1771-1824), founder of a religious sect within the Lutheran Church of Norway and Denmark, was born in the former country, in the parish of Thunö, April 3, 1771. With the aid of various religious works which he found in his father's house, he laboured to supplement the scanty education which he had received as a peasant's son. In his twenty-sixth year, believing himself divinely commissioned, he began to preach in his native parish and afterwards throughout Norway. In 1800 he passed to Denmark, where, as at home, he gained many followers and assistants, chiefly among the lower orders. Proceeding to Christiansand in 1804, Hauge set up a printing-press to disseminate his views more widely, but was almost immediately arrested for holding illegal religious meetings, and for insulting the regular clergy in his books, all of which were confiscated. After being in confinement for ten years, he was released in 1814 on payment of a fine, and retiring to an estate at Breddwill, near Christiania, he died there, March 29, 1824. His adherents, called *Haugianer* or *Leser* (i.e., Readers), are still to be found in the south of Norway. By his writing and preaching he unquestionably did much to revive the spiritual life of the northern Lutheran Church. Though he cannot be said to have rejected any article of the Lutheran creed, the peculiar emphasis which he laid upon the evangelical doctrines of faith and grace involved considerable antagonism to the rationalistic or sacerdotal views commonly held by the established clergy.

Hauge's principal writings are *Forstg til Afhandling om Guds Visdom*, 1796; *Anvisning til nogle mørkelige Sprog i Bibelen*, 1798; *Forklaring over Loven og Evangelium*, 1803. For an account of his life and doctrines, see Chr. Bang's *Hans Nielsen Hauge og hans Samtid*, Christiania, 1875.

HAUPT, MORITZ or MORIZ (1808-1874), one of the principal representatives at once of classical and of vernacular philology in Germany, was born at Zittau, in Lusatia, July 27, 1808. His early education was mainly conducted by his father, Ernst Friedrich Haupt, burgomaster of Zittau, a man of good scholarly attainment, who used to take pleasure in turning German hymns or Goethe's poems into Latin, and whose memoranda have been employed by Freytag in the 4th volume of his *Bilder aus der deutschen Vergangenheit*. From the Zittau gymnasium, where he spent the five years 1821-1826, partly under the tuition of Lindemann, Haupt removed to the university of Leipsic with the intention of prosecuting theology; but the natural bent of his mind and the influence of Professor G. Hermann soon turned all his energies in the direction of what were to be his life-studies. On the close of his university course

(1830) he returned to his father's house, and the next seven years were devoted to quiet work not only at Greek, Latin, and German, but at Old French, Provençal, and Bohemian. In 1834 he became acquainted with Endlicher, Karajan, and F. Wolf at Vienna, and formed with Lachmann at Berlin a friendship which had great effect on his intellectual development. In September 1837 he "habilitated" at Leipsic as privat-docent, and his first lectures, dealing with such diverse subjects as Catullus and the Nibelungenlied, indicated the twofold direction of his labours. A new chair of German language and literature being founded in his behoof, the new teacher received in succession the title of professor extraordinarius (September 1841) and professor ordinarius (November 1843); and in 1842 he married Louise Hermann, the daughter of his master and colleague. But the peaceful and prosperous course opening out before him at the university of Leipsic was brought to a sudden close. Having taken part in 1849 with Otto Jahn and Theodor Mommsen in a political agitation for the maintenance of the imperial constitution, Haupt was deprived of his professorship by a decree of the 22d April 1851. Two years later, however, he was called to succeed Lachmann at the university of Berlin; and at the same time the Berlin academy, which had made him a corresponding member in 1841, elected him an ordinary member. For one and twenty years he continued to hold a prominent place among the scholars of the Prussian capital, making his presence felt, not only by the prestige of his erudition and the clearness of his intellect, but by the tirelessness of his energy and the ardent fearlessness of his temperament. His death, which took place with very little warning, February 5, 1874, was the result of heart disease.

Haupt's critical work is distinguished by a happy union of the most painstaking investigation with intrepidity of conjecture, and while in his lectures and addresses he was frequently carried away by the excitement of the moment, and made sharp and questionable attacks on his opponents, in his writings he exhibits great self-control. The results of many of his researches are altogether lost, because he could not be prevailed upon to publish what fell much short of his own high ideal of excellence. To the progress of classical scholarship he contributed by *Questiones Catullianæ* (1837), *Observationes Criticæ* (1841), and editions of Ovid's *Halieutica* and the *Cynegetica* of Grattius and Nemesianus (1838), of Catullus, Tibullus, and Propertius (3d ed., 1868), of Horace (3d ed., 1871); and of Virgil (2d ed., 1873). As early as 1836 he with Hoffmann von Fallersleben started the *Alteutsche Blätter*, which in 1841 gave place to the *Zeitschrift für deutsches Alterthum*, of which he continued editor till his death. Hartmann von Aue's *Ercc* (1839) and his *Lieder*, *Büchlein*, and *Der arme Heinrich* (1842), Rudolf von Ems's *Guler Gerhard* (1840), and Conrad von Würzburg's *Engelhard* (1844) are the principal German works which he edited. To form a collection of the French songs of the 16th century was one of his favourite schemes, but a little volume published since his death, *Französische Volkslieder* (1877), is the only monument of his labours in that direction. Three volumes of his *Opuscula* have appeared (Leipsic, 1875-1877). See Kirchhoff, "Gedächtnissrede," in *Abhandl. der Königl. Akad. der Wissenschaften zu Berlin*, 1875; and Otto Belger, *Moriz Haupt als Lehrer*, 1879.

HAUPTMANN, MORITZ (1792-1868), although a composer of ability, was of infinitely greater importance as a writer on the theory of music. He was born at Dresden, October 13, 1792, and studied music under Scholz, Lanska, Grosse, and Morlacchi, the rival of Weber. Afterwards he completed his education as a violinist and composer under Spohr, and till 1820 held various appointments in private families, varying his musical occupations with mathematical and other studies bearing chiefly on acoustics and kindred subjects. For a time also Hauptmann was employed as an architect, but all other pursuits gave place to music, and a grand tragic opera, *Mathilde*, belongs to the period just referred to. In 1822 he entered the orchestra of Cassel, again under Spohr's direction, and it was then that he first taught composition and musical theory to such men as Ferdinand David, Burgmüller, Kiel, and others. His compositions at this

time chiefly consisted of motets, masses, cantatas, and songs. His opera *Mathilde* was performed at Cassel with great success. In 1842 Hauptmann obtained the position of cantor at the Thomas-school of Leipsic (long previously occupied by the great Johann Sebastian Bach) together with that of professor at the conservatoire, and it was in this capacity that his unique gift as a teacher developed itself and was acknowledged by a crowd of enthusiastic and more or less distinguished pupils. He died on January 3, 1868, and the universal regret felt at his death at Leipsic is said to have been all but equal to that caused by the loss of his friend Mendelssohn many years before. Hauptmann's compositions are marked by symmetry and perfection of workmanship rather than by spontaneous invention.

Amongst his vocal compositions—by far the most important portion of his work—may be mentioned two masses, choral songs for mixed voices (*Op.* 32, 47), and numerous part songs. The results of his scientific research were embodied in his book *Die Natur der Harmonik und Metrik* (1853), a standard work of its kind, in which a philosophic explanation of the forms of music is attempted.

HAURAN. See BASHAN.

HAUSER, KASPAR, a German youth whose life was remarkable from the circumstances of apparently inexplicable mystery in which it was involved. He appeared on May 20, 1828, in the streets of Nuremberg, dressed in the garb of a peasant, and with such a helpless and bewildered air that he attracted the attention of the passers-by. In his possession, was found a letter purporting to be written by a poor labourer, stating that the boy was given into his custody on the 7th October 1812, and that according to agreement he had instructed him in reading, writing, and the Christian religion, but that up to the time fixed for relinquishing his custody he had kept him in close confinement. Along with this letter was enclosed another purporting to be written by the boy's mother, stating that he was born on the 30th April 1812, that his name was Kaspar, and that his father, formerly a cavalry officer in the 6th regiment at Nuremberg, was dead. The appearance, bearing, and professions of the youth corresponded closely with these credentials. He showed a repugnance to all nourishment except bread and water, was seemingly ignorant of outward objects, wrote his name as Kaspar Hauser, and said that he wished to be a cavalry officer like his father. For some time he was detained in prison at Nuremberg as a vagrant, but on July 18, 1828, he was delivered over to the care of Professor Daumer, who undertook to be his guardian and to take the charge of his education. On October 17, 1829, he was found to have received a wound in the forehead, which according to his own statement had been inflicted on him by a man with a blackened face. Having on this account been removed to the house of a magistrate and placed under close surveillance, he was visited by Earl Stanhope, who became so interested in his history that he sent him to Ausbach to be educated. After this he became clerk in the office of Feuerbach, president of the court of appeal, and his strange history was almost forgotten by the public when the interest in it was suddenly revived by his death on the 14th December 1833 from a deep wound on his left breast. He affirmed that the wound was inflicted by a stranger, but many believed it to be the work of his own hand, and that he did not intend it to be fatal, but only so severe as to give a sufficient colouring of truth to his story.

In 1830 a pamphlet was published at Berlin, entitled *Kaspar Hauser nicht unwahrscheinlich ein Betrüger*; but the truthfulness of his statements was defended by Daumer, who published *Mittheilungen über Kaspar Hauser* (Nuremberg, 1832), and *Erhellungen über Kaspar Hauser* (Frankfort, 1859); as well as *Kaspar Hauser, sein Wesen, seine Unschuld*, &c. (Regensburg, 1873), in answer to Meyer's *Authentische Mittheilungen über Kaspar Hauser* (Ausbach, 1872). Feuerbach awakened considerable psychological interest in

the case by his pamphlet *Kaspar Hauser, Beispiel eines Verbrechens am Seelenleben* (Ausbach, 1832), and Earl Stanhope also took part in the discussion by publishing *Materialien zur Geschichte K. Hausers* (Heidelberg, 1836). The theory of Daumer and Feuerbach was that the youth was the son of the grand-duke Charles of Baden, and that he had been kidnapped by the countess of Hochberg in order to secure the succession to the children of the grand-duke Charles Frederick; but this theory was set aside in 1875 by the publication in the Augsburg *Allgemeine Zeitung* of the official record of the baptism, post-mortem examination, and burial of the heir supposed to have been kidnapped. See *Kaspar Hauser und sein badisches Prinzenenthum* (Heidelberg, 1876).

HAÛY, RENÉ JUST (1743-1822), an eminent French mineralogist, commonly styled the Abbé Haüy, from being an honorary canon of Notre Dame, was born at St Just, in the department of Oise, February 28, 1743. His parents were in a humble rank of life, and were only enabled by the kindness of friends to educate their son. He was sent to Paris to the college of Navarre, and afterwards to that of Lemoine, where he finished his course amid incredible privations and difficulties. He escaped from these when, in 1764, he was himself appointed one of the teachers in the first of the above-named colleges. He began to devote his leisure hours to the study of botany; but an accident directed his attention to another field in natural history. Happening to let fall a beautiful specimen of calcareous spar belonging to a friend, he discovered, by examining the fragments, the geometrical law of crystallization. By experimenting on a hexahedral crystal of this substance, he found that it could be so dissected, by dividing it by planes parallel to certain edges, as to exhibit a rhombohedral nucleus, and, by extending his experiments, he farther showed that the same result could be obtained from mechanical division of every crystal of the same species. This led him to the theory that crystals are composed of what he called "integrant molecules," which he held had each the same shape as the respective nuclei got at by mechanical division. To obtain the different crystalline forms these molecules were supposed to be built up in layers round the nucleus, each layer diminishing regularly in the number of rows of molecules, and the rows at the same time diminishing in the number of molecules according to the nature of the crystal. A full account of his mathematical theory of this subject is given by Haüy in his *Traité de Minéralogie* (see CRYSTALLOGRAPHY). Daubenton and Laplace immediately recognized the scientific value of the discovery, which, when communicated to the Academy, secured for its author a place in that society. Besides the important service which he rendered to crystallography, Haüy also greatly increased our knowledge of pyro-electricity. He demonstrated by experiment in the case of tourmaline that the positive and negative charges of electricity at the respective ends of the crystal diminish rapidly as we approach the middle point, where they disappear. He showed also that each particle of a broken pyro-electric crystal itself exhibits polarity; and he was likewise the first to observe that, in all minerals, the pyro-electric state has an important connexion with the want of symmetry of the crystals. In tourmaline, for instance, he found the vitreous charge always at the summit with six, and the resinous at the summit with three faces (see ELECTRICITY). When the Revolution broke out, Haüy was thrown into prison, and his life was even in danger, when he was saved by the intercession of Geoffroy Saint-Hilaire. Under Napoleon he became professor of mineralogy at the museum of natural history. He also obtained other scientific preferment, of which he was deprived by the feeble Government of the Restoration, though his royalism had been a serious bar to his promotion under the empire. His latter days were consequently clouded by the poverty which had threatened to blight his early career. But the courage and high moral qualities which had helped him forward in his youth did

not desert him in his old age; and he lived cheerful and respected till his death, June 3, 1822.

The following are his principal works:—*Essai d'une Théorie sur la Structure des Cristaux*, 1784; *Exposition raisonnée de la Théorie de l'Électricité et du Magnétisme, d'après les Principes d'Épinus*, 1787; *De la Structure considérée comme Caractère Distinctif des Minéraux*, 1793; *Exposition abrégée de la Théorie de la Structure des Cristaux*, 1793; *Extrait d'un Traité Élémentaire de Minéralogie*, 1797; *Traité de Minéralogie*, 1802, 4 vols., 2d ed.; *Traité Élémentaire de Physique*, 1803, 1806, 2 vols.; *Tableau Comparatif des Résultats de la Cristallographie, et de l'Analyse Chimique relativement à la Classification des Minéraux*; *Traité des Pierres Précieuses*, 1817; *Traité de Cristallographie*, 1822, 2 vols. He also contributed papers to various scientific journals, particularly the *Journal d'Histoire Naturelle*, *Annales de Chimie*, *Journal de Physique*, *Magasin Encyclopédique*, *Annales du Muséum d'Histoire Naturelle*, and *Journal des Mines*.

HAVANA, HAVANNAH, or HABANA, more fully San Cristobal de la Havana, the capital of Cuba, and one of the principal seats of commerce in the New World, is situated on the northern coast of the island in 23° 9' 24" N. lat. and 82° 22' 35" W. long. From the sea it presents a picturesque appearance. The background is indeed tame; but the long lines of fortifications, the church-towers, and the shipping relieve the somewhat tawdry effect of the gaily coloured houses. Though the walls, completed in 1702, have been almost entirely demolished since 1863, it is still usual to speak of the intramural and the extramural city. The former, lying close to the harbour, has streets of the narrowest possible description consistent with the existence of wheel traffic. The latter has been laid out on a spacious plan, with wide thoroughfares frequently fringed with trees. Most of the houses are built of solid stone and have flat roofs, after the manner in vogue in southern Spain, and, as the erection of wooden buildings has been illegal since 1772, it is only in the suburban districts that they are at all common. The lavish use of white marble in the decoration both of shops and dwelling-houses is one of the peculiarities of the popular taste; and it is worthy of remark that, though the native quarries would supply what is wanted, the marble is brought from Genoa. Cafés, restaurants, clubs, and casinos are both exceedingly numerous and largely frequented, forming a good indication of that general absence of domestic life among the white population which surprises the European visitant. Havana is still, as of yore, a city of smells and noises. There is no satisfactory cleaning of the streets or draining of the sub-soil, and the harbour is visibly rendered foul by the impurities of the town. Victorias,—of which it is the Cuban boast that there are 6000,—volantes, and other vehicles are driven through the thoroughfares with the utmost recklessness; and tramways and railways in the American fashion contribute to the confusion.

The principal defences of Havana are the Castillo de la Punta, to the west of the harbour entrance, the Castillo del Morro and San Carlos de la Cabaña to the east, the Santo Domingo de Atares, which lies at the head of the western arm of the bay and commands both the city and the neighbourhood, and the Castillo del Principe, situated on an eminence to the west, and forming the terminus of the great Paseo Militar. El Morro, as it is popularly called, was first erected in 1589, but additions have been frequently made. La Punta, a much smaller fort, is of the same period. The castle of Atares dates from about 1763, when the Conde de Riela was governor of the island. Cabaña, which alone has accommodation for 4000 men, fronts the bay for a distance of 800 yards, and is defended on the land side by three bastions. To the east there lies a smaller fort, No. 4, or San Diego, on a hill about 100 feet high.

Of the churches in the city, which number more than a score, the most noteworthy is the cathedral erected in 1724 by the Jesuits. Externally it is plain though symmetrical; but within it has richly frescoed walls, a floor of variegated

marble, and costly altars. In the wall of the chancel, a second-rate medallion and a sordid inscription distinguish the tomb of Columbus, whose remains were removed thither in 1796. It is enough to mention the churches of San Juan de Dios, dating from 1573, Santa Catalina (1658), San Agostino (1608), and San Felipe, which possesses a large library. Of monasteries and nunneries there is of course no lack; and the same may be said of charitable institutions. The most important of the seven hospitals is the Real Casa de Beneficencia, founded about 1790, and containing an orphan asylum, a home for vagrants, a lunatic asylum, and an infirmary.

Besides the university established in 1728, the city possesses a theological seminary, a military school, and a school of art. The governor and the bishop have their respective palaces, the former a large yellow stone building in the Plaza de Armas; a large prison, erected in 1771, capable of receiving 500 inmates, and with barracks for a regiment, forms a striking object in the general view of the city; and among the other public buildings are the exchange (El Muelle), the custom-house (formerly the

Plan of Havana.

church of San Francisco), and the maestranza or headquarters of the artillery. Of the theatres, which have still to compete with the bull-ring and the cock-pit, the most important is the Tacon, erected in 1838, and capable of accommodating about 3000 persons. The promenades, drives, and public gardens form a notable feature of Havana: it is sufficient to mention the Plaza de Armas, with a statue of Ferdinand VII.; the Prado or Paseo Isabel, a long and handsome boulevard laid out in the 18th century; the Campo del Marta or drill-park; the Parque Isabel, the Paseo Tacon, the botanical gardens, and the gardens of Los Molinos, the suburban residence of the captain-general. The palm-tree avenues of Los Molinos are unusually fine. Along the borders of the bay there are several fine embankments, of which the best is perhaps that called either the Salon O'Donnell or the Alamada de Paula. In the coral rock of the coast sea-baths have been excavated, so that the bathers may run no risk from the shark; each apartment is about 12 feet square and 6 or 8 feet deep, and the water enters by two port-holes. The city is supplied with water from the river Chorrera by an aqueduct (Canal Isabel II.) constructed by Antonelli under Philip II., and

the number of fountains is considerable. The markets—of which the most noteworthy are the Mercado de Cristina, erected in 1836, and the Mercado de Tacon or Plaza de Vapor—are abundantly stocked with fruits and vegetables. Several of the suburban villages (*e.g.*, Chorrera, Guanabacón) are attractive places of resort.

The bay of Havana makes one of the finest harbours in the world, easy of access, spacious enough to contain about 1000 large vessels, deep enough to allow them to come close up to the wharves, and, except in the case of a hurricane, well protected on all sides. The entrance, encumbered by neither bar nor rock, is 980 feet wide and 4200 feet long. Within, the bay breaks up into three distinct arms, named respectively Marimaleña or Regla Bay, Guasabacoa Bay, and El Fondo or Bay of Atares. The wharves are well built, and a good floating dock is maintained by a private company. On the left hand of the entrance stands a lofty lighthouse tower.

In 1865 1950 vessels entered with a burthen of 686,644 tons; in 1873 2194 vessels with a burthen of 921,632 tons; and in the first six months of 1878 741 vessels with a burthen of 449,785 tons. The average number of vessels annually in the ten years from 1864 to 1873 was 1981 (771,196 tons), and of this average 647 (324,373 tons) were American, 689 (190,231 tons) Spanish, 384 (131,216 tons) British, 55 (46,213 tons) French, 55 (18,200 tons) Norwegian, and 32 (31,693 tons) German.

In spite of high tariffs and civil wars, and the competition of Matanzas, Cardenas, Cienfuego, and other Cuban ports opened to foreign trade in modern times, the commerce of Havana continues to increase. As indicated by the statistics just quoted, the chief foreign customers are Britain and the United States; but, while the latter are gradually taking a greater proportion of the trade, the British interest is gradually diminishing. The two staple articles of export are sugar and tobacco-wares. While the average export of sugar for the first ten years of the century was only 177,998 boxes (61,199,200 lb), by 1855 it had reached 966,677 boxes (386,270,800 lb), and by 1873 145,601 boxes, 102,786 hogsheads, and 91,974 tons, or a grand total of nearly 408 millions of lb. In 1867 there were exported 7,716,802 lb of tobacco and 199,027 millions of cigars, and the corresponding numbers for 1878 were 13,864,800 lb and 174,633 millions. Other exports of importance are rum, wax, and honey. The nature and quantities of the imports on an average of the ten years 1868 to 1877 are 295,202 quintals (100 lb each) of jerked beef, 134,203 quintals of cod-fish (61,576 from Europe, and 41,019 from United States), 359,925 barrels of flour, 627,786 quintals of rice (mainly from the East Indies), 143,035 quintals of lard (from the United States), 85,503 pipes of wine, 145,539 tons of coal, 344,095 jars of olive oil, and 92,857 quintals of coal-oil.

The staple manufacturing industry of Havana is that of tobacco. Of the cigar factories, more than a hundred may be reckoned as of the first class. The Royal and Imperial Factory of La Honradez, which occupies a whole square, and is considered one of the great sights of the city, produces daily 2,532,000 cigarettes. Besides the making of boxes and barrels, and other articles necessarily involved in its sugar and tobacco trade, Havana also prosecutes to some extent the building of carriages and ships, and the manufacture of iron and machinery; but the weight of taxation is too great to allow the development of any business requiring great capital. There were six banks in the city in 1877, the most important being the Spanish Bank, through which all the Government paper is issued.

Havana has steam communication several times a week with New York; once a week with Baltimore, Philadelphia, and New Orleans; and about as frequently with several ports in England, Spain, and France. It is the terminus of a railway system which reaches Cardenas, Cienfuego, Matanzas, Batabano, &c.; and short lines run out to the Bay of Havana and Marianas. Telegraphs radiate to all parts of the island; and a submarine cable to Key West forms part of the line of communication between Aspinwall and New York.

The population of Havana and its suburbs was stated at 139,996 in 1817, at 196,994 in 1841, at 203,676 in 1863, and at 169,184 in 1871. Of this last number 108,764 were whites, 27,623 free negroes, mulattos, &c., and 22,807 slaves. By 1873 the total had reached, it is said, 230,000. None of these statistics can be received with much confidence as to their accuracy. Among the white population the proportion of males to females is extraordinarily high: according to the official returns, there die annually 3682 white males to 1204 white females. The average rate of mortality is 27 per thousand annually. Foreigners are subject to yellow fever, especially from June to September.

Havana, originally founded by Diego Velasquez in 1515 on an unhealthy site near the present harbour of Baracon on the south coast, was removed to its actual position about 1519, and soon began to be

considered one of the most important places in the New World. In 1528 the buccaneers laid the settlement in ashes, but it was soon after restored by Da Soto, who built the fortress of La Fuerza. The residence of the captain-general was transferred to Havana from Santiago de Cuba in 1551; and in 1589, to protect the city, which had been plundered by the pirate Jacob Sores in 1555 and threatened by Drake in 1585, Philip II. of Spain ordered the erection of the Bateria de la Punta and the castle of El Morro or Los Tres Reyes. In the course of the 17th century the port became the great rendezvous for the gold-ships of Spain, and the commercial centre of the Spanish possessions in America. The English under Admiral Pocock and the duke of Albemarle captured Havana in 1762, but it was restored to the Spaniards on 10th Feb. 1763, in exchange for the Floridas. The *Gaceta de la Habana*, the first paper published in Cuba, appeared in 1782. In 1771 the port, which had formerly been, like the rest of Cuba, monopolized by Seville and Cadiz, was declared open to all nations in regard to certain articles of trade; and this liberty was extended in 1818 to all goods whatsoever. During the despotic-paternal administration of Tacon many improvements were introduced at Havana; the railway from Havana to Guines was commenced in 1835; a ferry between the city and the suburb of Regla was set on foot in 1837; and night watchmen, a police-force, and a fire-brigade were established. The first line of steamships from Cadiz to Havana dates from 1850. Like the rest of Cuba the city has frequently suffered severely from hurricanes, the most violent being those of 1768 (St Theresa's), 1810, and 1846.

See the works referred to under CUBA.

HAVELBERG, an ancient town of Brandenburg, Prussia, in the government district of Potsdam and the circle of Westprieignitz, is situated on the Havel, about 6½ miles from its junction with the Elbe. The nearest station is Glöwen (6¼ miles), on the Berlin and Hamburg Railway. The town is built partly on an island in the Havel and partly on hills on the right bank of the river, on one of which stands the fine cathedral. The two parts, which are connected by a bridge, were incorporated as one town in 1875. Havelberg is the seat of a commission of justice. The inhabitants are chiefly engaged in farming, tobacco and pin manufacturing, sugar-refining, and shipbuilding, and in the timber trade. Population in 1875, 6907.

Otto I. founded a bishopric at Havelberg so early as 946; the bishop, however, generally resided at Plattenburg or Wittstock, a few miles to the north. In 1548 the bishopric was reduced, and the cathedral passed to the Protestant Church and retained its endowments till the edict of 1810, by which all former ecclesiastical possessions were assumed by the crown. The final secularization was delayed till 1819. Havelberg was formerly a strong fortress, but in the Thirty Years' War it was taken from the Danish by the imperial troops in 1627. Recaptured by the Swedes in 1631, and again in 1635 and 1636, it was in 1637 retaken by the Saxons under Klitzeng. It suffered severely from a conflagration in 1870.

HAVELOCK, SIR HENRY (1795–1857), an eminent British soldier, was the second of four brothers (all of whom entered the army), and was born at Ford Hall, Bishop-Wearmouth, Sunderland, on the 5th of April 1795. His parents were William Havelock, a wealthy shipbuilder in Sunderland, and Jane, daughter of John Carter, solicitor at Stockton-on-Tees. When about five years old Henry accompanied his elder brother William to Mr Bradley's school at Swanscombe, whence at the age of ten he removed for seven years to Charterhouse School. In accordance with the desire of his mother, who had died in 1811, he entered the Middle Temple in 1813, studying under Chitty the eminent special pleader. His legal studies having been abridged by a misunderstanding with his father, he in 1815 accepted a second lieutenancy in the Rifle Brigade (95th), procured for him by the interest of his brother William. During the following eight years of service in Britain he read extensively and acquired a good acquaintance with the theory of war. In 1823, having exchanged into the 21st and thence into the 13th Light Infantry, he followed his brothers William and Charles to India, first qualifying himself in Hindustani under Dr Gilchrist, a celebrated Orientalist. At the close of twenty-three years' service he was still a lieutenant, and it was not until 1838 that, after three years' adjutancy of his regiment, he became captain. Before this, however, he had held several staff

appointments, notably that of deputy assistant-adjutant-general of the forces in Burma till the peace of Yandabo, of which he, with Lumsden and Knox, procured the ratifications at Ava from the "Golden Foot," who bestowed on him the "gold leaf" insignia of Burmese nobility. His first command had been at a stockade capture in the war, and he was present also at the battles of Napadee, Patanago, and Paghan. He had also held during his lieutenancy various interpreterships and the adjutancy of the king's troops at Chinsurah. In 1828 he published at Serampore *Campaigns in Ava*, and in 1829 he married Hannah Shepherd, daughter of Dr Marshman, the eminent missionary. About the same time he became a Baptist, being baptized by Mr John Mack at Serampore. During the first Afghan war he was present as aide-de-camp to Sir Willoughby Cotton at the capture of Ghazni, July 29, 1839, and at the occupation of Cabul. After a short absence in Bengal to secure the publication of his *Memoirs of the Afghan Campaign*, he returned to Cabul in charge of recruits, and became interpreter to General Elphinstone. In 1840, being attached to Sir Robert Sale's force, he took part in the Khurd-Cabul fight, in the celebrated passage of the defiles of the Ghilzees (1841), and in the fighting from Tezeen to Jellalabad. Here, after many months' siege, his column in a sortie en masse defeated Akbar Khan, April 7, 1842. He was now made deputy adjutant-general of the infantry division in Cabul, and in September he assisted at Jugdulluk, at Tezeen, and at the release of the British prisoners at Cabul, besides taking a prominent part at Istalif. Having obtained a regimental majority he next went through the Mahratta campaign as Persian interpreter to Sir Hugh (Viscount) Gough, and distinguished himself at Maharajpūr in 1843, and also in the Sikh campaign at Mudki, Ferozeshah, and Sobraon in 1845. For these services he was made deputy adjutant-general at Bombay. He exchanged from the 13th to the 39th, then as second major into the 53d at the beginning of 1849, and soon afterwards left for England, where he spent two years. In 1854 he became quartermaster-general, then full colonel, and lastly adjutant-general of the troops in India. In 1857 he was selected by Sir James Outram for the command of a division in the Persian campaign, during which he was present at the actions of Mohummarah and Ahwaz. Peace with Persia set him free just as the mutiny broke out; and he was chosen to command a column "to quell disturbances in Allahabad, to support Lawrence at Lucknow and Wheeler at Cawnpore, to disperse and utterly destroy all mutineers and insurgents." At Futteh-pūr, July 12th, at Aong and Pandoonudee on the 15th, at Cawnpur on the 16th, at Onao on the 29th, at Buserutgunge on the 29th and again on August 5th, at Boorhiya on August 12th, and at Bithoor on the 16th, he defeated overwhelming forces. Twice he advanced for the relief of Lucknow, but twice prudence forbade a reckless exposure of troops wasted by battle and disease in the almost impracticable task. Reinforcements arriving at last under Outram, he was enabled by the generosity of his superior officer to crown his successes on the 25th of September 1857 by the capture of Lucknow. There he died, November 24, 1857, of dysentery, brought on by the anxieties and fatigues connected with his victorious march, and with the subsequent blockade of the British troops. He lived long enough to receive the intelligence that he had been created K.C.B. for the first three battles of the campaign; but of the major-generalship which was shortly afterwards conferred he never knew. On November 26, before tidings of his death had reached England, letters-patent were directed to create him a baronet, and a pension of £1000 a year was voted at the assembling of parliament. The baronetcy was afterwards bestowed upon

his eldest son; while to his widow, by royal order, was given the rank to which she would have been entitled had her husband survived and been created a baronet. To both widow and son pensions of £1000 were awarded by parliament. See Marshman's *Life of Havelock*, 1860.

HAVERCAMP, SIGEBERT (1683-1742), classical editor and numismatist, was born at Utrecht in December 1683. After studying at the university of his native town and at Leyden, he entered the church, and became minister of Stad-aan-t' Haringvliet, in the island of Overflakkee. There he remained till 1721, when he succeeded Gronovius in the Greek chair at Leyden, becoming shortly afterwards professor of history and rhetoric also. He died at Leyden, April 23, 1742.

His editions of Latin and Greek authors are useful and learned compilations, rather than original critical commentaries, and bear frequent traces of the rapidity with which they were produced. They are the following:—*Tertullian*, 1718; *Lucretius*, 1725; *Josaphus*, 1726; *Eutropius*, 1729; *Orosius*, 1733; *Sallust*, 1742; and *Censorinus*, 1743. See Dibdin's *Classics* under these names. His principal numismatic works are *Dissertationes de Alexandri Magni Numismate*, 1722; *Thesaurus Moretlianus*, 1734; *Universal History, illustrated from Medals* (in Dutch), 1736; *Nummophylacium reginae Christianae*, 1742. He was also the author of *Syllogus Scriptorum qui de lingua Græcæ vera et recta Pronuntiatione commentarios reliquerunt*, 1740; *Introductio in Historiam Patriæ*, 1739; and *Introductio in Antiquitates Romanas*, 1740.

HAVERFORDWEST (in Welsh Hwlfordd), the chief town of Pembrokeshire, a seaport, market-town, parliamentary and municipal borough, and county by itself, is picturesquely situated on a hill overlooking the West Cleddan river, 8 miles N.N.E. of Milford, and 276 miles W.N.W. of London. The town is clean and well built, though somewhat irregular, owing to its position. Its principal buildings are the guildhall and the market-house, both modern, and the church of St Mary, one of the finest churches in South Wales. The old church of St Martin is close to the castle, of which, built on a rocky eminence overhanging the river, only a wall and the keep remain, the latter with considerable additions being till lately used as the county prison. It was built by Gilbert de Clare, first earl of Pembroke; and during the insurrection of Owen Glendower was defended for Henry IV. against the French allies of the Welsh. In the civil wars of the 17th century it was held by the royalists. The castle was visited in 1188 by Giraldus Cambrensis and Archbishop Baldwin. Below the end of the Parade, a public walk overlooking the river, are the ruins of a priory of Black Canons of the order of St Augustine, dedicated to St Mary and St Thomas. Dating from the 12th century it was endowed though not founded by Robert de Hwlfordd, whose liberal grants were confirmed by Edward III. The old wall and fortifications that formerly surrounded the town have totally disappeared. On the north side of the river is the suburb of Prendergast, containing the remains of an ancient mansion, formerly occupied by a family of that name. Haverfordwest is the seat of an assize court and quarter sessions, and with the contributory boroughs of Fishguard and Narberth returns one member to parliament. The river is navigable as high as the bridge for small craft. Timber, tea, and spirits are imported, and coal, cattle, butter, and grain are exported. In 1105, the Flemings, who had been driven from their own country by inundations, were settled in this locality by Henry I., and the Flemings who had served under Stephen afterwards increased the colony. Their influence is still to be traced in the non-use of the Welsh language among the townspeople, and in the peculiar shape of the cottages in the surrounding country. Population in 1871, 6622; area, 1430 acres.

HAVERHILL, a city in Essex county, Massachusetts, United States, is situated on the north bank of the Merrimack river, 18 miles from its mouth, and opposite the towns

of Bradford and Groveland, with which it is connected by two fine bridges. It has railway communication with Boston, which is 32 miles south, and with Portland, 78 miles north. The city contains a handsome soldiers' monument of white marble, erected in 1869, several public halls, including the city hall, the Freemasons' and the Oddfellows' halls, and a public library with 30,000 volumes. Haverhill derives its prosperity from the manufacture of boots and shoes, chiefly of the finer kinds, in which about 150 firms are engaged, employing from 6000 to 8000 hands, and turning out goods to the annual value of about £2,000,000. Besides these there are about forty manufactories of different articles used in this trade, as heels, lasts, shoe-nails, &c. The other manufactures include hats, paper-boxes, and woollen goods. The first settlement at Haverhill was made in 1640, and for 70 years as a frontier town it suffered much from savage attacks. A fine granite and bronze monument has been recently erected to commemorate the heroism of the early settlers. Haverhill was incorporated in 1645, and received its city charter in 1870. The population in 1870 amounted to 13,092, of whom 2003 were foreigners. In 1879 the number was estimated at 15,000.

HAVRE, LE (originally HAVRE DE GRÂCE), a town of France, the second to Marseilles in importance as a seaport, capital of an *arrondissement* in the department of Seine-Inférieure, is situated on the north bank of the estuary of the Seine, 143 miles N.W. of Paris and 55 W. of Rouen by rail. The greater part of the town stands on a level plain, but from the heights on which Ingouville, since 1856 united to Havre, is situated, a charming and varied prospect is obtained. In the lower part of the town the streets run chiefly in straight lines, and they are grouped round the basins or docks, which communicate by lockgates and are placed so as to form a triangle entered from the Outer Port. The old fortifications surrounding the town were demolished in 1856, and it is now defended by forts erected on the heights of Ingouville and Sainte-Adresse. The principal street is the Rue de Paris, running from north to south in the centre of the town, and among the principal promenades may be mentioned the Boulevard de Strasbourg, the Place Louis XVI., and the Jetée du Nord, which terminates in a lighthouse. Havre possesses a tribunal of the first instance, a tribunal of commerce, an exchange and chamber of commerce, a chamber of agriculture, a hydrographic school, and a communal college. The principal buildings are the churches of Notre Dame and St Francis, the new Hôtel de Ville, the Musée, containing apartments for a library, and for art, antiquities, and natural history, and with statues in front of Bernardin de St Pierre and Casimir Delavigne, natives of Havre, by David Angers; the theatre, the clubhouse called the *Cercle du Commerce*, the new palace of justice, the marine arsenal, the town-house, the custom-house, and the Frascati bath-house. The docks are among the finest in the world, and consist of eight separate basins, which, with the late enlargement of the outer harbour, afford 150 acres of accommodation for vessels. The new entrance to the harbour has a width of 100 metres or 328 feet. Lines of rails have lately been laid along the docks. As these have absorbed much of the space on the quays, lading is frequently a slow and tedious process, but the completion of the lately projected harbour will afford all the facilities necessary in this respect. The completion of the proposed canal between Havre and the Seine near Tancarville would be a great commercial benefit to the port whose prosperity has, notwithstanding its advantages as the port of Paris, and its unsurpassed facilities for dock accommodation, been much hampered by the system of centralization, which has both retarded improvements and led to the levying of exorbitant shipping rates. Partly

on this account, not only has France been unable to maintain the transit of goods for Belgium, Switzerland, and Germany, but even much of the traffic of its own northern and eastern provinces has been directed to Antwerp. The latter port is served by an abundant network of railroads and canals, while Havre has only one convenient railroad (that to Paris by Rouen), and the river Seine with its dangers and high tariff. The completion of the scheme for a railway over Montivilliers to Dieppe will afford partial remedy for this state of matters. In the extensive shipbuilding yards of Havre the finest vessels of France are built, and many are also built for other countries. The construction of two new dry-docks has lately been proposed, one of which is to afford accommodation for the largest Atlantic steamers. Havre is now fortified as a fleet station and harbour of war. The port has regular steam communication with London, Liverpool, Southampton, Dublin, Glasgow, Hull, Swansea, Bristol, Dunkirk, Brest, Cherbourg, Rotterdam, Hamburg, Copenhagen, St Petersburg, Constantinople, West Indies, San Francisco, Vancouver Island, and New York. The total number of vessels which entered

the port in 1878 was 6191 with a tonnage of 2,192,778, while 6458 cleared with a tonnage of 2,148,517. For the 5 years ending 1878 the average number of vessels that entered was 6041 with a tonnage of 1,841,265, the number that cleared 6006 with a tonnage of 1,818,189. The average annual value of exports and imports is about 2800 million francs. The trade of Havre with the United States is very large, and it has always retained its superiority in the importation of cotton, one-third of which, however, it imports from other countries than America. It is also the chief port for the exportation of French goods to the United States, and an important point of emigration. Besides cotton its principal imports are petroleum, coals, wheat, woollen, silk, flax, mohair and jute tissues, spices, sugar, coffee, hides, dyewoods, and building timber. The principal exports are various French manufactured cloths, leather, jewellery, agricultural and dairy produce, wine, brandy, and oil. Fishing is extensively prosecuted. Besides the various industries connected with shipbuilding, Havre possesses sugar-refining works, tobacco manufactories, iron foundries, salt works, breweries, vitriol works, and manufactures of *faïence*, lace, silk, and paper. It is also much frequented for sea-bathing. The population in 1872 was 85,538, and in 1876 it was 85,407.

Until 1516 Havre was only a fishing village possessing a chapel dedicated to Notre Dame de Grâce, to which it owes its original name Havre (or harbour) de Grâce. The building of the harbour was begun by Francis I. who gave the town the name of Franciscopolis. At the entrance to the harbour he erected a tower which served as a lighthouse for ships until it was demolished in 1862. The town in 1562 was delivered over to the keeping of Queen Elizabeth by the Prince de Coudé, leader of the Huguenots, and the command of it was entrusted to Ambrose Dudley, earl of Warwick; but the English were expelled within a year, after a most obstinate siege, the progress of which was pressed forward by Charles IX. and his mother, Catherine de' Medici, in person. The defences of the town were greatly strengthened by Henry II. and Louis XIII., and under Louis XIV. it became an important fortress. In the 17th century it was several times vainly besieged by the English, who also bombarded it in 1759, 1794, and 1795. It was a port of considerable importance as early as 1572, and despatched vessels to the whale and cod fishing at Spitzbergen and Newfoundland. In 1672 it became the entrepôt of the French East India Company, and afterwards of the Senegal and Guinea companies. Its development was greatly furthered by Louis XVI., and Napoleon I. raised it to a war harbour of the first rank. Havre is the birthplace of Bernardin de St Pierre, author of *Paul and Virginia*, Casimir Delavigne, Mademoiselle Scudéry, and the naturalists Ancelet and Lesueur.

Morlent, 1847; *Le Havre, son passé, son présent, et son avenir*, by Frederick de Coninck, new edition 1862; Nerval, *Documents relatifs à la fondation de Havre*, 1875.

PLATE
XIII. HAWAIIAN OR SANDWICH ISLANDS, THE, a group of eight inhabited and four uninhabited islands in the North Pacific Ocean, lying between 18° 54' and 22° 2' N. lat. and 155° and 161° W. long. The group has a trend of about N. 64° W., which is nearly the trend of all the Pacific groups. From Honolulu, the capital, on Oahu, the distance to San Francisco is 2100 miles; to Auckland, New Zealand, 3810 miles; to Sydney, New South Wales, 4484 miles; to Yokohama, 3440 miles; to Hongkong, 4893 miles; to Tahiti, 2380 miles. The first of the names by which the group is designated above is taken from that of the largest island Hawaii, and is the name adopted by the inhabitants. The other name was given to it by Captain Cook the discoverer, in honour of the earl of Sandwich, first lord of the Admiralty at the time of the discovery.

History.—These islands, the most important Polynesian group in the North Pacific, were discovered by Captain Cook in 1778.¹ He was received by the natives with many demonstrations of astonishment and delight; and offerings and prayers were presented to him by their priest in one of the temples; and though in the following year he was killed by a native when he landed in Kealakekua bay in Hawaii, his bones were preserved by the priests and continued to receive offerings and homage from the people, until the abolition of idolatry. At the time of Cook's visit each island had its chief. On the death of the chief who ruled Hawaii at that time there succeeded one named Kamehameha, who appears to have been a man of quick perception and great force of character. When Vancouver visited the islands in 1792, this chief being desirous of possessing a vessel on the European model, the keel of one was laid down for him. Ten or twelve years later Mr Turnbull found him with 20 vessels of from 25 to 50 tons which traded amongst the islands, and he afterwards purchased others from foreigners. Having encouraged a warlike spirit in his people and introduced firearms, Kamehameha attacked and overcame the chiefs of the other islands one after another, until he became undisputed master of the whole group. He encouraged trade with foreigners, and derived from its profits a large increase of revenue as well as the means of consolidating his power. He died in 1819, and was succeeded by his son, a mild and well-disposed prince, but destitute of his father's energy. One of the first acts of Kamehameha II. was to abolish *tabu* and idolatry through-

¹ According to the *Boletín de la Soc. Geogr. de Madrid*, 1877, there had been a previous discovery by the Spaniards.

out the islands. Some disturbances were caused thereby, but the insurgents were defeated and the peace of the islands has been scarcely broken since. In 1820 missionaries arrived from America and commenced their labours at Honolulu. A short time afterwards the British Government presented a small schooner to the king, and this afforded an opportunity for the Rev William Ellis, the well-known English missionary, to visit Honolulu, along with a number of Christian natives from the Society Islands. Finding the language of the two groups nearly the same, Mr Ellis, who had spent several years in the southern islands, was able to assist the American missionaries in reducing the Hawaiian language to a written form. In 1824 the king and queen of these islands paid a visit to England, and both died there of measles. For many years the Hawaiians have continued to advance steadily in intelligence, resources, and civilization, but their progress has been at times interrupted by the conduct of the officers of foreign powers. On one occasion a British officer went so far as to take possession of Oahu and establish a commission for its government; and French officers abrogated the laws, dictated treaties, and by force of arms established the Roman Catholic religion in the country. The act of the British officer was disavowed by his superiors as soon as known; and these outrages led to a representation on the part of the native sovereign to the Governments of Great Britain, France, and the United States of America, and the independence of the islands was guaranteed by these powers in 1844. Kalakaua, the reigning monarch (1880), was elected king by ballot on Lunalilo's death without heirs in 1874. The heir to the throne is a sister of the king, Lelia Kamakacha, and is married to an American.

Inhabitants.—By the census taken in December 1878 the population of the whole group amounted to 57,985 persons, instead of 56,897 as in 1873. The number of natives of pure Hawaiian race was 44,088, of half castes 3420, Chinese 5916, Americans (U.S.) 1276, British 883, Portuguese 430, Germans 272, French 81, other foreigners 666, and Hawaiians born of foreign parents 947.

The natives belong to the Malayo-Polynesian race. Their reddish-brown skin has been compared to the hue of tarnished copper. The hair, usually raven black, is straight or at most wavy; the beard is thin, the face broad, the profile not prominent, the nose rather flattened, and the lips thick. The bulk of the population are of moderate stature, but the chiefs and the women of their families are remarkable for height.

"The inhabitants of these islands," says Mr Ellis,² "are, considered physically, amongst the finest races in the Pacific, bearing the strongest resemblance to the New Zealanders in stature, and in their well-developed muscular limbs. The tattooing on their bodies is less artistic than that of the New Zealanders, and much more limited than among some of the other islanders. They are also more hardy and industrious than those living nearer the equator. This in all probability arises from their salubrious climate, and the comparative sterility of their soil, rendering them dependent upon the cultivation of the ground for the yam, the arum, and the sweet potato, their chief articles of food. Though, like all undisciplined races, the Sandwich Islanders have proved deficient in firm and steady perseverance, they manifest considerable intellectual capability. Their moral character, when first visited by Europeans, was not superior to that of other islanders; and, excepting when improved and preserved by the influences of Christianity, it has suffered much from the vices of intemperance and licentiousness introduced by foreigners. Polygamy prevailed among the chiefs and rulers, and women were subject to all the humiliations of the tabu system, which subjected them to many privations, and kept them socially in a condition of inferiority to the other sex. Infanticide was practised to some extent, the children destroyed being chiefly females. Though less superstitious than the Tahitians, the idolatry of the Sandwich Islanders was equally barbarous and sanguinary, as, in addition to the chief objects of worship included in the myth-

² Mr Ellis was the writer of the article POLYNESIA, which included an account of the Hawaiian Islands, in the last edition of this work.

HAYTI (OR SAN DOMINGO)

ology of the other islands, the supernatural beings supposed to reside in the volcanoes and direct the action of subterranean fires rendered the gods objects of peculiar terror. Human sacrifices were slain on several occasions, and vast offerings presented to the spirits supposed to preside over the volcanoes, especially during the periods of actual eruptions. The requisitions of their idolatry were severe, and its rites cruel and bloody. Grotesque and repulsive wooden figures, animals, and the bones of chiefs were the objects of worship. Human sacrifices were offered whenever a temple was to be dedicated, or a chief was sick, or a war was to be undertaken; and these occasions were frequent. The apprehensions of the people with regard to a future state were undefined, but fearful. The lower orders expected to be slowly devoured by evil spirits, or to dwell with the gods in burning mountains. The several trades, such as that of the fisherman, the tiller of the ground, and the builder of canoes and houses, had each their presiding deities. Household gods were also kept, which the natives worshipped in their habitations. One merciful provision, however, had existed from time immemorial, and that was sacred inclosures, places of refuge into which those who fled in time of war, or from any violent pursuer, might enter and be safe. To violate their sanctity was one of the greatest crimes of which a man could be guilty."

In the former state of society the habits of the people were extremely licentious; men were living with several wives, and women with several husbands. Female virtue was an unknown thing, and there is no native word for it. This state of things has, however, been greatly altered by the exertions of the missionaries.

As regards cannibalism, it appears that the heart and liver of the human victims offered in the temples were eaten as a religious rite, and that the same parts of any prominent warrior slain in battle were devoured by the victor chiefs in the belief that they would thereby inherit the valour of the dead man. When, on the death of the great warrior Kamehameha I, the chiefs assembled to deliberate what should be done with his body, one suggested that they should eat it, but this did not find favour with the others.

The Hawaiians are a good-tempered, light-hearted, and pleasure-loving race. They have many games and sports, and the women spend much time in making flower garlands. Both sexes are passionately fond of riding, almost every one being in possession of a horse. They delight to be in the water, and swim with remarkable skill and ease. In the exciting sport of surf swimming, which always astonishes strangers, they balance themselves whilst standing or sitting on a small board which is carried landwards on the curling crest of a great roller.

In spite of moral and material progress—better food, better clothing, improved dwellings, and many other advantages of civilization—the race is dying out, and, indeed, is threatened with extinction in the course of a few years. Captain Cook estimated the number of natives at 400,000; in 1823 the American missionaries calculated them to be only 142,000; the census of 1832 showed the population to be 130,313; and the census of 1878 proved that the number of natives was no more than 44,088. To account for this it is said that the blood of the race has become poisoned by the introduction of foreign diseases. The women are much less numerous than the men; and the married ones have few children at the most; two out of three have none. Moreover the mothers appear to have little maternal instinct, and there is consequently a neglect of the offspring. Whilst the Hawaiians are decreasing, the Chinese are coming in large numbers, and threaten in time to take their place. To counteract this, as well as to supply the pressing need for labourers, the Government has considered many schemes for introducing other immigrants. Polynesians from other islands have been brought over, and a considerable number of Portuguese have come from Madeira.

The language is a branch of the widely-diffused Malayo-Polynesian tongue; and Hawaiians and New-Zealanders, although occupying the most remote regions north and south at which any of their race have been found, can understand each other without much difficulty. This language

is soft and harmonious, being highly vocalic in structure. The only consonants are *k*, *l*, *m*, *n*, and *p*, which with the gently aspirated *h*, the five vowels, and the vocalic *w*, make up all the letters in use. The letters *r* and *t* have been suppressed of late years in favour of *l* and *k*, so that, for example, *taro*, the former name of the *Colocasia* plant, is now *kalo*. The language was not reduced to a written form until after the arrival of the missionaries.¹

In the days of idolatry the only dress worn by the men was a narrow strip of cloth wound round the loins and passed between the legs. Women wore a short petticoat made of *tapa* (cloth prepared from the inner bark of the paper mulberry), which reached from the waist to the knee. But now the common class of men wear a shirt and trousers, whilst the better class are attired in the European fashion. The women are clad universally in the *holoka*, a loose white or coloured garment with sleeves reaching from the neck to the feet. A coloured handkerchief is twisted round the head or a straw hat is worn. Both sexes delight in adorning themselves with garlands (*leis*) of flowers and necklaces of coloured seeds.

The natives derive their sustenance chiefly from pork and fish both fresh and dried, and from the *kalo* (*Colocasia esculenta*), the banana, sweet potato, yam, bread-fruit, and cocoa-nut. The root of the *kalo* affords the national dish called *poi*; after having been baked and well beaten on a board with a stone pestle it is made into a paste with water and then allowed to ferment for a few days, when it is fit to eat. There was formerly a particular breed of dog which, after being fed exclusively on *poi*, was considered a great delicacy. The filthy liquor called *awa* or *kawa* is still relished by the natives, and though it is only allowed to be made under licence, it is often prepared clandestinely.

The native dwellings are constructed of wood, or more frequently are huts thatched with grass at the sides and top. What little cooking is undertaken is done outside. The oven consists of a hole in the ground in which a fire is lighted and stones made hot; and the fire having been removed, the food is wrapped up in leaves and placed in the hole beside the hot stones and covered up until ready.

Leprosy is prevalent amongst the natives, and the Government has established a settlement on the island of Molokai where all persons found to be affected with the disease are kept entirely isolated from the healthy part of the community. The lepera number about 800.

Agriculture and Commerce.—Large capital has been embarked, chiefly by Americans, in the production of sugar, the soil and climate being well suited to the cane in those localities where the water supply is ample. There are between 60 and 70 sugar estates, and more are being planted. The principal difficulty is the want of labour. The average yield of sugar per acre is 2½ tons, whilst in some favoured spots as much as 7 tons has been obtained. In 1878 the exports of sugar amounted to 17,187 tons. Rice is also largely cultivated, 2455 tons having been exported in the same year. Coffee is produced only to a small extent. Arrow-root is prepared from the root of the *Tacca pinnatifida*. The *kalo* plant (*Colocasia esculenta*) is extensively grown in wet places. It is said that a patch of *kalo* measuring 40 feet square yields sufficient food for a native for a whole year; a square mile of it would therefore support 17,000 persons. Maize and wheat are raised, and flour is manufactured. Pine apples, oranges, mangoes, custard apples, guavas, and many other fruits have been introduced, and flourish in gardens. A silky fibre called *pulu*, growing on the crown of tree-fern stems belonging to the genus *Cibotium*, is exported in large quantities to America, where it is used for stuffing cushions.

The owners of sheep are few, but they have large flocks, and the wool exported in 1878 amounted to 523,000 lb. Some districts are well suited for cattle raising. The wild cattle on the mountains—a very inferior breed, descended from some left by Captain Vancouver—are shot or taken with the lasso for the sake of their hides, which are exported in large quantities. In one island 11,000 were killed in a single year. The natives used to entrap them by digging pits

¹ See Chamisso, *Ueber die Hawaiische Sprache* (Leipsic, 1837); and Andrews, *Grammar of the Hawaiian Language* (Honolulu, 1854), and *Dictionary* (Honolulu, 1865).

near pools of water, and it was through falling into one of these pits that Douglas, the botanical collector, met his death by being gored by a bull.

Owing to their geographical position the commercial development of the islands has advanced even more rapidly than the material improvement in the circumstances of the people. A treaty of commerce was concluded in 1876 between the United States and the Hawaiian Islands, under which the manufactures of the former and the chief productions of the latter are reciprocally allowed to enter duty free. This treaty has been of great benefit to the islands, more especially by stimulating the cultivation of the sugar cane. The principal exports are sugar, rice, coffee, hides, skins, tallow, and wool. In 1873 the total amount of exports reached the value of about 3,500,000 dollars, whilst the value of imports amounted to about 3,000,000 dollars. The United States are by far the largest customers for the articles exported, and supply the great bulk of the imported goods. In 1878 there were 54 vessels registered under the Hawaiian flag, of which 11 were engaged in whaling and foreign trades, whilst 43 were coasters, making a total of 8000 tons. In 1878, besides the mail steamers, 216 merchant vessels of various foreign nations entered the Hawaiian ports.

Many good roads have been made, and railways have been projected; a telegraph line was opened in 1878 between Wailuku and Lahaina in Maui (40 miles), and has since been extended; considerable capital has been brought in by foreigners; and the price of land is rising. A Government survey of the islands is in progress.

Climate and Meteorology.—The climate in general is warm but very salubrious. The temperature is equable and the sky usually cloudless. The N.E. trades blow for nine months; and the leeward coast, being protected by high mountains, is refreshed by regular land and sea breezes. During January, February, and March the wind blows strongly from the S.W.; and at this season an unpleasant hot damp wind from the equatorial region occasionally makes itself felt. Very much more rain falls on the windward side of the principal islands than on the leeward. Thus at Hilo, on the east coast of Hawaii, the usual rainfall is said to amount to 80 inches, and in some years to more than twice that quantity, whilst at Honolulu on the south coast of Oahu, out of the reach of the windward rains, the mean annual rainfall for the five years ending 1877 varied from 32.30 to 46.40 inches, the average being about 38. The mean annual temperature at the same place for the same period was 75° Fahr. The mean temperature of the coldest month during the five years was 62° Fahr., and that of the hottest month 81° Fahr. Strong gales blow once or twice during the winter, but destructive hurricanes are entirely unknown.

Zoology.—When Cook arrived at the islands he found only hogs, dogs, and rats. There is a day-flying bat; a small lizard is found, but no other reptiles. Cattle, goats, and hogs at the present day run wild upon the mountains in the larger islands, and do much damage to the woods. As to the birds, fifty-three species have been enumerated by Mr Sanford Dole in *Proceedings of Boston Soc. of Natural History* (cf. Selater's paper in *Ibis*, 1871), but it is thought that many more species remain to be discovered in the mountain districts. In former times the chiefs exacted as a tax from the people the gay feathers of certain species (*Drepanus* and *Moho*), and employed them to ornament their state robes, only one of which is now in existence, and that is kept with the greatest care for the king's use on state occasions. Mr Dole's list includes of *Falconidae* 2 species, *Strigidae* 1, *Promeropidae* 10, *Meliphagidae* 4, *Turdidae* 2, *Ampelezidae* 1, *Corvidae* 1, *Fringillidae* 5, *Charadriidae* 2, *Scelopacidae* 3, *Ardeidae* 2, *Rallidae* 5, *Anatidae* 3, *Procellariidae* 2, *Laridae* 5, and *Pelicanidae* 3. One of the *Rallidae*, now nearly extinct, is remarkable for having rudimentary wings, like the moa of New Zealand, hidden in long, loose, hairy feathers. Dr Otto Finsch, who visited Honolulu in 1879, says that the native birds, as well as the native plants, are being ousted by introduced species. The house sparrow from Europe and the maina (*Aerodoleres tristis*?) and the turtle-dove (*Turtur chinensis*) from China are almost the only birds to be seen in and about the town; and in order to obtain specimens of indigenous species he had to go far inland. (See *Proceed. Roy. Geog. Soc.*, Jan. 1880.)

Botany.—The ravines and mountain slopes on the windward side of the larger islands contain much forest growth, whilst the leeward uplands and plains are comparatively bare. Amongst the more remarkable forms are a *Pandanus*, or screw pine, and the *Aleurites*, or candle-nut tree, so named from the natives stringing together the kernels, which are very oily, and so making a candle. Sandalwood, formerly plentiful, has been exhausted. The cocoa-nut palm grows in abundance on the coast. For the following valuable notes on the flora, we are indebted to Dr William Hillebrand, who for many years studied the subject on the spot with the view of publishing a complete work upon it:—

"The flora of these islands, according to my researches, comprises 829 species of phanerogams and 147 species of vascular cryptogams. These 976 species are distributed amongst 353 genera. There are 144 species of monocotyledons, of which 45 belong to the *Cyperaceae* and 63 to the *Gramineae*. Only 3 species of orchids have been

round. Of the 829 species of phanerogamous plants 94 are known to have been introduced since the advent of the white man, whilst 597 species are peculiar to the islands, leaving only 133 species which are found elsewhere. With few exceptions the peculiar genera are the richest in species, but some of the genera not entirely Hawaiian are also remarkable for the number of their species; for example, *Cyrtandra* has 29 species, *Piperonia* 21, *Pitiosporum* 12, and *Euphorbia* 10. Amongst the peculiar dicotyledonous plants there is not a single annual; and by far the greater number are arborescent or frutescent. There are only two native species of palm, both belonging to the genus *Prilchardia*. Of ferns there are 130 species, including 35 of *Asplenium*, 16 of *Aspidium*, 16 of *Polypodium*, and 8 of *Phegopteris*. The tree ferns number 5 species, 3 belonging to the genus *Cibotium*, and 2 to *Sadleria*. As to the derivation of the flora a distinction must be made between the lower and middle regions and the upper mountainous region. The two former are manifestly connected with the south-western Polynesian and Malaysian flora, so far as the latter is represented by the Moluccas and New Guinea, and connected by Wallace with the Australian continent. Some of the prevailing forest trees of the lower region are identical with the species found in the localities just mentioned, e.g., *Aleurites moluccana*, *Jambosa malaccensis*, *Alphidoxia excelsa*, *Dodonaea viscosa*, *Thespesia populnea*, *Cordia subcordata*, *Artocarpus incisa*, *Paritium tiliaceum*, *Broussonetia papyrifera*, and *Cordyline terminalis*. Most of the forest trees of the middle belt, although peculiar as species, have very near congeners in the same direction, as *Metrosideros polymorpha*, *Acacia Koa* (with *phylloidia*), the *Pelcas*, *Pseudopanax*, *Gouldia*, *Sophora*, *Elacarpus*, *Pitiosporum*, *Boea*, *Straussia*, *Cyprosma*, *Maba*, *Sapota*, *Myrsine*, *Olea*, *Pisonia*, *Santalum*, *Charpentiera*, &c. But with regard to the flora of the highest region in the Hawaiian Islands, there are many plants and some entire orders which point to the American continent as the land of their nearest allies,—for instance, the *Compositae* with few exceptions, the *Rosaceae*, *Geraniaceae*, and most of the *Labiatae*."

Geology and Mineralogy.—Though the islands are mountainous, none of the eminences reach the limit of perpetual snow. All the islands are of volcanic origin and are entirely composed of the products of eruption. On one of them (Hawaii) the volcanic forces are still in operation; on all the others they have been quiescent for an indefinite period, and the superficial rocks are in a more or less advanced state of decay. Where volcanic action has long ceased deep ravines have been excavated on the sides of the mountains, and this is especially the case on the windward side of Hawaii, where the rainfall is very large. The headlands frequently terminate in lofty cliffs, sometimes overhanging the sea to a height of 2000 feet; and these afford additional evidence of a prolonged period of repose. The products of the Hawaiian volcanoes are rather scanty. According to Mr Brigham they consist of hydrochloric, sulphuric, and sulphurous acids, native sulphur, pyrites, common salt, sal ammoniac, hæmatite, quartz, palagonite, felspar, chrysolite, thomsonite, gypsum, solfatarite, copperas, nitre, arragonite, labradorite, and limonite. Evidence of slight upheaval is furnished by those parts of the shore where old coral reefs are found, sometimes as high as 100 feet above the sea.

Government and Laws.—The form of government is a constitutional monarchy, with a legislature composed of 20 nobles appointed by the king for life, and 28 representatives elected every two years by the people—the two classes sitting together. An annual income of 75 dollars is the qualification of an elector. The king has a cabinet of ministers and a privy council. The Government is regularly organized, its departments are efficiently managed, and the laws are justly administered. Many of the principal offices are filled by foreigners, chiefly Americans, who have become Hawaiian subjects. It is somewhat of a burlesque of the proceedings of royalty in Europe that here, where the whole body of subjects is less than the population of a small English county, we find in full display the titles of majesty, royal highness, prince, excellency, &c., as well as knights grand cross and other grades of two royal orders! A governor is appointed by the king for each of the larger islands. Diplomatic representatives of Great Britain, France, and the United States of America are resident at Honolulu, and also consuls of these and other foreign powers. At London, Paris, New York, and several other foreign cities there are Hawaiian diplomatic and consular agents. An efficient postal system has been established, and there is a standing army of about 70 men. The laws are modelled on those of the United States. There is a supreme court of justice, as well as circuit judges and district justices, assisted by a police force.

Religion and Education.—The ancient idolatrous religion has been abandoned since 1819, and the whole population has embraced Christianity. All forms are tolerated, and at Honolulu there are six churches belonging to the Roman Catholic, Protestant Episcopal, and Congregational communions. The bishop of the Church of England is styled the bishop of Honolulu, and the Roman Catholics have also a bishop. The Congregationalists are most numerous. Originally started by the foreign missionaries, the question of education has been taken up by the Government,

who have established a board to superintend the affairs connected with this subject. Nearly every native can read and write. In 1878 there were 222 schools, attended by 3991 boys and 3000 girls. In the majority of these schools the instruction is communicated in Hawaiian; but in some of a higher grade English is employed, and, as the people themselves desire it, that language is more and more introduced.

Revenue and Currency.—The annual revenue of the Government amounts to about 600,000 dollars derived chiefly from custom duties (284,000 dollars in 1878), taxes on real and personal property, and a poll tax. It does not equal the expenditure, and there is a funded debt of from 400,000 to 500,000 dollars. Accounts are kept in dollars, and the coins in circulation are those of American States.

The Capital.—Honolulu (population 14,114), the capital of the island group, stands on the S.W. coast of Oahu, in 157° 51' 48" W. long. and 21° 17' 56" N. lat., at the mouth of the valley of Nuanu, which runs back between tall cliffs to two peaks about 3000 feet high in the great eastern range of mountains. It is the seat of the central government and the residence of the king. Although consisting largely of one-story wooden houses, mingled with grass huts half smothered by foliage, Honolulu is said to present to approaching vessels more of the appearance of a civilized place with its churches and public buildings than any other town in Polynesia. The streets, laid out in the American style, are straight, neat, and tidy. Water-works supply the town from a neighbouring valley. Among the stone erections are the king's house, a hospital, a large hotel built by the Government, and the Government buildings, in which are a fair library of English books and a museum containing corals, shells, and other natural curiosities, as well as specimens of ancient weapons and other native articles. Amongst the brick buildings are large iron works, a brass foundry, an establishment for working up wood, and rice mills. All the necessaries and most of the luxuries of civilized life can be obtained in Honolulu. There are several hotels for the accommodation of strangers, and numerous agencies of both British and American insurance offices; American and English medical men and lawyers have settled in the town; two weekly newspapers in English and two in the Hawaiian language are published. Honolulu has a good natural harbour, with wharves, a custom house, and warehouses. It is connected by regular lines of mail steamers with San Francisco, Sydney, and New Zealand. There are also lines of steamers to Liverpool and Glasgow, New York and Boston, Bremen, China, and Peru. Small steamers ply between the islands. Business is almost entirely carried on by foreigners, and chiefly by Americans, British, Germans, and Chinese. The last are the most numerous; they are acquiring property rapidly, and some of them are wealthy. The foreigners are very sociable, and have established numerous clubs, benevolent societies, &c. American influence and customs are said to be dominant. In the neighbourhood of the town is a college, where for a small sum boys and girls receive a good English education.

The Separate Islands.—The following description of the separate islands begins with the largest and most easterly, giving the others in the order of their position.

Islands.	Length in Miles.	Width in Miles.	Estimated Area in Acres.	Population. Census 1878.
Hawaii	100	90	2,500,000	17,034
Mauī	54	25	400,000	12,109
Kahulawī	12	5	30,000	60
Lanai	20	9	100,000	214
Molokai	35	7	200,000	2,581
Oahu	35	21	350,000	20,236
Kauai	30	28	350,000	5,634
Niihau	20	5	70,000	117
			4,000,000	57,985

In older English works Hawaii is called Owhyhee and Maui Mowee. The four uninhabited islets are named Nihoa, Kaula, Lohua, and Molokini.

HAWAII has an area nearly double that of all the other islands put together. In shape it is a rude triangle, with sides of 85, 75, and 65 geographical miles in length. Almost the whole of its surface is occupied by the gentle slopes of four volcanic mountains, Mauna Kea on the N., 13,805 feet in height (the highest peak in the Pacific Ocean); Mauna Loa on the S., 13,600 feet; Mauna Hualalai on the W., 8275 feet; and Mauna Kohala on the N.W., 5505 feet.

The highest points of Mauna Kea are truncated cones with craters rising from plains of clinkers and gravel, ashes and sand; but no modern streams of lava are visible, nor is there record of any eruption of this mountain. The slopes on the west side are so gentle that the base of the terminal cones may be reached on horseback. On the windward side cryptogamic vegetation reaches as high as 12,000 feet, but the forest ceases at 6000 feet.

Mauna Loa is the most interesting mountain of the whole group from its being still an active volcano. The circular terminal crater,

8000 feet in diameter, is quite perfect, with nearly vertical walls from 500 to 600 feet high on the inner side; and the bottom between the numerous cones is usually covered with solid lava, from the fissures of which issue steam and sulphurous vapours; but its features change with every eruption. There is no record of any eruption from Mauna Loa before 1832, when lava flowed from the summit crater on several sides. In 1843 a vast flood of lava was discharged, which formed three streams 5 or 6 miles wide and between 20 and 30 miles long. There were eruptions in 1851, 1852, 1855, and 1859, but in none of these did the lava reach the sea except on the last occasion, when the eruption continued for two months, and a winding current 50 miles long, from 1 to 5 miles wide, and from 10 to some hundreds of feet thick, arrived at the west coast in eight days. Its surface is now black, shining, brittle, and very porous. In 1868 occurred another eruption attended by many earthquakes. One of these caused a huge sea wave 40 feet high to break on the shore, occasioning the loss of many lives and the destruction of much property. The wave crossed the Pacific to the Californian coast. Later in the same year, at a time when earthquakes were taking place on the coast of South America and the town of Iquique in Peru was destroyed, a great wave came across the Pacific, struck the Hawaiian Islands, and made itself felt in New Zealand. The last eruption took place in February 1877, when a stream of lava flowed for six hours.

Sixteen miles to the S.E. of Mauna Loa is a hill called Kilauea, with a crater which is the largest active one in the world. The earliest recorded eruption was in 1789, and there was another in 1832. This volcano was first made known to the civilized world in 1823, when Mr Ellis and a party of American missionaries visited it. At an elevation of 4400 feet above the sea they found in the midst of a plain an oval crater 9 miles in circumference with vertical sides 1000 feet deep, covered at the bottom with a lake of liquid lava at one end red and boiling. Around the edge or from the midst of this fiery lake, 51 conical craters sent forth jets of lava or smoke and flame. A stony ledge round the inside of the crater, and 300 or 400 feet above the lake, indicated that the lava had risen to that height and had then run off by a subterranean channel to the sea, where some miles of coast had been filled up with liquid lava a few weeks previously. Since that time many travellers have ascended to the craters of both Mauna Loa and Kilauea, and have given vivid descriptions of the very grand and wonderful phenomena they witnessed. In 1840 the commander and officers of the United States Exploring Expedition spent three weeks on the summit of Mauna Loa and made an accurate survey of the crater. In that year there was a great outburst from a crater 8 miles from the summit of Kilauea, when a stream of lava half a mile broad and 40 miles long reached the sea.

Over the whole summit of Hualalai, another of the four mountains of Hawaii, are scattered many pit craters from 300 to 500 feet deep and from 700 to 1000 feet in diameter, their solid walls being nearly vertical. On the edge of one of the deepest craters there is a mound about 50 feet high, composed of drops of lava and fragments of all sizes, coloured yellow, orange, red, blue, and black. They seem to have been ejected in a viscid state, for they are slightly agglutinated together. In the centre of the mound is a blow-hole 25 feet in diameter and about 1800 feet deep. The inside of this hole is grooved horizontally, but otherwise smooth as if turned. More than 150 cones have been counted on the sides of Hualai. The last eruption took place in 1801, when a copious flow of lava reached the coast, where it filled up a deep bay.

The lavas of Hawaii are distinguishable according to the aspect of their surface into three classes. 1. The *pahoehoe* of the natives, or velvety lava, is folded and twisted in a manner that shows it was once a viscid fluid. This is the common form when the flow has passed over rocks or dry ground on a gentle slope. 2. The clinkers or scoriaceous lava is rough and covered with fragments. This is found wherever the stream has passed through woods or has been impeded by inequalities of the ground, or where its heat has caused the explosion of caverns beneath the floor of older beds. 3. The *a-a* or spongy lava, which, on account of its extreme roughness and hardness, is carefully avoided by all travellers. This form is thought to owe its origin to the fact that, just as the lava was granulating, impediments that stood in its course gave way, when the spongy mass rolled over and built up piles from which the liquid portion drained off. The natives are in the habit of making holes in the *a-a*, and planting in them banana shoots or sweet-potato cuttings, and though the holes are simply filled with stones or fern leaves the plants grow and in due time are productive.

The plain lying between the mountains of Hawaii is many square

Amongst the minor phenomena they speak of the delicate glassy fibres called Pele's hair by the Hawaiians, which are spun by the wind from the rising and falling drops of liquid lava, and blown over the edge or into the crevices of the crater. Pele is idolatrously times was the dreaded goddess of the volcano. It is noteworthy that a substance resembling Pele's hair is made from the slag of iron furnaces, by driving steam or air against a thin current of the melted slag. The fibrous material thus made has been termed mineral or slag wool: it can be woven into sheets which are useful for coating steam boilers, &c., as the substance is a very bad conductor of heat.

miles in extent, and is intersected by lava streams which have issued from the three nearest volcanoes. The rocks forming the north point of Kealakenkua bay, where Captain Cook was killed, are part of a flow which may be traced up the steep ascent and over a precipice where it must have fallen like a cascade, the surface being curiously marked with waves and curves as if the molten stone had been solidified instantaneously. A sheet of copper with an inscription, attached to the stump of a cocoa-nut palm, for many years served as the only memorial of Captain Cook's death; but in 1874 a monument was erected at the spot by the residents of Honolulu. The east coast of Hawaii from Hilo to Laupahoehoe, a distance of 30 miles, is very remarkable for the streams, 85 in number, running at the bottom of ravines 1800 or 2000 feet in depth which are cut into the side of Mauna Kea, and render travelling along this coast a work of extreme labour. The ridges between the ravines terminate at the sea in precipices from 100 to 500 feet high, so that the road is obliged to run inland into and across the ravines.

At a point midway between the three southern mountains, and at a height of 5000 feet, are the ruins of the ancient temple of Kaili, 92 feet long, which formerly contained many idols.

Hilo (population 4290), the residence of the governor, is a straggling village half hidden in sugar-cane and other vegetation on the east coast. It lies in a bay that is little more than an open roadstead, but is partly protected from heavy seas by a sunken coral reef.

MAUI, lying 25 miles N.W. of Hawaii, is composed of two mountains connected by a sandy isthmus 7 or 8 miles long by 6 miles across, and so low that the depression of a few feet would convert Maui into two islands. Haleakala, the mountain to the N.W., has a height of 10,032 feet, and forms a great dome-like mass with a circumference at the base of 90 miles, and with regular slopes of only 8° or 9°, so that travellers may ride to the top on horseback. The extinct crater on its summit, the largest in the world, has a length from E. to W. of 7½ miles, and a width of 2½ miles, with an area of about 16 square miles. The circuit of the walls, which are composed of a hard grey clinkstone much fissured, is from 18 to 20 miles. The depth, measured from the highest point of the rim, is 2720 feet. At the bottom are 16 cones 500 or 600 feet high, formed long after the top of the great crater had been destroyed, perhaps by explosions. On the east and north are two great gaps in the walls from 1 to 3 miles wide, through each of which has poured a copious flood of lava which nearly reached the sea. These streams, though of unknown date are comparatively modern, for they have blocked up several ravines in their progress. A little impure sulphur is found in the crater, but there is not the least sign of igneous activity at present on the island. Eeeka, the mountain at the south-east of Maui, is 5820 feet high. Volcanic action appears to have ceased here at a much earlier period than on Haleakala, there being no craters on the summit or sides, whilst the slopes have been denuded into deep valleys separated by narrow sharp ridges.

Lahaina (population 3000), on the north-west shore, is the residence of the governor. It is a decaying place situated in a grove of coconut and other tropical trees. The roadstead is roomy and sheltered, and there is regular steam communication with Honolulu, about 72 miles distant. A native Hawaiian college in the neighbourhood is supported by Government. Foreigners reside at Lahaina, as well as at **Wailuku** (population 4000), a town on the east shore of the island. They are principally employed in the cultivation of sugar.

KAHULAWI is a small island 6 miles west of Maui. Though the vegetation is scanty and there are no streams, it has been leased by the Government for sheep pasture. The highest point is only about 1130 feet above the sea, and there are no ravines.

LANAI is another small island on the west of Maui, from which it is 9 miles distant. At the south-east end there is a mountain 3000 feet high without a crater. Vegetation is stunted on the exposed slopes, but the ravines contain a rich growth of trees and shrubs. Sheep in large numbers are pastured here. Lanai and Kahulawi are remarkable for presenting high cliffs to the leeward and gentle slopes to the windward, the reverse being the case in all the other islands.

MOLOKAI is a long narrow island 9 miles distant from the north-west end of Maui. A ridge of hill forms its backbone and throws off lateral spurs enclosing ravines. At the west end are some lofty broken peaks, the highest of which is about 3500 feet above the sea. Deer are wild on the hills, the descendants of tame animals that belonged to a former king. The leper settlement of Molokai has been already mentioned.

OAHU, 23 miles N.W. of Molokai and 67 miles S.E. of Kauai, has an irregular quadrangular form. It is traversed from S.E. to N.W. by two parallel ranges of hills separated by a low plain. The highest point in the island is Kaula, 4060 feet, in the western range; but the eastern range is much longer than the other, and its ridge is very broken: on the land side there are many ravines formed by lateral spurs, but for 30 miles on the other side it presents to the sea a nearly vertical wall without a break. The valleys are remarkable for beautiful scenery,—peaks, cliffs, lateral ravines, cascades, and tropical vegetation combining

to charm the eye. There are few craters on the loftier heights, volcanic activity appearing to have long ceased, but on the coast there are several groups of small cones with craters, some of lava, others of tuff. The greater part of the coast is surrounded by a coral reef, often half a mile wide. In several localities an old reef has been upheaved, sometimes to the height of 100 feet, and now forms part of the land. By such an upheaval a bay of the sea a mile wide and two miles long has been converted into a plain some 25 feet above the level of the ocean, and upon this plain stands Honolulu, the capital of the kingdom, noticed above.

KAUAI, 67 miles N.W. of Maui and 23 miles from Molokai, has an irregularly circular form; and at the centre is the basaltic mountain Waialeale, 5000 feet high, which has a swampy top and sides deeply furrowed by ravines, showing that volcanic action has been long extinct. To the west of the mountain is a tableland with an elevation of 4000 feet and an area of 40 square miles, terminating at the sea in a precipice of 2000 feet. The valleys are numerous, deep, and very picturesque with wood and waterfalls. The soil is fertile, the lavas of nearly the whole island being much decomposed. In some places, however, are cones which have preserved their craters. Numerous dykes are exposed in the valleys, and there are large caverns in several localities which are thought to have been great bubbles in the lava. In one place near the shore is a bank of calcareous sand which on being set in motion gives out a curious noise. When the grains were examined with the microscope they were found to contain cavities, and it is supposed that these minute hollows are the cause of the resonance, for when the sand is wet the noise is not heard. A district on the north side of the island is considered to be the best watered and most fertile in the entire group; it contains several sugar plantations. In this part the rainy season extends over nine months. The chief town is **Waimoa** (population 1200), which affords the best anchorage in Kauai; it is situated at the mouth of a stream navigable by boats for three quarters of a mile.

NIHAU, the most westerly island of the group, is 15 miles west of Kauai. Two-thirds of it consist of a low plain composed of an uplifted coral reef and matter washed down from the mountains. The hilly portion is destitute of cones, craters, peaks, and ridges. The coast on the side towards Kauai is formed of high cliffs, and from the similarity of the structure of the rocks on the two sides of the strait it is thought that the islands were once united. The soil of Nihaui is dry, yet fertile. The island is the property of a foreigner who pastures about 75,000 sheep upon it. The uninhabited islets of Kaula and Lehua, close to Nihaui, have each of them a tufa cone.

A map of Hawaii is given in Petermann's *Mithteil.*, 1876, and one of the other islands, *ibid.*, 1878. (J. Y. J.)

HAWARDEN, a market-town of Flintshire, North Wales, 8 miles S.W. of Chester, is a clean and tolerably well-built place, situated on an eminence commanding an extensive prospect. It lies in the midst of a coal district, and near it are valuable clay-beds. Coarse earthenware, draining-tiles, and fire-clay bricks form the chief manufactures of the district. The family of Maude derive the title of viscount from the town. Population (1871) of the township, 6782; of the parish (including Saltney), 8683. In the neighbourhood is Hawarden Castle, built in 1752, and added to and altered in the Gothic style in 1814; it stands near the ruins of the old castle of that name which was granted by the Conqueror to his nephew Hugh Lupus, and which after many vicissitudes came into the possession of Serjeant Glynne, lord chief-justice of England under Cromwell. On the death in 1874 of Sir Stephen R. Glynne, the last of a line of baronets, the castle passed to his brother-in-law the eminent statesman Mr W. E. Gladstone.

HAWES, STEPHEN, a minor English poet of the 16th century. Neither the date of his birth nor that of his death has been ascertained, and all the known facts of his life may be stated in a few lines. He was probably a member of a Suffolkshire family, studied at Oxford, with what success we can only conjecture, travelled in England, Scotland, and France, and having acquired the reputation of a man of culture was appointed groom of the chamber to King Henry VII. He was still alive in January 1520–21, as appears by an entry, *Item to Mr Hauwe for his play vj li. xiii s. iij d.* Of the play thus mentioned nothing further is known. The writer's chief work was *The Historie of Graunde Amour and la Bell Pucell, called the Pastime of Pleasure, conteyning the Knowledge of the Seven Sciences and the Course of Man's Life*, a long allegorical poem in the style of Lydgate. Its general method may be guessed from such a heading as *How Science first sent him to Gramer where he was receyved by Dame Congruitie*; and, though it must be confessed that portions of the poem are better both in matter and in workmanship than might be expected, it is now of interest almost exclusively because, in Warton's words, it is "almost the only effort of imagination and invention which had appeared in our poetry since Chaucer." Probably written about 1506, and first printed, it is said, by Wynkyn de Worde, it afterwards went through several editions (J. Wayland, 1554; Richard Tottel, 1555; J. Waley, 1559); a reprint of Tottel's was made for the Percy Society in 1842. Among the minor poems attributed to Hawes it is sufficient to mention his *Conversyon of Suerers* and his *Joyful Medytacyon to all Englonde of Kyng Henry the Eight*. The former, a dry didactic production, was printed by Wynkyn de Worde (1509?) and William Copland (1551). Of the latter the only copy preserved is among Bishop More's books in the public library of the university of Cambridge. Both were edited for the Abbotsford Club by David Laing (1854). For further details see Hazlitt's edition of Warton's *History of English Poetry* (1874), and the Percy and Abbotsford reprints.

HAWES, WILLIAM (1785–1846), an English musician of some merit, is remembered chiefly by the fact that through his instrumentality Weber's *Der Freischütz* was for the first time performed in England. This event took place July 24, 1824, and led eventually to Weber's removal to London. Hawes was born in London in 1785, and was for eight years (1793–1801) a chorister of the Chapel Royal, where he studied music chiefly under Dr. Ayrton. He subsequently held various musical posts, being in 1817 appointed master of the children of the Chapel Royal. He also, in conjunction with Welsh, carried on the business of a music publisher, and was for many years musical director of the Lyceum Theatre, then devoted to English opera. It was in the last-named capacity that he introduced Weber's masterpiece, at first slightly curtailed, but soon afterwards in its entirety. Winter's *Interrupted Sacrifice*, Mozart's *Così fan Tutte*, Marschner's *Vampyre*, and other important works were also brought out under his auspices. Hawes also wrote or compiled the music for numerous pieces, none of which however has survived or deserves mention. Better were his glee and madrigals, of which he published several collections. He also superintended a new edition of the celebrated *Triumph of Oriana*. Hawes died February 18, 1846.

HAWFINCH, a bird so called from the belief that the fruit of the hawthorn (*Crataegus Oxyacantha*) forms its chief food, the *Loxia coccothraustes* of Linnæus, and the *Coccothraustes vulgaris* of modern ornithologists, one of the largest of the Finch family (*Fringillidae*), and found over nearly the whole of Europe, in Africa north of the Atlas, and in Asia from Palestine to Japan. It was formerly

thought to be only an autumnal or winter-visitor to Britain, but later experience has proved that, though there may very likely be an immigration in the fall of the year, it breeds in nearly all the English counties to Yorkshire, and abundantly in those nearest to London. There seems also to be good reason for supposing that it is yearly extending its range in the British Islands. In coloration it bears some resemblance to a Chaffinch, but its much larger size and enormous beak make it easily recognizable, while on closer inspection the singular bill-hook form of some of its wing-feathers will be found to be very remarkable. Though not uncommonly frequenting gardens and orchards, in which as well as in woods it builds its nest, it is exceedingly shy in its habits, so as seldom to afford opportunities for observation. As the genus *Coccothraustes* is now commonly restricted, it includes but this single species,—the Japanese form, at one time regarded as distinct, being considered by the latest authorities to be inseparable. (A. N.)

HAWICK, a municipal and parliamentary borough of Roxburghshire in Scotland, 10 miles S.W. of Jedburgh, and 53 miles S.S.E. of Edinburgh by rail, is situated on the south bank of the Teviot at its junction with the Slitrig, a wild and irregular stream that flows through the town. A handsome bridge, spanning the Teviot, connects Hawick with the manufacturing village of Wilton, which is practically a suburb. The town is fairly well built, the main street being broad and well paved. The ancient tower of the barons of Drumlanrig is now occupied as an inn; and many of the older houses testify by their massive proportions to the former dangers of Hawick's position as a border town. The tower was the only building not burned down in 1570 by the earl of Sussex. The parish church of St Mary has succeeded one mentioned in the *Chronicle of Melrose* as having been consecrated in 1214,—a fact which speaks for the antiquity of the town. Additional testimony is afforded by the Moathill at one end of the town, an earthen mound of great antiquity, about 30 feet high. The present town-charter, granted in 1537 by a baron of Drumlanrig, was confirmed in 1545 by Queen Mary during a residence in the town. Hawick, with Wilton, was in 1868 erected into a parliamentary burgh, uniting with Galashiels and Selkirk in sending a member to parliament. The municipal government is vested in a town council, consisting of a provost, four magistrates, and ten councillors. The exchange, built in 1865, contains a free public library. Hawick possesses a very complete system of underground drainage, in connexion with purification works,—this being the first experiment of the kind on a large scale in Scotland.

The manufactures of Hawick are mentioned in the burgh records so far back as 1640, but they must have been flourishing for some time before that, as the weavers already formed an important part of the population. The weavers then worked each for himself, executing his private orders; and it is not till the middle of the following century that a number of looms under one employer are heard of. Linen was at first the chief article of manufacture, but woollen plaidings were also made. Wool was also spun and sold to be manufactured elsewhere. A carpet factory was begun in 1752, and the manufacture of linen tapes or inkle started a few years afterwards, but both industries became extinct towards the beginning of the present century. The manufacture of tweeds is the most important industry of Hawick. In this branch the annual turn-over is about £800,000; while in the whole woollen trade it is about £2,000,000. The manufacture of hosiery, to which the town owes so much of its prosperity, was introduced in 1771, when four looms, employing six men and five women, produced annually about 2400 pairs of coarse stockings. Hawick has gradually become the chief seat of this trade in Scotland. Some of the yarn spun at Hawick is sent

to England and to other parts of Scotland to be woven; while the merino yarn used for the finer goods is chiefly obtained from Pleasley and Nottingham. Besides the staples, tweeds and hosiery, Hawick manufactures shawls, plaids, blankets, gloves, and leather. There are also an oil-work, for extracting oil from the soapy refuse of the fulling-mills, an iron-foundry, and a factory-engineering establishment. The population of the burgh in 1871 was 11,356; in 1879 it was estimated at about 15,000.

HAWK (Anglo-Saxon, *Hafoc*), a word of somewhat indefinite meaning, being often used to signify all diurnal Birds-of-prey which are neither Vultures nor Eagles, and again more exclusively for those of the remainder which are not Buzzards, Falcons, Harriers, or Kites. Even with this restriction it is comprehensive enough, and will include more than a hundred species, which have been arrayed in genera varying in number from a dozen to above a score, according to the fancy of the systematizer. Speaking generally, Hawks may be characterized by possessing comparatively short wings and long legs, a bill which begins to decurve directly from the cere (or soft bare skin that covers its base), and has the cutting edges of its maxilla (or upper mandible) sinuated¹ but never notched. To these may be added as characters, structurally perhaps of less value, but in other respects quite as important, that the sexes differ very greatly in size, that in most species the irides are yellow, deepening with age into orange or even red, and that the immature plumage is almost invariably more

European Sparrow-Hawk (Male and Female).

or less striped or mottled with heart-shaped spots beneath, while that of the adults is generally much barred, though the old males have in many instances the breast and belly quite free from markings. Nearly all are of small or moderate size—the largest among them being the Gos-Hawk (vol. x. p. 788) and its immediate allies, and the male of the smallest, *Accipiter tinus*, is not bigger than a Song-Thrush. They are all birds of great boldness in attacking a quarry, but if foiled in the first attempt they are apt to leave the pursuit. Thoroughly arboreal in their habits, they seek their prey, chiefly consisting of birds (though reptiles and small mammals are also taken), among trees or bushes, patiently waiting for a victim to shew itself, and gliding upon it when it appears to be unwary with a rapid swoop, clutching it in their talons, and bearing it away to eat it in some convenient spot.

It is of course impossible here to enter into details of the numerous forms which, notwithstanding the limitation

¹ In one form, *Nisoides*, which on that account has been generically separated, they are said to be perfectly straight.

above adopted, are to be called Hawks, or to describe the distinguishing characters, so far as any have been given, of the different groups or sections into which it has pleased systematic ornithologists to break them up, since hardly any two are agreed in the latter respect. There is at the outset a difference of opinion as to the scientific name which the largest and best known of these sections should bear—some authors terming it *Nisus*, and others, who seem to have the most justice on their side, *Accipiter*. In Europe there are two species—first, *A. nisus*, the common Sparrow-Hawk, which has a wide distribution from Ireland to Japan, extending also to northern India, Egypt, and Algeria, and secondly, *A. brevipes* (by some placed in the group *Micro-nisus* and by others called an *Astur*), which only appears in the south-east, and the adjoining parts of Asia Minor and Persia. In North America the place of the former is taken by two very distinct species, a small one, *A. fuscus*, usually known in Canada and the United States as the Sharp-shinned Hawk, and Stanley's or Cooper's Hawk, *A. cooperi* (by some placed in another genus, *Cooperastur*), which is larger and has not so northerly a range. In South America there are four or five more, including *A. tinus*, before mentioned as the smallest of all, while a species not much larger, *A. minullus*, together with several others of greater size, inhabits South Africa. Madagascar and its neighbouring islands have three or four species sufficiently distinct, and India has *A. badius*. A good many more forms are found in South-eastern Asia, in the Indo-Malay Archipelago, and in Australia three or four species, of which *A. cirrhocephalus* most nearly represents the Sparrow-Hawk of Europe and Northern Asia, while *A. radiatus* and *A. approximans* shew some affinity to the Gos-Hawks (*Astur*) with which they are often classed. The differences between all the forms above named and the much larger number here unnamed are such as can be only appreciated by the specialist, and could not possibly be pointed out within the limits of this article. It may be observed in conclusion that the so-called "Sparrow-Hawk" of New Zealand (*Hieracidea*) does not belong to this group of birds at all, and by many authors has been deemed akin to the Falcons. For Hawking, see FALCONRY. (A. N.)

HAWKE, EDWARD HAWKE, BARON (1705–1781), an English admiral, was the son of a barrister and was born in 1705. He entered the navy at an early age, and in 1733 became commander of the "Wolf." In the engagement off Toulon in 1744, he broke from the line of battle in order to engage the "Poder," and although he succeeded in causing her to strike her colours, his breach of discipline was punished by dismissal from the service. He was, however, almost immediately restored by the king's commands, and in 1747 was promoted to the rank of rear-admiral of the white. In October of the same year he was sent in command of a squadron intended to intercept a fleet of merchant vessels bound for the West Indies under a convoy of nine men-of-war, and coming up with them on the 14th of the month near the isle of Aix, he succeeded after a severe struggle in capturing six of the men-of-war, but darkness coming on before the close of the contest the whole of the merchant vessels escaped. For his victory Hawke was created a knight companion of the Bath. In December of the same year he was chosen member of parliament for Bristol. In May 1748 he became vice-admiral of the blue, and in January 1755 admiral of the white. In the following year he succeeded Admiral Byng as commander of the fleet in the Mediterranean, but arrived too late to succour Minorca; and in none of the commands which he subsequently held did he have an opportunity of distinguishing himself till 1759, when he took charge of a squadron sent to cruise off Brest. On the morning of the 20th November he sighted the French fleet under Admiral Conflans off Belleisle, and

notwithstanding that the French, trusting to their knowledge of the rocks and shallows, retired towards the shore, he determined to engage them, which he did with such impetuosity that their fleet was only saved from total destruction by the approach of nightfall. As it was, more than half their vessels were either disabled, captured, or driven on shore. For this brilliant victory, gained in such circumstances of difficulty and danger, with the loss of only two vessels, Hawke received the thanks of the House of Commons and a pension of £2000 per annum. In 1765 he was appointed vice-admiral of Great Britain and first lord of the admiralty. In 1776 he was raised to the peerage by the title of Baron Hawke of Towton. He died at Shepperton, Middlesex, 17th October 1781.

HAWKESWORTH, JOHN (c. 1715–1773), an author of the last century, was born in London, according to one account in 1715, but according to another in 1719. He is said to have been apprenticed first to a clockmaker and afterwards to an attorney, but at any rate he was indebted for the education requisite for the prosecution of a literary career chiefly to his own perseverance. In 1744 he succeeded Dr Johnson as compiler of the parliamentary debates for the *Gentleman's Magazine*. Eight years later he started in company with Johnson, Bathurst, and Warton a periodical called the *Adventurer*. This journal had a great success, and ran to 140 numbers, of which 70 were from the pen of Hawkesworth himself. On account of what was regarded as its powerful defence of morality and religion, Hawkesworth was rewarded by the archbishop of Canterbury with the degree of LL.D. In 1761 he published a volume of fairy tales, and an edition of Swift's works and letters, with a life prefixed which Johnson has referred to in highly laudatory terms in his *Lives of the Poets*. The reputation he obtained by these and other works was such that he was commissioned by Captain Cook to edit his papers relative to his first voyage. The work appeared in 1773 in three volumes, and as a reward of his labours Hawkesworth received from the Government the sum of £6000. His descriptions of the manners and customs of the New World were, however, regarded by many critics as hurtful to the interests of morality, and the severity of their strictures is said to have hastened his death, which took place November 17, 1773. He was buried at Bromley in Kent, where a monument has been erected to his memory. Hawkesworth was a close imitator of Johnson both in style and thought, but his independent literary talent is considerable.

HAWKINS, SIR JOHN (c. 1532–1595), was born in Plymouth about 1532, and was bred a sailor. Learning that negroes from the coast of Guinea were good merchandize for traffic in the West Indies, he made trial of this in three voyages, the first in 1562, the second in 1564. The third, made in company with young Drake in 1567, ended in disaster, the story of which is related by Hawkins himself. He was returned M.P. for Plymouth in 1572; and the next year he was made treasurer and comptroller of the navy. In the expedition against the Armada he was appointed vice-admiral, hoisting his flag on board the "Victory," and for his services on that occasion he was afterwards knighted. His last expedition (1595) was undertaken, once more with Drake, mainly with a view to rescue his son Richard, who three years before had fallen into the hands of the Spaniards off the coast of Quito. It was unsuccessful; and, worn out with fatigue and broken-hearted, he died off Puerto Rico on the 12th of November 1595. Hawkins was the first to use chain pumps and fighting nettings for ships. Stow speaks of him as a very wise, vigilant, and true-hearted man. Along with Sir Francis Drake, he founded in 1588 the "Chest at Cbatham," the forerunner of Greenwich Hospital, where

it is now preserved. A portrait of Hawkins once adorned the Armada tapestry in the House of Lords.

HAWKINS, SIR JOHN (1719–1789), will be permanently remembered as the author of an important work on the history of music. He was born March 30, 1719, in London, the son of an architect who destined his son for his own profession. Ultimately, however, Hawkins took to the law, devoting his leisure hours to his favourite study of music. A wealthy marriage in 1753 enabled him to indulge his passion for acquiring rare works of music, and he bought, for example, the collection formed by Dr Pepusit, and subsequently presented by Hawkins to the British Museum. It was on such materials that Hawkins founded his celebrated work on the *General History of the Science and Practice of Music*, in 5 vols. (republished in 2 vols., 1879). It was brought out in 1776, the same year which witnessed the appearance of the first volume of Burney's work on the same subject. The relative merits of the two works were eagerly discussed by contemporary critics. Burney no doubt is infinitely superior as a literary man, and his work accordingly comes much nearer the idea of a systematic treatise on the subject than Hawkins's, which is essentially a collection of rare and valuable pieces of music with a more or less continuous commentary. By rescuing these from oblivion Hawkins has given a permanent value to his work. Of Hawkins's literary efforts apart from music it will be sufficient to mention his occasional contributions to the *Gentleman's Magazine*, his edition of the *Complete Angler*, and his biography of Dr Johnson, with whom he was intimately acquainted. He was one of the original members of the Ivy Lane Club, and ultimately became one of Dr Johnson's executors. If there were any doubt as to his intimacy with Johnson, it would be settled by the slighting way in which Boswell refers to him. Speaking of the Ivy Lane Club, he mentions amongst the members "Mr John Hawkins, an attorney," and adds the following footnote, which at the same time may serve as a summary of the remaining facts of Hawkins's life:—"He was for several years chairman of the Middlesex justices, and upon presenting an address to the king accepted the usual offer of knighthood (1772). He is the author of a *History of Music* in five volumes in quarto. By assiduous attendance upon Johnson in his last illness he obtained the office of one of his executors,—in consequence of which the booksellers of London employed him to publish an edition of Dr Johnson's works and to write his life." Sir John Hawkins died on the 21st of May 1789, and was buried in the cloisters of Westminster Abbey.

HAWKWOOD, SIR JOHN (ob. 1394), an English adventurer who attained great wealth and renown by his services as a condottiere in the Italian wars of the 14th century. According to the accepted if not the authenticated account of his life, he was the son of a tanner of Sible Hedingham in Essex, and was apprenticed to a tailor in London. Pressed into the army, he served with honour in France, obtained the favour of the Black Prince, and received knighthood from King Edward III. On the peace of Bretigny in 1360, he collected a band of men-at-arms, and moved southward to Italy, where we find him assisting the Pisans to defeat the Florentines in 1364. His services were sought in succession by Bernabo Visconti, by the legato of Bologna, and by Pope Gregory XI. In 1375 the Florentines entered into an agreement with him, by which they were to pay him and his companion 130,000 gold florins in three months on condition that he undertook no engagement against them; and in the same year the priors of the arts and the gonfalonier decided to give him a pension of 1200 florins per annum for as long as he should remain in Italy. His subsequent services to Florence as captain-

general of the city were numerous and important. Hawkwood married Donnana, an illegitimate daughter of Bernabo Visconti, and one of his own daughters became the wife of the count of Porziglia. His latter years were spent in a villa in the neighbourhood of Florence. On his death in 1394 the republic gave him a public funeral of great magnificence and decreed the erection of a marble monument in the cathedral. This, however, was never executed; but Paolo Uccelli painted his portrait in terre-verte on the inner façade of the building, where it still remains, though damaged by removal from the plaster to canvas. Richard II. of England, probably at the instigation of Hawkwood's sons, who returned to their native country, requested the Florentines to let him remove the good knight's bones, and the Florentine Government signified its consent.

The fullest account of Sir John Hawkwood in English is in Nichol's *Bibliotheca topographica Britannica*, vol. vi. He is one of Richard Johnson's *Nine Worthies of London* (published in *Harleian Misc.*, 1808), and Fuller includes him in his *Worthies of England*. An elaborate life by Manni is given by Tartini in *Reverum Ital. Script.*; and Hawkwood is naturally treated of in Ammirato and the other Florentine chronicles. The compact with the Florentines is printed in *Archivio Storico*, 1868.

HAWTHORN (Anglo-Saxon, *haga-*, *hæg-*, or *hege-thorn*), *Cratægus*, L., a genus of plants of the natural order *Rosaceæ* and sub-order *Pomeæ*. The common hawthorn, termed also whitethorn, quickthorn, quickset, and May tree, May bush, or May (German, *Hagedorn* and *Christdorn*; French, *Aubépine*), *C. Oxyacantha*, L., is a shrub or small tree having a smooth blackish bark; numerous branches, beset usually with thorns, which represent aborted twigs; alternate, long-stalked, obovate-wedge-shaped, 3- or 5-lobed, incised or serrate smooth leaves; flowers sweet-scented, arranged in corymbs, and having caducous bracts, broad, white, pink, or scarlet petals, and 1 to 3 styles; and fruit or "haw" an oblong or nearly globular mealy pome, commonly dark red, but occasionally yellow, black, or even greenish-orange or dull white, and of 1 or 2 cells. The common hawthorn is a native of Europe as far north as 60½° in Sweden, and of North Africa, Western Asia, and Siberia, and has been naturalized in North America and Australia. It thrives best in dry soils, and in height varies from 4 or 5 to 12, 15, or, in exceptional cases, as much as between 20 and 30 feet. There are several varieties of the plant. It may be propagated from seed or from cuttings. The seeds must be from ripe fruit, and if fresh gathered should be freed from pulp by maceration in water. They germinate only in the second year after sowing; in the course of their first year the seedlings attain a height of 6 to 12 inches. In England the hawthorn has been employed for enclosure of land since the Roman occupation, but for ordinary field-hedges it is believed it was not generally in use till about the end of the 17th century. James I. of Scotland, in his *Quair*, ii. 14 (early 15th century), mentions the "hawthorn hedges knet" of Windsor Castle. The first hawthorn hedges in Scotland are said to have been planted by soldiers of Cromwell at Inch Buckling Brae in East Lothian, and Finlarig in Perthshire. On the planting and use of hawthorn fences, see *AGRICULTURE*, vol. i. pp. 296, 310. The wood of the hawthorn is white in colour, with a yellowish tinge. Fresh cut it weighs 68 lb 12 oz. per cubic foot, and dry 57 lb 3 oz. It can seldom be obtained in large portions, and has the disadvantage of being apt to warp; its great hardness, however, renders it valuable for the manufacture of various articles, such as the cogs of mill-wheels, flails and mallets, and handles of *hammers*. Both green and dry it forms excellent fuel. The bark possesses tanning properties, and in Scotland in past times yielded with ferrous sulphate a black dye for wool. The leaves are eaten by cattle, and have been employed as a substitute for tea.

Birds and deer feed upon the haws, which are used in the preparation of a fermented and highly intoxicating liquor, and for their astringency are sometimes resorted to in dysentery. The hawthorn serves as a stock for grafting other trees. As an ornamental feature in landscapes, it is worthy of notice; and the pleasing shelter it affords, and the beauty of its blossoms, have frequently been alluded to by poets. The custom of employing the flowering branches for decorative purposes on the first of May is of very early origin; but since the alteration in the calendar (see vol. iv. p. 677) the tree has rarely been in full bloom in England before the second week of that month. In Cornwall, however, in 1846, the flowers, though scarce, were gathered on the 18th April; and in the Scotch Highlands they may be seen as late as the middle of June. The hawthorn has been regarded as the emblem of hope, and its branches are stated to have been carried by the ancient Greeks in wedding processions, and to have been used by them to deck the altar of Hymen. The supposition, that the tree was the source of Christ's crown of thorns gave rise doubtless to the tradition current among the French peasantry that it utters groans and cries on Good Friday, and probably also to the old popular superstition in Great Britain and Ireland that ill-luck attended the uprooting of hawthorns. Branches of the Glastonbury thorn, *C. Oxyacantha*, var. *præcox*, which flowers both in December and in spring, were formerly highly valued in England, on account of the legend that the tree was originally the staff of Joseph of Arimathea (see GLASTONBURY, vol. x. pp. 674, 675). Sub-species of *C. Oxyacantha* are *C. monogyna*, Jacquin, and *C. oxyacanthoides*, Thuill. *C. Pyracantha* and *C. Crus-galli* are among the cultivated species of *Cratægus*.

NATHANIEL HAWTHORNE.

NATHANIEL HAWTHORNE was born at Salem, Mass., July 4, 1804. The family name, according to Julian Hawthorne, was either Hawthorne or Hathorne, the pronunciation being the same. Nathaniel preferred the name with the "w" in it. William Hawthorne, a man of restless energy and marked ability, the head of the American branch of the Hawthornes, came in 1630 from Wiltshire, England, with John Winthrop in the "Arbella," and settled in Dorchester, Mass.

In 1636 he removed to Salem, larger grants of land than he had received at Dorchester having been tendered him by that town if he would take up his residence there, on the ground that such a citizen would be "a public benefit." He justified their action by his subsequent conduct, for he cleared the woods, fought the Indians, treated with them, laid plans for the creation of a great fur company, and led adventurous expeditions into the untrodden wilderness.*

He was a Puritan of the sternest character, a "Separatist," and as magistrate ordered the whipping of Anne Coleman and four other Quakers. His son John followed in the father's footsteps, persecuting the Quakers, and presiding as chief judge in the famous Salem witch trials with great harshness and cruelty. One of the witches is reported to have invoked a heavy curse upon him and upon his children's children. Joseph Hawthorne was John's third son. He was a quiet, home-keeping farmer, while the other male members of the family were noted as sea-faring men. Joseph's son, Daniel, born in 1731, earned the name of "bold Daniel," as commander of a privateer called the "Fair America" during the Revolutionary War.

Nathaniel, the third son of Daniel, was born in 1775, and

* *Nathaniel Hawthorne and His Wife*, by Julian Hawthorne. Vol. 1, p. 10.

about the beginning of this century married Elizabeth Clarke Manning, a beautiful and gifted young lady five years his junior. "He was a silent, reserved, severe man," Julian Hawthorne says, "of an athletic and rather slender build, and habitually of a rather melancholy cast of thought." He died at the age of thirty-three, leaving three children, one of whom was Nathaniel, to the care of their mother. Madame Hawthorne came of a family as reserved and peculiar in their own way as the Hawthornes were in theirs. Both from father and mother, therefore, Nathaniel Hawthorne inherited that shy, reserved nature which was his characteristic all through life. The secluded widowhood of his mother, who lived a strict hermit to the end of her long life, or for more than forty years after Captain Hawthorne's death, and the witch-haunted memories of the quaint old town in which he was living, made a profound impression upon the young, solitary Hawthorne. At the age of seven he attended the school taught by the lexicographer, Dr. Joseph E. Worcester. During his early life he pored over the works of Spenser, Shakspeare, Pope and Milton, and devoured "The Pilgrim's Progress," "Froissart's Chronicles," and "Clarendon's History."

In August, 1820, he issued for a few weeks a little sprightly manuscript periodical, at Salem, called the *Spectator*. In 1825 he was graduated from Bowdoin College, Brunswick, Me. Among his classmates were Henry W. Longfellow, George B. Cheever, John S. C. Abbott and Horatio Bridge. Franklin Pierce, afterward President of the United States, was in the class before him. While in college he evinced no unnatural and feverish thirst for college honors. After his graduation he resided with his mother in Salem. While here he published in different periodicals occasional articles, mostly short, entertaining stories.

In 1826 he published at his own expense—\$400—"Fanshawe," an unsuccessful romance. Mr. Goodrich (Peter Parley) said it would have been successful if it had had an enterprising publisher. In 1836 he was called to Boston to edit *The American Magazine*, an illustrated periodical, on a salary of \$500 a year. Of this amount he received but little, and the magazine was soon bankrupt. Hawthorne compiled for the company publishing the magazine, a "Universal History," the foundation of the famous works of Peter Parley. His compensation was \$100.

In 1837 Hawthorne's previous contributions to "The Token," begun in 1828 by Mr. Goodrich, were published as "Twice Told Tales." Longfellow favorably reviewed the book in the *North American Review*. Attention now began to be drawn towards the author, and another series soon appeared. In 1839, the historian, Bancroft, then collector of customs at Boston, appointed him as weigher and gauger, at a salary of \$1,200. In 1841 he published the first part of "Grandfather's Chair." In 1842 he became connected for a short time with the Brook Farm experiment. In July of the same year he married Miss Sophia Peabody, who had been one of his earnest admirers, and took up his residence in an old manse at Concord on the Concord River, afterward immortalized by him in *Mosses From an Old Manse*, published in 1846. Here he devoted himself to literature, and enjoyed the friendship of Emerson, Thoreau, William Ellery Channing and other notable men.

From 1846 to 1850 he was surveyor of the port of Salem. In 1850 his most important work, *The Scarlet Letter*, was given to the world. From 1850 to 1852 he lived in Lenox, Mass., and published in 1851 the *House of Seven Gables*, and in 1852 the *Blithedale Romance*. In the latter part of the same year he wrote a life of Franklin Pierce, then the Democratic candidate for the presidency. Hawthorne wrote it, declaring he would accept no office in case Mr. Pierce were elected. Urgent friends overcame his scruples, and he served as United States consul at Liverpool, England, from 1853 to 1857.

In 1851 he published *True Stories from History*, etc., and *The Wonder Book*, which were followed by *The Snow Image* (1852), *Tanglewood Tales* (1853), *The Marble Faun* (1860, in some particulars his best effort), *Our Old Home* (1863), and *English Note-Books*.

From 1860 to 1864 he lived in Concord, Mass., and died while journeying for his health, at Plymouth, N. H., May 19, 1864. After his death were published a series of *Notebooks* (1868-1872), *Septimius Felton* (1872), and portions of the unfinished *Dolliver Romance*.

There would appear, on a slight view of the matter, no reason for the little notice which Hawthorne's early productions received. The subjects were mostly drawn from the traditions and written records of New England, and gave the "beautiful strangeness" of imagination to objects, incidents and characters which were familiar facts in the popular mind. The style, while it had a purity, sweetness and grace which satisfied the most fastidious and exacting taste, had at the same time more than the simplicity and clearness of an ordinary school-book. But though the subjects and the style were thus popular, there was something in the shaping and informing spirit which failed to awaken interest, or awakened interest without exciting delight. Misanthropy, when it has its source in passion,—when it is fierce, bitter, fiery, and scornful,—when it vigorously echoes the aggressive discontent of the world, and furiously tramples on the institutions and the men luckily rather than rightfully in the ascendant,—this is always popular; but a misanthropy which springs from insight,—a misanthropy which is lounging, languid, sad and depressing,—a misanthropy which remorselessly looks through cursing misanthropes and chirping men of the world with the same sure detecting glance of reason,—a misanthropy which has no fanaticism, and which casts the same ominous doubt on subjectively morbid as on subjectively moral action,—a misanthropy which has no respect for impulses, but has a terrible perception of spiritual laws,—this is a misanthropy which can expect no wide recognition; and it would be vain to deny that traces of this kind of misanthropy are to be found in Hawthorne's earlier, and are not altogether absent from his later, works. He had spiritual insight, but it did not penetrate to the sources of spiritual joy; and his deepest glimpses of truth were calculated rather to sadden than to inspire. A blandly cynical distrust of human nature was the result of his most piercing glances into the human soul. He had humor, and sometimes humor of a delicious kind; but this sunshine of the soul was but sunshine breaking through or lighting up a sombre and ominous cloud. There was also observable in his earlier stories a lack of vigor, as if the power of his nature had been impaired by the very process which gave depth and excursiveness to his mental vision. Throughout, the impression is conveyed of a shy recluse, alternately bashful in disposition and bold in thought, gifted with original and various capacities, but capacities which seemed to have developed themselves in the shade, without sufficient energy of will or desire to force them, except fitfully, into the sunlight. Shakspeare calls moonlight sunlight *sick*; and it is in some such moonlight of the mind that the genius of Hawthorne found its first expression. A mild melancholy, sometimes deepening into gloom, sometimes brightened into a "humorous sadness," characterized his early creations. Like his own Hepzibah Pyncheon, he appeared to be "walking in a dream;" or rather, the life and reality assumed by his emotions "made all outward occurrences unsubstantial, like the teasing phantasms of an unconscious slumber." Though dealing largely in description, and with the most accurate perceptions of outward objects, he still, to use again his own words, gives the impression of a man "chiefly accustomed to look inward, and to whom external matters are of little value or import, unless they bear relation to something within his own mind." As psychological portraits of morbid natures, his delineations of character might have given a purely intellectual satisfaction; but there was audible, to the delicate ear, a faint and muffled growl of personal discontent, which showed they were not mere exercises of penetrating, imaginative analysis, but had in them the morbid vitality of a despondent mood.

Many of the stories in *Twice Told Tales* are at once a representation of early New England life and a criticism on it. They have much of the deepest truth of history in them. *The Legends of the Province House*, *The Gray Champion*, *The Gentle*

Boy, The Minister's Black Veil, Endicott and the Red Cross, not to mention others, contain important matter which cannot be found in Bancroft or Grahame. They exhibit the inward struggles of New England men and women with some of the darkest problems of existence, and have more vital import to thoughtful minds than the records of Indian or revolutionary warfare. In the *Prophetic Pictures, Fanci's Show Box, The Great Carbuncle, The Haunted Mind*, and *Edward Fane's Rose Bud*, there are flashes of moral insight which light up for the moment, the darkest recesses of the individual mind; and few sermons reach to the depth of thought and sentiment from which these seemingly airy sketches draw their sombre life. Interspersed with serious histories and moralities like these are others which embody the sweet and playful, though still thoughtful and slightly saturnine action of Hawthorne's mind,—like *The Seven Vagabonds, Snow-Flakes, The Lily's Quest, Mr Higginbotham's Catastrophe, Little Annie's Ramble, Sights from a Steeple, Sunday at Home*, and *A Rill from the Town Pump*.

The *Mosses From an Old Manse* are intellectually and artistically an advance from the *Twice Told Tales*. The twenty-three stories which make up the volumes are almost perfect of their kind. In description, narration, allegory, humor, reason, fancy, subtlety, inventiveness, they exceed the best productions of Addison; but they want Addison's sensuous contentment and sweet and kindly spirit.

The author throughout this work is evidently more interested in his large, wide, deep, indolently serene and lazily sure and critical view of the conflict of ideas and passions than he is with the individuals who embody them. He shows moral insight without moral earnestness. He cannot contract his mind to the patient delineation of a moral individual, but attempts to use individuals in order to express the last results of patient moral perception. Young Goodman Brown and Roger Malvin are not persons; they are the mere loose, personal expression of subtle thinking. *The Celestial Railroad, The Procession of Life, Earth's Holocaust, The Bosom Serpent*, indicate thought of a character equally deep, delicate and comprehensive, but the characters are ghosts of men rather than substantial individualities. In the *Mosses from an Old Manse*, we are really studying the phenomena of human nature, while for the time we beguile ourselves into the belief that we are following the fortunes of individual natures.

In the romance of *The Scarlet Letter* he first made his genius efficient by penetrating it with passion.

Two characteristics of Hawthorne's genius stand plainly out in the conduct and characterization of the romance of *The Scarlet Letter* which were less obviously prominent in his previous works. The first relates to his subordination of external incidents to inward events. Even his most picturesque descriptions and narratives are only one-tenth matter to nine-tenths spirit. The results that follow from one external act of folly or crime are to him enough for an Iliad of woes.

The second characteristic of his genius is connected with the first. With his insight of individual souls he combines a far deeper insight of the spiritual laws which govern the strangest aberrations of individual souls. But it seems to us that his mental eye, keen-sighted and far-sighted as it is, overlooks the merciful modifications of the austere code whose pitiless action it so clearly discerns. In his long and patient brooding over the spiritual phenomena of Puritan life, it is apparent to the least critical observer, that he has imbibed a deep personal antipathy to the Puritanic ideal of character; but it is no less apparent that his intellect and imagination have been strangely fascinated by the Puritanic idea of justice. His brain has been subtly infected by the Puritanic perception of Law, without being warmed by the Puritanic faith in Grace.

The House of the Seven Gables, Hawthorne's next work, while it has less concentration of passion and tension of mind than *The Scarlet Letter*, includes a wider range of observation, reflection and character; and the morality, dreadful as fate, which hung like a black cloud over the personages of the previous story, is exhibited in more relief.

In the delicious stories of *The Wonder Book and Tanglewood Tales* Hawthorne's genius distinctly appears in its most lovable though not in its deepest forms. *The Blithedale Romance* very much better than these illustrates the operation, indicates the

quality, and expresses the power of the author's genius. In regard to *The Marble Faun* there is room for widely varying opinions. Hilda, Miriam and Donatello will be generally received as superior in power and depth to any of Hawthorne's previous creations of characters. Donatello especially must be considered one of the most original and exquisite conceptions in the whole range of romance.

Our Old Home and *The English Note-Books* reveal the true artist in the author. His pen and ink portraits are drawn with unrivaled power in that English which was absolutely unique. We find in these sketches or impressions always the best work in the best place. The language is pellucid as crystal, full of delicate and varied music, with gleams of poetry, and touches of that peculiar humor of his, which is half senile and half light. In summing up these brief accounts of Hawthorne's works we may say that in intellect and imagination, in the faculty of discerning spirits and detecting laws he has had no equal among the novelists of the century. His genius, by the seemingly irresistible force of heredity, was drawn towards the dark paths of the soul, haunted by shadowy shapes of gloom and mystery. George S. Hillard once asked him to write a story which should be cheerful and sunny from beginning to end. He smiled and replied that it was impossible, that the dark cloud would come over the sun, that the spectral form would glide in and hush the noise of mirth. This tendency prevented him from winning that hold upon the great mass of the people which he otherwise would have obtained.

[See *Nathaniel Hawthorne and His Works*, by Julian Hawthorne; *The English Note-Books of Nathaniel Hawthorne*, by G. S. Hillard, *Atlantic Monthly*, June, 1870.]

(L. P. W.) (S. P.)

HAXTHAUSEN. AUGUST FRANZ EDUARD MARIA VON (1792–1867), baron of Haxthausen-Abbenbürg, was born on his father's estate near Paderborn in Westphalia, February 3, 1792. Educated at first at home, he proceeded in 1811 to the school of mining at Klausthal in the Harz, and after serving in the Hanoverian army in 1813–15, entered the university of Göttingen. On finishing his course there in 1818, he occupied himself with the management of his estates, and the study of the land laws and the legal rights of the peasantry. The result of his studies appeared in 1829 in *Die Agrarverfassung und ihre Constitute*, a work which attracted much attention, and procured for him an official commission to investigate and report upon the land laws of the Prussian provinces with a view to a new code. After nine years spent in laborious collation, he published in 1839 an exhaustive treatise, *Die ländliche Verfassung in den Provinzen Ost- und West-Preussen*. In 1843–44, at the request of the emperor Nicholas, he undertook a similar labour for Russia. The fruits of his investigations in that country are contained in *Studien über die inneren Zustände, das Volksleben, und insbesondere die ländlichen Einrichtungen Russlands* (3 vols. 1847–52), in *Die Kriegsmacht Russlands* (1852), and in *Die ländliche Verfassung Russlands* (1866). In 1836 he received the honorary title of privy state-councillor, and afterwards of hereditary chamberlain of the principality of Paderborn. In 1847–48 he sat as a member of the combined diet at Berlin, and afterwards of the first Prussian chamber. After travelling through a large part of Europe, Baron Haxthausen retired to his estate. He died at Hanover, January 1, 1867.

Besides the foregoing works, Haxthausen was the author of *The Algerian Slave*, a novel; and *Transcaucasia, Sketches of the Nations and Raees between the Black Sea and the Caspian*, in English, 1854, Germān, 1856; in 1864 he edited *Das Constitutionelle Princip*, a collection of political writings by various authors.

HAYDN, JOSEPH (1732–1809), one of the most celebrated composers of the 18th century, was born at Rohrau, a village in Lower Austria, March 31, 1732. Schindler relates that when Beethoven, not long before his death, received a picture of Haydn's birthplace, he exclaimed—"How wonderful that so great a man should have been born in a peasant's cottage." This cottage, which is still standing, had been built by Haydn's father, a worthy wheelwright, of whose twelve children the composer was

the second. At an early age the child evinced so decided a talent for music that one Johann Mathias Frankh, a distant relation of the family, proposed to undertake his musical and general education, and for that purpose invited him to Hainburg, a neighbouring town where Frankh kept a school. To Hainburg accordingly young Haydn went in 1738, and there he received instruction in the elementary knowledge of his art, including a practical acquaintance with most instruments, at the hands of the musical schoolmaster. Having developed an agreeable soprano voice, young Haydn was by the intercession of the dean of Hainburg promoted to a post amongst the choir boys of St Stephen's cathedral, Vienna, where he remained from 1740-50, doing duty in the church services, and at the same time enlarging his musical knowledge and experience. His artistic education was, however, all but exclusively practical, and it is said that he received only two theoretical lessons from Reuter the chapel-master. As a composer, therefore, Haydn was in every sense self-taught. Of his zeal in acquiring information he was in the habit of talking with pride in later years, and several works of sacred music were the first fruit of his early studies. In 1749 or 1750 his beautiful boyish voice changed, and he lost his position accordingly. Being now thrown on his own resources, he had to undergo various forms of musical drudgery, such as giving lessons (at the moderate stipend of two florins per month) and even playing in the orchestra at dances and the like. His condition was somewhat improved by his acquaintance with Metastasio, the celebrated operatic poet, in fact the Scribe of the 18th century, who introduced him to Señor Martinez, a Spaniard living in Vienna, whose daughter Haydn instructed for several years. It was through Metastasio also that Haydn came into contact with Porpora the composer, best known as the singing-master of the great Farinelli. For a considerable time Haydn remained in constant intercourse with him, acting as his accompanist, and occasionally it is said as his valet. In return he obtained a perfect acquaintance with Porpora's method, besides his knowledge of the Italian language, both invaluable to a composer in those days. The works of Emmanuel Bach, son of the great Sebastian, at the same time became his model for chamber music. Fux's excellent work *Gradus ad Parnassum* was his guide in his studies of counterpoint. A mass in F, and a farce *Der neue krumme Teufel*, both written in or about 1752, were Haydn's first important attempts at composition. The former is still in existence, but of the latter the libretto by Kurz only remains. It was produced early in 1752, and seems to have met with considerable success. Haydn's acquaintance with Gluck also dates from this period. An important event in Haydn's life was his acquaintance with Baron Fürberg, an accomplished amateur, for whose private concerts he wrote his first string quartet, a form of composition in which he earned some of his greatest and most permanent triumphs. It is in the key of B flat, and was followed in rapid succession by seventeen other works of the same class, written during the years 1755 and 1756. To his new protector Haydn also owed his still more important acquaintance with Count Ferdinand Morzin. Count Morzin in 1759 appointed him conductor of his small but excellent band. The opportunities of hearing his own works performed by competent musicians Haydn did not neglect, and his first symphony in D belongs to the year 1759. Soon afterwards Count Morzin was compelled to dissolve his band, but Haydn's position was by this time sufficiently established, and very soon afterwards he found employment as second chapel-master to Prince Paul Esterhazy, one of the richest Austrian nobles, whose love of art was as great as his wealth. The Esterhazy family have been amongst the foremost patrons of music in Vienna from the days of Haydn to those of Beethoven and Schubert. Prince Paul

died in 1762, and left his title and fortune to his brother Nicholas, surnamed the Magnificent. He immediately enlarged his orchestra, and also increased the salaries of its members, including that of Haydn (from 400 to 600 florins), and on the death of his colleague Werner, a scholarly but dry musician, appointed him first conductor. This position, or at least its title and emoluments, Haydn retained till his death, and his attachment to the Esterhazy family remained unchanged by his subsequent fame and fortunes. The events just referred to determined Haydn's career for the next twenty-eight years. During this period he was in the active service of his protector, residing at Esterházy, the splendid country seat of the family, described as a second Versailles, or in Vienna, conducting the orchestra of the prince, and writing for his concerts and theatre a number of works, including symphonies, cassationes, quartets, sonatas, and numerous vocal compositions, including several operas, none of which, however, had any permanent success. Thus the opera *La vera Costanza*, written for the court theatre of Vienna in 1776, was withdrawn by the composer owing to intrigues against him, it is said; and we are not told that it met with a much better fate on its revival fourteen years later. Another dramatic work, *Isola disabitata* (1779), procured for the composer the membership of the Accademia Filarmonica at Modena, and a gold snuff-box from the king of Spain. But with its companions it has not escaped oblivion. The truth is that Haydn was without the true dramatic spirit, and of this he was himself well aware. According to his own confession his operas were fitted only for the small stage at Esterházy; in a large theatre, and before a miscellaneous audience, they lost their effect. The scores of most of the operas are preserved in the archives of Eisenstadt, another seat of the Esterhazy family. Of his life during this period little need be said. It was eventless and to a certain extent monotonous, but free from care and exclusively devoted to art. His own words, quoted by Herr Pohl, sum up all that it is necessary to relate. "My prince was always satisfied with my work; I not only had the encouragement of constant approval, but as conductor of an orchestra I could make experiments, observe what produced an effect and what weakened it, and was thus in a position to improve, alter, make additions or omissions, and be as bold as I pleased. I was cut off from the world; there was no one to confuse or torment me, and I was forced to become original." The only person that could have wished to "confuse or torment" the harmless composer was fortunately kept at distance by the strict order of the prince's household, that none of his musicians was to be accompanied by his wife. Haydn at an early age became attached to the daughter of a hairdresser, Keller by name, and after her death was persuaded to marry her sister, three years older than himself. The marriage was an unhappy one, and the pair separated soon after their union, Haydn's inflammable heart subsequently causing him more or less serious trouble on more than one occasion. In the meantime the composer's fame had begun to spread from an early period of his career. As early as 1766 a journal speaks of him as the "favourite of the nation," and foreign countries were not slow in acknowledging his merits. Thus one of his works, *The Seven Words of our Saviour on the Cross*, a series of orchestral interludes for the church service on Good Friday, was written by special invitation for the cathedral of Cadiz. In Paris his works were performed with immense success at the Concert Spirituel, and a single English firm bought the copyright of no less than 129 of his works, including 82 symphonies. The appreciation of Haydn's work in England led to important results in his latter years. Several pressing invitations to visit that country had been declined by the composer on account

of his services being required at Esterházy. But when in 1790 Prince Nicholas died, and his successor dissolved the orchestra, allowing Haydn a considerable pension, the latter was at last at liberty to accept a munificent offer from Salomon, the violinist and entrepreneur, in whose company he started for London, where Salomon occupied a leading position in the musical world. They left Vienna in December 1790, and travelled by way of Bonn, where Salomon had been born. There, accordingly, a halt was made, and Haydn was received by the elector with every honour due to his fame. The amusing description of a dinner given during his stay at Bonn may be read in Thayer's biography of Beethoven, who at that time was a member of the electoral chapel, and not unlikely made on this occasion Haydn's acquaintance. On the latter's return journey the young man submitted a cantata to the celebrated composer, whom he soon afterwards followed to Vienna to become his pupil. It is well known that the relations between the great master and his greater pupil were not altogether what might have been desired. Beethoven's genius was of too individual a type to bear the impress of a nature so different as Haydn's, and the latter may not always have taken sufficient trouble to enter into the ways of his wilful pupil. Certain it is that, at one time of his career, Beethoven delighted in speaking slightly of "Papa Haydn," and, for instance, refused to call himself Haydn's pupil, because, as he bluntly said, he never learnt anything under his tuition. He even went so far as to suspect Haydn of wilfully trying to keep him back in his studies. It was only in his later years that this animosity gave way to the more genial appreciation of his great predecessor, an expression of which is quoted at the beginning of this notice.

Haydn's visit to London was a succession of triumphs. Dr Burney welcomed him with a laudatory poem; the various musical societies of the metropolis vied for his presence; and on July 8, 1791, he was created doctor of music by the university of Oxford. At court also he was received with every distinction, and the aristocracy followed the royal example. Neither were more substantial rewards wanting. Haydn's engagement with Salomon was to write and conduct at the concerts in the Hanover Square Rooms six symphonies, and the success of these may be judged from the fact that at Haydn's benefit concert, for which £200 had been guaranteed to him, the receipts rose to £350. He also appeared at other concerts (one given by himself at Hanover Square Rooms, where amongst other works the *Seven Words* already referred to was performed), always with equal success. The same events were repeated in the following year, when the Salomon concerts began in February, and concluded with an extra concert in June. The symphonies known as the "Salomon Set," comprising some of Haydn's finest instrumental works, are the permanent record of the connexion of the two artists. In 1792 Haydn also went to hear the charity children at St Paul's, whose singing produced on him as deep an impression as it did on Berlioz many years later. "I was more touched by this innocent and reverent music," he wrote in his diary, "than by any I ever heard in my life." Haydn left London in June 1792, but only to return in January 1794. In addition to his earlier works six new symphonies were played at the concerts of Salomon, which in the following year were given at the King's Concert-room and terminated on June 1, 1795, when Haydn appeared for the last time in England. In addition to valuable presents from royalty and other persons, he realized £1200 by his second English visit, from which he returned to Vienna in the autumn of 1795, to resume once more his functions in the newly organized chapel of Prince Esterházy. He was now well stricken in years, and might have rested on his laurels. But so far from this being the case, the two works on

which—apart from his symphonies and sonatas—his immortality must mainly rest, belong to this last epoch of his life. These were the oratorio *The Creation*, and the cantata *The Seasons*. They were both written to German translations of English libretti, the former being compiled from *Paradise Lost*, the latter from Thomson's *Seasons*. *The Creation* was first performed in public on March 19, 1799, when its success was as immediate as it has since proved permanent. *The Seasons* was begun soon after the completion of *The Creation*, and finished in very little time. No one, delighted by the charm and spontaneity of its melodies, would suspect it to be the work of a feeble old man. Such, however, Haydn had now become. He wrote little after *The Seasons*, and his public appearances were few and far between. His old age was surrounded by the love of his friends and the esteem of the musical world, but his failing health did not admit of much active enjoyment. He was seen in public for the last time at a performance of *The Creation* in 1808. But his own music made so overpowering an impression on him that he had to be carried out of the hall. He died on May 31, 1809, during the occupation of Vienna by Napoleon's army, and many French officers followed his body to the grave.

Haydn's compositions comprize almost every form of vocal and instrumental music. Of his dramatic works the operas are of infinitely less importance than *The Creation* and *The Seasons*. In the former there are points of grand and truly epic conception, surpassed by few masters except Handel, and the idyllic charm of the latter is as fresh to-day as it was eighty years ago. At the same time the great importance of Haydn in the history of music lies elsewhere. It was as an instrumental composer that he opened a new epoch of musical development. That amongst his 125 orchestral symphonies there are many extremely slight efforts is a matter of course. Even his finest symphonies, such as the celebrated *Surprise*, or the one in E flat surnamed in Germany "mit dem Paukenwirbel," on account of the characteristic drum-roll occurring in it, are pigmies if compared with Beethoven's colossal efforts. At the same time it is true that without Haydn's modest substruction Beethoven's mighty edifice would have been impossible. It was Haydn who first fixed the form of the symphony and gave it consistency of development. The lucid and harmonious treatment of his themes and the symmetrical structure of his symphonic movements remain still unsurpassed. And the same may be said in almost the same words of his string quartets, of which he wrote no less than eighty-three. It is by such works as these that Haydn has earned the name of father of instrumental music, generally and justly applied to him. At the same time it cannot be denied that there is in his works a certain want of intensity and depth. He avoids the high places of thought and passion; his path lies mostly in the smiling plains of humour and agreeable sentiment. In the former especially he excels, and it ought to be noted that his humour is of that peculiarly Viennese type which is as harmless as it is charming, and to the genial influence of which even such serious composers as Beethoven and Brahms have had to submit. Some of Haydn's minuets especially seem to spring immediately from the consciousness of the people. How much he was at one with his nation is further proved by such a song as his "Gott erhalte Franz den Kaiser," which has become the Austrian national hymn, and is one of the rare instances in which a genuine folksied can be traced to a celebrated composer,—for generally the songs of the people are produced by the people. To sum up, Haydn's place in the history of his art will remain unassailed by all the changes musical taste has undergone since his time, or may still undergo. His melodies, though simple, are genuinely inspired, and will never lose their

charm; and his workmanship will remain an invaluable model of clearness and symmetry. Haydn's life has been written by many pens and in many languages, Stendhal, the celebrated novelist, being amongst his French biographers. But all these earlier attempts have been thrown into the shade by the excellent works of Herr C. F. Pohl (*Mozart and Haydn in London*, 1867; *Joseph Haydn*, vol. i., 1875; and the article "Haydn" in *Grove's Dictionary of Music and Musicians*), which are full of accurate and comprehensive research. To Herr Pohl all students of Haydn's life must confess themselves deeply indebted.

Two of Haydn's brothers acquired a certain amount of celebrity. JOHN MICHAEL HAYDN, born at Rohrau, September 14, 1737, and like his brother a choir-boy at St Stephen's cathedral, became a prolific and able composer of masses and all kinds of church music. He lived during the greater part of his life at Salzburg, and his name is frequently mentioned in the biography of Mozart. Of his numerous compositions few have been printed. A mass in D is perhaps his masterpiece. He died August 10, 1806. The youngest brother, JOHANN HAYDN (born December 23, 1743, died May 20, 1805), had some reputation as a vocalist, and became, most probably by his brother's intercession, a singer in Prince Esterhazy's chapel. (F. H.)

HAYDON, BENJAMIN ROBERT (1786-1846), historical painter and writer, was born at Plymouth, January 26, 1786. His mother was the daughter of the Rev. Benjamin Copley, rector of Dodbrook, Devon, whose son, General Sir Thomas Copley, signalized himself in the Russian service at the siege of Ismail. His father, a prosperous printer, stationer, and publisher, was a man of literary taste, and was well known and esteemed amongst all classes in Plymouth. Haydon, an only son, at an early date gave evidence of his taste for study, which was carefully fostered and promoted by his mother. At the age of six he was placed in Plymouth grammar school, and at twelve in Plympton St Mary school. He completed his education in this institution, where Sir Joshua Reynolds also had acquired all the scholastic training he ever received. On the ceiling of the school-room was a sketch by Reynolds in burnt cork, which it used to be Haydon's delight to sit and contemplate. Whilst at school he had some thought of adopting the medical profession, but he was so shocked at the sight of an operation that he gave up the idea. A perusal of Albinus, however, inspired him with a love for anatomy; and Reynolds's discourses aroused within him a smouldering taste for painting, which from childhood had been the absorbing idea of his mind. Sanguine of success, full of energy and vigour, he started from the parental roof, May 14, 1804, for London, and entered his name as a student of the Royal Academy. He began and prosecuted his studies with such unwearied ardour that Fuseli wondered when he ever found time to eat. At the age of twenty-one (1807) Haydon exhibited, for the first time, at the Royal Academy, *The Repose in Egypt*, which was bought by Mr Thomas Hope the year after. This was a good start for the young artist, who shortly received a commission from Lord Mulgrave and an introduction to Sir George Beaumont. In 1809 he finished his well-known picture of *Dentatus*, which, though it brought him a great increase of fame, involved him in a life-long quarrel with the Royal Academy, whose committee had hung the picture in a small side-room instead of the great hall. In 1810 his difficulties began through the stoppage of an allowance of £200 a year he had received from his father. His disappointment was embittered by the controversies in which he now became involved with Sir George Beaumont, for whom he had painted his famous picture of *Macbeth*, and Mr Payne Knight, who had denied the beauties as well as the value of the *Elgin Marbles*. *The Judgment of Solomon*, his next

production, gained him £700, besides £100 voted to him by the directors of the British Institution, and the freedom of the borough of Plymouth. To recruit his health and escape for a time from the cares of London life, Haydon joined his intimate friend Wilkie in a trip to Paris; he studied at the Louvre; and on his return to England produced his *Christ's Entry into Jerusalem*, which afterwards formed the nucleus for the American Gallery of Painting, which was erected by his cousin John Havilland of Philadelphia. Whilst painting Lazarus his pecuniary difficulties increased, and for the first time he was arrested but not imprisoned, the sheriff-officer taking his word for his appearance. Amidst all these harassing cares he married in October 1821 a beautiful young widow, Mrs Hyman, to whom he was devotedly attached. In 1823 Haydon was lodged in the King's Bench, where he received consoling letters from the first men of the day. Whilst a prisoner he drew up a petition to parliament in favour of the appointment of "a committee to inquire into the state of encouragement of historical painting," which was presented by Mr Brougham. He also, during a second imprisonment in 1827, produced the picture of the *Mock Election*, the idea of which had been suggested by an incident that happened in the prison. The king (George IV.) gave him £500 for this work. Among Haydon's other pictures were—1829, *Eucles*, and *Punch*; 1831, *Napoleon at St Helena*, for Sir Robert Peel; *Xenophon*, on his Retreat with the "Ten Thousand," first seeing the Sea; and *Waiting for the Times*, purchased by the marquis of Stafford; 1832, *Falstaff*, and *Achilles playing the Lyre*. In 1834 he completed the *Reform Banquet*, for Lord Grey—this painting contained 197 portraits; in 1843, *Curius Leaping into the Gulf*, and *Uriel and Satan*. When the competition took place at Westminster Hall, Haydon sent two cartoons, *The Curse of Adam*, and *Edward the Black Prince*, but had not the good fortune to gain a prize for either. He then painted *The Banishment of Aristides*, which was exhibited with other productions under the same roof where Tom Thumb was then making his debut in London. The exhibition was unsuccessful; and the artist's difficulties increased to such an extent that, whilst employed on his last grand effort, *Alfred and the Trial by Jury*, overcome by debt, disappointment, and ingratitude, he wrote "Stretch me no longer on this rough world," and put an end to his existence with a pistol-shot, June 22, 1846, in the sixty-first year of his age. He left a widow and three children (various others had died), who, by the generosity of their father's friends, were rescued from their pecuniary difficulties and comfortably provided for; amongst the foremost of these friends were Sir Robert Peel, Count D'Orsay, Mr Justice Talfourd, and Lord Carlisle.

Haydon began his first lecture on painting and design in 1835, and afterwards visited all the principal towns in England and Scotland. His delivery was energetic and imposing, his language powerful, flowing, and apt, and replete with wit and humour; and to look at the lecturer, excited by his subject, one could scarcely fancy him a man overwhelmed with difficulties and anxieties. The height of Haydon's ambition was to behold the first buildings of his country adorned with historical representations of her glory. He lived to see the acknowledgment of his principles by Government in the establishment of schools of design, and the embellishment of the new houses of parliament; but in the competition of artists for the carrying out of this object, the commissioners (amongst whom was one of his former pupils) considered, or affected to consider, that he had failed. Haydon was well versed in all points of his profession; and his *Lectures*, which were published shortly after their delivery, showed that he was as bold a writer as painter. It may be mentioned in this

connexion that he was the author of the long and elaborate article, "Painting," in the 7th edition of the *Encyclopædia Britannica*.

To form a correct estimate of Haydon it is necessary to read his autobiography. This is one of the most natural books ever written, full of various and abundant power, and fascinating to the reader. The author seems to have daguerre-typed his feelings and sentiments without restraint as they rose in his mind, and his portrait stands in these volumes limned to the life by his own hand. His love for his art was both a passion and a principle. He found patrons difficult to manage; and, not having the tact to lead them gently, he tried to drive them fiercely. He failed, abused patrons and patronage, and intermingled talk of the noblest independence with acts not always dignified. He was self-willed to perversity, but his perseverance was such as is seldom associated with so much vehemence and passion. With a large fund of genuine self-reliance he combined a considerable measure of vanity. To the last he believed in his own powers and in the ultimate triumph of art. In taste he was deficient, at least as concerned himself. Hence the tone of self-assertion which he assumed in his advertisements, catalogues, and other appeals to the public. He proclaimed himself the apostle and martyr of high art, and believed himself to have on that account a claim on the sympathy and support of the nation. It must be confessed that he often tested severely those whom he called his friends. Every reader of his autobiography will be struck at the frequency and fervour of the short prayers interspersed throughout the work. Haydon had an overwhelming sense of a personal, overruling, and merciful providence, which influenced his relations with his family, and to some extent with the world. His conduct as a husband and father entitles him to the utmost sympathy. In art his powers and attainments were undoubtedly very great, although his actual performances mostly fall short of the faculty which was manifestly within him; his general range and force of mind were also most remarkable, and would have qualified him to shine in almost any path of intellectual exertion or of practical work. His eager and combative character was partly his enemy; but he had other enemies actuated by motives as unworthy as his own were always high-pitched and on abstract grounds laudable. Of his three great works—the Solomon, the Entry into Jerusalem, and the Lazarus—the second has generally been regarded as the finest. The Solomon is also a very admirable production, showing his executive power at its leftiest, and of itself enough to place Haydon at the head of British historical painting in his own time. The Lazarus, now in the National Gallery, is a more unequal performance, and in various respects open to criticism and censure; yet the head of Lazarus is so majestic and impressive that, if its author had done nothing else, we must still pronounce him a potent pictorial genius.

The chief authorities for the life of Haydon are *Life of B. R. Haydon, from his Autobiography and Journals*, edited and compiled by Tom Taylor, 3 vols., 1853; and *B. R. Haydon's Correspondence and Table Talk*, with a memoir by his son, F. W. Haydon, 2 vols., 1876. (W. M. R.)

HAY FEVER, HAY ASTHMA, or SUMMER CATARRH, a term applied to a catarrhal affection of the respiratory mucous membrane occurring in some individuals during the hay season, and generally believed to be due to the inhalation of the emanations from the spring grass (*Anthoxanthum odoratum*). It is an ailment of comparatively rare occurrence. The symptoms are those commonly experienced in the case of a severe cold or influenza, consisting of headache, violent sneezing, and watery discharge from the nostrils and eyes, together with dry hard cough, and occasionally severe asthmatic paroxysms. The attack usually runs a course of from two to six weeks, unless cut

short by appropriate treatment, to which the complaint is in a considerable measure amenable. There is generally an annual recurrence of the disorder in those liable to it if they are exposed to its exciting cause, namely, the presence of hay. Symptoms of a similar character are produced in certain persons by the aroma of various flowers, by ipecacuan, and by the odour from cats, dogs, and rabbits. All such cases are examples of idiosyncrasy, and the individual is in general permanently susceptible to the influence of the excitant. In not a few instances an hereditary liability is traceable. The most effectual method of treatment in hay fever is to avoid the exciting cause, namely, the neighbourhood of grass fields, during the particular season. Removal to the seaside often succeeds in putting an end to an attack, and many persons who are liable to the complaint make such a change annually before its expected onset, and thus escape. For those who are unable to accomplish this, and must remain exposed to the noxious emanation, the use of a respirator is recommended. Of medicinal agents for affording relief during an attack, the usual remedies for asthma may be advantageously resorted to (see *ASTHMA*), while the use of the nasal douche with a weak solution of quinine and the employment of creosote or carbolic acid inhalations have been suggested.

HAYLEY, WILLIAM (1745–1820), the friend and biographer of Cowper, and grandson of William Hayley, dean of Chichester, was born in that city on the 9th November 1745. On account of mismanagement during a fever which he had while in a boarding school at Kingston, he was reduced to such prostration that the preservation of his life appeared to present only the promise of hopeless lameness and idiocy, but by careful nursing his health was gradually completely restored, and after some years' private tuition he pursued his studies at Eton and at Trinity College, Cambridge. In 1766 he procured a certificate of admission to the Middle Temple, London, but a short trial of legal studies was sufficient to dissipate the unexperienced preference which he had cherished for the profession of law. After his marriage in 1769 he stayed for some years chiefly in London, but in 1774 he retired to his patrimonial estate of Eartham in Sussex, resolved to spend the remainder of his days in rural quiet, with only such an amount of literary activity as might defy ennui and give a zest to life. Hayley made more than one attempt to succeed as a dramatic author, but first won fame by his poetical *Essays on Painting, History, and Epic Poetry*, and by his poem the *Triumph of Temper*. The success of these poems was partly attributable to the general dearth of poetic talent at the time, but they had also certain external qualities fitted to secure for them at least a temporary popularity; and his notes to his poetical essays also displayed very extensive reading, and exerted considerable influence in directing attention in England to the literature of Italy and Spain. On the death of Warton, Hayley was offered the laureateship, but declined it. In 1792 he made the acquaintance of the poet Cowper; and this acquaintance ripened into a friendship which remained unbroken until Cowper's death in 1800. This bereavement was separated by only a week from that caused by the death of Hayley's natural son Thomas Alphonso, who had given great promise of excellence as a sculptor; and, shrinking from the associations now connected with Eartham, Hayley retired to what he called a "marine hermitage," which he had built at Feltham, and there resided till his death, November 20, 1820. Besides the *Life of Cowper*, published in 1803, Hayley was the author of a number of works in prose, which were not, however, so successful as his early poetical productions. Indeed the estimation in which he was held even during his lifetime depended perhaps more on his acquirements and widely-cultivated tastes and his position

in society than on his achievements in literature. The *Memoirs of Hayley*, 2 vols., for writing which, to be published posthumously, he received a considerable allowance during the last twelve years of his life, appeared in 1823.

HAYNE, ROBERT YOUNG (1791-1840), American statesman, was born in St Paul's parish, Colleton district, South Carolina, on November 10, 1791. He studied law at Charleston, S. C., and in his twenty-first year was admitted to the bar there, but in the same year (1812) served for a short time as a soldier in the war with Great Britain. Returning to practise in Charleston, Hayne was elected a member of the State legislature in 1814, and four years later became speaker. Shortly afterwards he accepted the post of attorney-general for his native State, though he declined the same office for the United States. On being elected a senator of the United States, Hayne at once showed himself an active foe to protective legislation, and vigorously combated the tariffs of 1824 and 1828. A bill having been passed in 1832 removing the duty from these imports only which were not in competition with home manufactures, the state of South Carolina passed an ordinance nullifying the bill, on the ground that it was unconstitutional. President Jackson denounced this proceeding, and South Carolina, appointing Hayne governor, was preparing to defend its position by arms, when Congress made the desired change in the tariff, and South Carolina repealed its act. Hayne, on retiring from the governorship in 1834, was elected mayor of Charleston, and continued to take an active interest in public affairs till his death at Ashville, North Carolina, September 24, 1840. See *Life and Speeches of R. Y. Hayne*, 1845.

HAYTER, SIR GEORGE (1789-1871), principal painter in ordinary to the queen, was the son of a popular drawing-master and teacher of perspective who published a well-known introduction to perspective and other works. The son was born in London, and in his early youth went to sea. He afterwards studied in the Royal Academy, became a miniature-painter, and was appointed in 1815 miniature-painter to the Princess Charlotte. He passed some years in Italy, more especially in Rome, returned to London towards 1826, resumed portrait-painting, now chiefly in oil-colour, executed many likenesses of the royal family, and attained such a reputation for finish and refinement in his work that he received the appointment of principal painter, and teacher of drawing to the princesses. In 1842 he was knighted. He painted various works on a large scale of a public and semi-historical character, but essentially works of portraiture; such as *The Trial of Queen Caroline* (189 likenesses), *The Meeting of the First Reformed Parliament*, now in the National Portrait Gallery, *Queen Victoria taking the Coronation-oath* (accounted his finest production), *The Marriage of the Queen*, and *The Trial of Lord William Russell*. The artistic merits of Hayter's works are not, however, such as to preserve to him with posterity an amount of *prestige* corresponding to that which court patronage procured him. He is not to be confounded with a contemporary artist, John Hayter, who produced illustrations for the *Book of Beauty*, &c.

HAYTI.

HAYTI, variously known as Haiti, Santo Domingo, and named by Columbus, Espagnola or Little Spain (which last name was translated into the Latin, Hispaniola), is, with the exception of Cuba, the largest island of the West Indies, in the Antilles group.

It lies north between 17° 37' and 20° 0' lat., and west between 68° 20' and 74° 28' long.

The extreme length of the island is 407 miles from Cape Engaño on the east to Cape Tiburon on the west; the breadth of the

island is 160 miles from Cape Isabella on the north to Cape Beata on the south.

With the islands of Tortue or Tortuga on the northern coast, Gonaive on the west and Saone, St. Catherine, Beata, Alta Vela and other small islands along the south coast, it represents an area of 28,000 miles, which is about the size of Ireland. Cuba lies W. N. W. of Hayti, and Jamaica W. S. W., and between the islands flows the branch of the ocean known as the Windward Passage.

From Cuba the distance is 70 miles and from Jamaica 130 miles. Puerto Rico is sixty miles east, and between flows the Mona Passage. The appearance of Hayti on the map, from east to west, is suggestive of a turtle, owing to the strange formation of the extreme eastern peninsula which resembles the head, and the two western peninsulas which resemble the hind limbs of the creature.

The coast line is variously estimated at from 1,200 to 1,500 miles in extent, and in character is remarkable for the vast number of indentations and projections, which form many bays and natural harbors of refuge where vessels can seek shelter, and anchor safely in the roughest weather. Cape Tiburon is the extremity of the southwest peninsula, which is the largest in extent, being 150 miles long, and varying from 20 to 40 miles wide.

The northwest peninsula ranks second in extent, being 50 miles long and about 40 miles wide.

At the head of the bay formed by these two peninsulas, which together make an acute angle, stands the City of Port au Prince.

This bay is called the Gulf of Gonaive, from the Island of Gonaive, situated 27 miles from the city, 36 miles in length, and 8½ miles in breadth. The position of this island across the entrance to Port au Prince forms two channels, which are equally good for ships of all draughts, and gives a perfectly safe anchorage, 200 miles square, in all weather, between the city and the island; vessels of heavy draught are compelled to lie out 1½ miles from the shore, on account of the coral reefs.

The other principal port in the Gulf of Gonaive is St. Marc, which lies to the north of Port au Prince and has a considerable trade in coffee. Gonaives, a port of less consequence, is formed by a bay four miles across, with a small island in the middle. St. Nicolas Mole, the farthest point on the northwest peninsula, has an outer harbor, leading into an inner one, which is land-locked, and affords a splendid anchorage. The principal points on the north coast are Port de Paix, Acul Bay, Cape Hayti, named also Guarico, the Bay of Caracol or Port Royal, and Port Dauphin or Fort Liberté.

On the north coast there are no good harbors between Fort Liberté and Samana, Port Isabella forming no protection from the violence of the wind and sea, in bad weather, and Puerta Plata having a harbor full of shoals and surrounded with coral reefs.

At the extreme northeast of the island, the peninsula of Samana, which is simply a narrow mountain ridge, 35 miles in length, and varying from six to ten miles in breadth, extending into the sea, forms the bay of Samana.

The bay has an area of 300 square miles, and from east to west 30 miles in length, and from north to south 10 miles in breadth. The bay affords a good and safe anchorage for the largest ships in all weather, having a natural breakwater of coral reefs, stretching across the entrance from the south point to one and a half miles from the northern point, and from the north a number of small islets extend toward the reef for about three-quarters of a mile.

This leaves a somewhat narrow passage, but nevertheless deep and safe, for ships of all draughts to pass from the ocean into the bay.

After leaving the Bay of Samana, there are no ports on the east and south coast, until Santo Domingo is gained, which has a harbor containing two fathoms of water.

The Bay of Ocoa west of Santo Domingo, has an opening called Calderas Bay, which could be made into a magnificent harbor, if a passage were cut through the reefs which extend

across the entrance; further west is also the Bay of Neiba. Opening to the southeast is the almost circular bay of Jacmel. On this side are also the Bay of Baienet, the ports of Aquin and St. Louis and the open roadstead of Aux Cayes. Beyond Aux Cayes are the port of Jeremie and the Bay of Baradères which contains a fine harbor; these are the only ports until Port au Prince is reached.

The principal islands around the coast line are Gonaive, which has already been described, La Tortue or Tortuga, on the north, at one time a rendezvous and stronghold of the pirates, 22 miles in length, and five in breadth; off the south-east coast is La Saône or Adamanay, 15 miles by three and a half; lying off Aux Cayes is Ile de Vache, nine miles by two; in the Bay of Baradères, Great Cayemite, five miles by three, off Cape La Beata, La Beata, five miles by two. There are many small islands off the coast. In the Windward Passage is Navassa, which has been held by a private company from the United States, for the preparation of guano, since 1855.

Hayti is full of mountain ranges, but between the various ranges are many large plains or savannas, rich with luxuriant vegetation. The mountain ranges have three divisions, but all three divisions have generally an easterly and westerly trend; there is a northern, a midland and a southern chain. In the north, the Sierra de Monte Cristi runs from Cape Samana on the east to the Sella de Caballo on the west, close to Point Fragata. The highest mountain in this chain is Mount Diego Campo, in the center 4,000 feet above the level of the sea; the second is Sella de Caballo, 3,900 feet high. The midland chain commences on the east, by Point Macao, and stretches in a westerly direction to 70° 20' long, with an almost regular height of 1,000 feet; it then branches off into two separate chains, one of which runs in a northwest direction to Cape St. Nicolas, while the other bears away southwest to Mount Ocoa, and then turns westward to the coast, which it touches by St. Mare. In the western portion of the island, these two chains are united by an irregular and hooked-shape mountain ridge. The northern branch of this range forms the backbone of the island, and is called the Sierra del Cibao. Through the middle part of this chain, which is the Cibao proper, the average height is 7,000 feet, although in places it is between 8,000 and 9,000 feet. At the east end are the highest peaks, Loma Tina and Pico del Yaqui, being over 9,000 feet in height—and these are the two highest points on the island. The southern range of mountains, which forms the backbone of the southwest portion of the island, commences near the Bay of Neiba, and bears due west to Cape Tiburon. This chain has several names; at the eastern extremity it is called Baliruco, in the central portion La Sella, which name also belongs to the highest peak, nearly 9,000 feet high; in the west end it is called La Hotte. La Vega Real (the Royal Plain) is the most extensive and richest of the large plains or savannas, and lies between the middle of the Cibao and Monte Cristi ranges. It is about 140 miles in length, and fourteen miles in breadth, and extends from Samana Bay to Manganillo Bay. This valley was named La Vega Real by Columbus, but that name is limited now to the eastern half; the western portion is called the valley of the Santiago, and the whole plain is named the Valley of Cibao. It is irrigated by the north or Gran Yaqui river, the Yuma river and their tributaries. From the river Ozama, the plain of Seybo extends for 95 miles in an easterly direction, with a breadth of about 16 miles, and is plentifully irrigated by the rivers Ozama, Soco, Macoris, Quiabon and Yuna. The greater part of the valleys and plains are altogether uncultivated, being partly pasture land or savanna, and partly forest, and they are eminently suitable for raising all kinds of stock. The Gran Yaqui river has its source in the Pico de Yaqui, and follows a winding course in a northwesterly direction through the Valley of St. Gague, and falls into the Bay of Manganillo. It is navigable only by canoes and small boats. The Neiba or Neiva, sometimes called the South Yaqui has its source in the Pico del Yaqui and the Entre del Rios, and following a southerly course empties itself into the Bay of Neiba, in the Caribbean sea. The Yuna, remarkable for the swiftness of its current,

arises on Loma Tina, and flows through the fertile Valley of Vega Real into the Bay of Samana. Small vessels drawing only a few feet of water can proceed up the river to its confluence with Camu, and canoes and small boats can ascend with cargoes as far as Concepcion de la Vega. The Ozama has a very deep bed, and affords a passage for a few miles up from its mouth, for vessels of light draught; it runs south and empties itself into the Caribbean Sea. The Artibonite flows into the Bay of Gonaive to the north of St. Mare; it is a shallow stream whose waters are teeming with caymans. There are several other streams of insignificant size, which flow into the great salt salve of Enriquillo or Xaragua, which also bears the French name of Etang Salé (Salt Lake), and is situated on the south shore. This is the largest lake on the island, being 27 miles in length by eight in breadth; the specific gravity of its waters is the same as that of the ocean, from which it is 25 miles distant; it has regular tides, which indicate some subterranean connection with the Caribbean Sea. Many varieties of fish and caymans abound in it. Next in size to this is Lago de Fondo, or, in the French, Etang Saumâtre (Brackish Lake), which is 16 miles in length by four in breadth. Icotea de Limon is a fresh-water lake, with no outlet apparently, five miles in length and two in breadth. Rincón and Maragoane are two smaller lakes of no importance. For the most part the waters of the rivers are too turbid and full of earth to be used for drinking purposes. But some of the mountain streams and the small fresh-water lakes afford clear and wholesome water for drinking.

The greater part of the coast line of Hayti is of considerable elevation.

Earthquakes are of common occurrence, but there are no volcanoes in activity at the present time.

No rocks older than those of the second period have yet been found; the center and heart of the island is formed of limestone, conglomerate and slate, interspersed with syenitic masses.

A large amount of tertiary deposits, bordered by newly-formed limestone and gravel, are found to the front of the slate and rocks of the Sierra, in the north; and in portions of the south of the island.

The Sierra, of which the central range of mountains consists, which penetrates the whole of the Santo Domingo Republic, and forms the peninsula of Samana, and the smaller one of Porto Plata, is formed of upturned and forcibly compressed rock of changed appearance, which consisted originally of clay shale, sandstone, sandstone conglomerate, and limestone.

In the western portions of the island, these masses are broken and divided by deep dykes and rocky valleys.

There is gold quartz found in the slates, near volcanic masses, and also in the beds of the streams which flow through the metamorphic rocks, if in the vicinity of syenite or granite formations.

The rivers Nigua, Jaina, Nizao and Ocoa, also many of the streams which feed the Yaqui, and descend from the northern side of the Sierra del Cibao, have more or less gold in their sands, but not in any large quantities.

The lignite-bearing strata found in the Upper Miocene beds are useless for domestic and commercial purposes, being only a few inches thick, and full of various foreign matters. The minerals of the island consist of gold, platinum, silver, mercury, copper, iron, tin, manganese, antimony, rock-crystal, jasper, porphyry, sulphur, marble, opal, chalcodony, lazulite, rock-salt, and bitumen. Many kinds of mineral springs abound, impregnated with iron and sulphur, and other like properties. The fossil formations of the Miocene strata very closely resemble those of the Pacific coast in character, and tend to confirm the deduction that during the early period of the Miocene period, the Pacific and Atlantic oceans held uninterrupted connection. For particulars of the geology of Hayti consult Professor Gable, *Trans. Amer. Phil. Soc.* xv., 49, and on the Miocene fossil formation, Guppy, *Quart. Geol. Soc., Lond.*, xxxii., 1876, p. 516. There are not a great variety of animals in Hayti. The largest wild animal is the agonti, a gregarious creature, about the size of, and much resembling, the hare; the flesh is tender and very

good to eat. Wild cattle, horses, hogs, and dogs roam in large herds throughout the forests, and over the savannas; they are descended from the animals originally imported from Europe, and afford sport for the natives, who hunt them frequently, and especially the wild hogs, which are pursued with dogs. There are very few varieties of birds, with the exception of water fowl and pigeons, which are found in large numbers. Snakes are numerous, but very few are poisonous, the majority being quite harmless. In the low-lying country, insects swarm in myriads, including scorpions, centipedes, and the deadly tarantula. Caymans abound in the lakes and rivers, which also are full of fish of many varieties. The sea, around the coast, also abounds in oysters, lobsters, crabs, and all kinds of salt-water fish. The soil of Hayti will produce every variety of known vegetable, in rich prodigality, and in this respect is unsurpassed by any country in the world.

In the lower lands all tropical productions grow to perfection, and amongst the mountains are produced the vegetables and fruits of temperate latitudes. A vast quantity of productions are indigenous to the soil, including rice, cotton, tobacco, maize, cocoa, ginger, arrowroot, manioc, generally called cassava, pimento, banana, plantain, pineapple, artichoke, yam, sweet potato, and native indigo (indigo marron or sauvage). From originally imported plants, there grow, excellent sugar-cane, coffee, indigo (called *indigo franc* in distinction to the indigo sauvage), melons, peas, beans and all leguminous vegetables, cabbages, lucerne, guinea-grass, bamboo, breadfruit, mango, caimite, orange, almond, apple, mulberry and fig. The vanilla and grapevine trail their sinuous lengths through the vast forests, and from the grapes is produced a very good muscatel wine. Many of the finest fruits have deteriorated from want of proper attention, and a destructive insect wages remorseless war upon the roots of the bamboo. The mango, which is very wholesome, has now become a recognized staple of daily food, and in that respect has taken precedence of the breadfruit, which also is commonly used as an article of diet. Hayti is rich in valuable timber, for furniture, building purposes, and also for the manufacture of dyes. The timber for furniture and building includes mahogany, manchineel, satinwood, rosewood, cedar, walnut, ebony, and wax-palm, cinnamon wood, yellow acoma, and gri-gri; among the dye-woods are fustie, logwood, Brazil wood, sassafras, the campeachy, from which is produced a red dye, the yaws tree, a yellow dye, and several others, in addition to the indigo-plant, and the cochineal fig. Pine forests and oak cover many parts of the mountains; and there are also found the palmetto, several varieties of palm, the cypress or Bermuda cedar, the locust and ironwood.

In Hayti, as in all tropical and sub-tropical countries, there are two seasons, a wet season from May to October, and a dry season from November to April, inclusive. The rains fall most abundantly in May and June, when the rivers, which are almost dry for the greater part of the year, fill up rapidly, and often overflow their banks, and flood the surrounding country. In the months of June, July and August, the heat usually increases to 100° and over in the plains, and to 77° in the mountains; in the highlands a fire is often quite acceptable, and especially in the evening.

In Hayti can be found almost every variety of climate, from several causes—the shape of the island, the fact of so much of it being mountainous and so much on a low level, the position of the island in the very track of the trade winds, and the quantity of timber, water, etc., throughout. During the months of June, July and August, violent storms and hurricanes break over the island, although they are not so frequent as in the Windward Islands. The east wind predominates.

Hayti has suffered much from earthquakes, which have occasionally destroyed whole cities. Farming has advanced but little in the island, and the appliances used are of the most crude description. The articles of produce which were cultivated in the days of slavery, and which made the island famous for its exports, are not now cultivated to any extent.

Coal exists in the vicinity of St. Yagul, along the banks of the river Anbaji, in many portions of the North Artibonite and in the south, in the Haytian Republic. Copper and iron mines exist in the island of Gonave and on the peninsula of Samana. These mines have been thoroughly explored, and in the past have been worked with some profit, but for long, mining has been abandoned for want of capital. Cabinet and dye-woods are cut in the interior for exportation, and hides, wax and honey are also prepared for the same purpose. The commerce of the country is carried on principally by Americans and Europeans who have settled in the towns and cities. There is a population of between 1,100,000 and 1,200,000, of which about 572,000 are citizens of the Western Repub-

lic of Hayti, and about 610,000 are citizens of the Republic of Santo Domingo in the east. There are over 500,000 pure Africans in the Republic of Hayti, and a very large number in the eastern republic. There are about 125,000 of Spanish and 50,000 of French origin. There are Americans from the United States, English, Germans and Italians, carrying on business in the seaport towns. Spanish is spoken in the Dominican Republic and a sort of mongrel French in the Western Republic.

Hayti was discovered by Columbus, who landed on St. Nicolas Mole, December 6, 1492, the day after leaving Cuba. There were then about 2,000,000 inhabitants, who are represented by the Spaniards as being of a low type of humanity, and were treated by them with the usual cruelty with which they invariably visited the unfortunate aborigines in those countries which they conquered. Fabulous stories of the presence of gold brought many adventurers from the old country, who oppressed the natives and compelled them to work for them as slaves in their search for the hidden treasure.

Their cruelty and severity finally roused the natives to resistance and some of them fought bravely, but without success, for their liberty. At the end of 30 years, from the treatment of their cruel masters, and being unused to the hardships of the mines, the aboriginal race had almost disappeared. In 1517 a royal edict was issued, authorizing the importation of 4,000 negroes from Africa, each year, to be used for working the mines and plantations as slaves, the experiment having been tried, ten years previously, of bringing over a few, which had proved entirely successful, as they were a stronger race and better able to stand the toil and labor. The first negro slaves were kept on the plantation of Pedro, the son of Christopher Columbus, the governor of the island. In 1711 only 21,000 of the natives remained in the island, and in the present day it is supposed that the race is entirely extinct, with the exception of a few who are reported to be living in the Bahoreo mountains. The Spaniards also decreased in numbers and left for the more recently discovered countries of Mexico and Peru. This magnificent land was then almost deserted. But in 1630, a number of French and English adventurers, who called themselves buccanniers, and were really pirates, settled on the island of Tortuga, which they made into a stronghold from which they sailed on depredatory expeditions. These crossed over to Hayti, and formed a settlement on the northern shore, which was recognized as an independent department in 1714, that part of the island having been ceded to France in 1697 by the treaty of Ryswick. In 1777 a definite boundary line was laid down, extending from the mouth of the Daxabon or Massacre in the north, to the outlet of the Pedernales or Anses à Pitres in the south. The colony prospered exceptionally until the outbreak of the French revolution, 1789. At this time there existed a three-cornered problem in the island, which was destined to solve itself only after terrible bloodshed and pitiless war. The population consisted of three classes, whites, free colored people and slaves. The free colored people were largely men of wealth and means, owning fine estates in the colony, and were also intelligent, educated and refined, but they had no political rights. In 1790, influenced by the revolutionary ideas which were then convulsing France, the mulattoes demanded political recognition, and when this was refused by the whites they took up arms to enforce their claim. They were defeated and their leaders were captured and executed. In 1791, the national convention granted to the mulattoes all the privileges of French citizens, in spite of the remonstrance of the whites. On August 23, 1791, the insurrection of the negro slaves occurred, and then the whites endeavored to conciliate the mulattoes, for the sake of their assistance in the coming struggle. But just at this time the home Government reversed the decree of the national convention, granting to the mulattoes political rights as French citizens, and this settled their decision.

From that moment they united and made common cause with the negroes in the bloody war which followed. For several years the war raged with no apparent advantage to either side, and each party was disgraced by acts of unnecessary cruelty and vengeance. Commissioners with full power came from France to settle the difficulty, but accomplished nothing. In 1793, the abolition of slavery was formally proclaimed, and the problem was settled by the granting of equal rights to all. In September, 1793, the British sent a force to capture the island, but they effected little on account of the ravages which the climate made on the troops. At this time Toussaint L'Ouverture, the leader of the blacks, came to the assistance of the French Government, and was appointed commander-in-chief of the French army in the colony; by his vigorous measures and capable leadership the English were compelled to retire from the island in 1798. In 1795, Spain ceded the whole island to France, in the treaty of Basle, and it then received the name of Saint Domingue. In 1801, a constitutional form of government was adopted by the country, and Toussaint was elected president for life. At this time Bonaparte, first consul of France, determined to reduce the island to dependence and consign the blacks to slavery. General Leclerc was sent with 25,000 troops to accomplish this purpose, but failed altogether. He therefore invited Toussaint to an interview, and then treacherously seized him and sent him to France, where he died in prison in 1803. His successor Dessalines was a man of considerable power and ability, and he prosecuted the war with such success against the French, that combined with the yellow fever, and the arrival of a British fleet off the coast, the French lost heart, and on November 30, 1803, 8,000 French troops surrendered to the British admiral. In 1804, St. Domingue proclaimed itself an independent republic, under the aboriginal name of Hayti. Dessalines was elected governor for life, but on October 8, 1804, he broke the constitution, declared himself emperor, and was crowned with great pomp and ceremony. After this unwise step, he became cruel and tyrannical, as well as vainly emulative of the customs of royalty in older countries. Outbreaks and civil wars resulted from his conduct, until he was assassinated in 1806. Several chiefs now strove for the leadership, and while Christophe was fighting for the supremacy in the north, and Pétion in the south, the eastern portion of the island permitted the Spaniards to regain a footing, and form a Spanish province under a title of Santo Domingo, a modified form of the French name. The war between Christophe and Pétion lasted until 1810, when hostilities ceased, and Christophe proclaimed himself king, with the title of Henry I. In 1820 he committed suicide, after

causing an insurrection by his cruelty and tyranny. Pétion died in 1818, and so in 1822, General Boyer took supreme control of the whole of the French part of the island, and was elected president. In 1821, the Spanish colony of Santo Domingo proclaimed its independence of the old country, but by its internal dissensions invited an attack from its French neighbor, and in 1822 was conquered by General Boyer, who remained as President of the whole island until he was compelled to fly from the country by a revolution in 1843. In 1844 the people in the east again proclaimed their independence, and established the Dominican Republic, which has maintained its freedom and independence until the present day. The Spaniards made one last effort to regain their claim on Santo Domingo, in 1861, but failed in the attempt and retired finally in 1863.

In Hayti several presidents followed each other in rapid succession, but were speedily deposed or resigned. In 1846, Soulouque was elected president; he was a full-blooded negro, who in early life had been a slave. He made an unsuccessful attempt to reconquer the eastern Republic, but obtained no advantage. In 1849 he assumed the imperial title, and the following year was crowned as Faustin I. emperor. But the people tired of imperial government, and in 1853 he was deposed, and a republican government was organized, with Fabre Geffrard as president. He became unpopular, and in 1867 an insurrection compelled him to resign hastily and escape to Jamaica. The next president was Sylvestre Salnave. The people rose against him in 1868, and although he made a stout resistance for two years, he was finally captured and shot by the insurgents in 1870. Nissage-Saget was elected to the presidency on May 29, 1870, and General Michel Domingue on June 10, 1874; he abdicated in 1875, and was succeeded by General Boisron-Canal, who resigned and left the country July 17, 1879. General Salomon was elected for seven years on October 23, 1879. On May 1, 1887, General Salomon was re-elected to the presidency. General Légitime was elected president on August 14, 1888, but his authority was recognized only in the north, and General Hippolyte, the leader of the opposition, was elected provisional president. Civil war ensued, which lasted from the fall of 1888 to September, 1889, and ended in the defeat of Légitime and the unanimous election of General Hippolyte to the presidency on October 17, 1889.

Haytian Republic.—The Republic of Hayti is situated in the western portion of the island, and is separated from the Republic of Santo Domingo by a boundary line extending from the river Massacre on the north to the river Pedernales on the south. It possesses an area of about 10,000 square miles. It is governed with a constitution adopted October, 1889, under President Hippolyte. The government consists of three departments, the legislative, executive and judicial. The legislature has a chamber of commons and a senate. The members of the former are elected for three years, the latter for six years. The executive power is vested in a president elected for four years by both houses of legislature in joint convention. The president appoints his cabinet, composed of 11 "Ministers of State." The revenue and expenditure for 1885-86 is given as \$6,412,997. The Budget estimates for 1887-88 gave expenditure as 4,066,236 piastres. The foreign debt incurred in Paris in 1825, with other liabilities incurred to France, amount to 32,049,810 francs, or £1,281,991, and no interest has been paid for many years. The total external and internal debt amounted to \$13,500,000 in 1887. Since October, 1881, the National Bank of Hayti has gone into business with a capital of £800,000 in 2,000 shares. The nominal strength of the army is 6,828 men, but in time of war all able-bodied men are liable for service. The chief trade of Hayti is carried on with the United States and Great Britain. Coffee, mahogany and logwood are the principal exports; the principal imports are linen and cotton goods. Prior to the civil war of 1853-59, the imports into Hayti were \$6,000,000 per annum, and the exports \$9,000,000, the bulk of the business being with the United States. In 1887, British cottons to the value of £509,521 were imported, and linens to the value of £34,869. The weights and measures in use are French; and so also is the gold and silver coinage. The national bank of Hayti can issue bills, which are generally accepted. The piastre or dollar of the Republic is now worth three shillings and four pence. The capital, Port au Prince, in 1887 had a population estimated at about 60,000. The national religion of Hayti is the Roman Catholic religion.

Dominican Republic.—The Republic of Santo Domingo, which is generally called San Domingo and officially is the República Dominicana, has an area of 18,000 square miles and an estimated population in 1888 of 610,000. It consists of five states—Santo Domingo, Santa Cruz del Seibo, Concepcion de la Vega, Santiago de los Caballeros, and Agua de Compostela, each having its own legislature and governor; also two maritime districts of Porto Plata and Samana. It is governed by a constitution adopted in 1844, but changed, modified and improved in 1865 and again in 1888. The chief executive is a president elected for four years; Gen. Ulysses Henreux was elected in 1886 to the presidency. The president appoints his own ministry, and the legislature is composed of a senate of nine members. The income in 1887 is given as \$1,184,434, the expenditure as \$787,164. On January 1, 1889, the home debt amounted to \$2,931,376, the foreign debt to England \$1,520,500, bearing 6 per cent. interest. There is a small army of cavalry, infantry and artillery, a regiment of which is stationed in each province or state, and compulsory military service is enforced in time of war. The principal imports consist of cottons, linens, woollens, hardware, rice, and railway materials. The chief articles exported in 1888 were: Tobacco, sugar, coffee, honey, wax, cabinet and dye woods. The imports in 1887 amounted to \$2,056,928, and in 1888, \$1,992,885. The exports in 1887 amounted to \$2,660,471, and in 1888 to \$2,529,988. The difference in the two years is to be traced to the political disturbances and civil war in the sister republic of Hayti. In 1885, 26,000 tons of sugar were exported. In 1887, 175,637 cwt. of tobacco were exported, 2,731 cwt. of cocoa, 406,142 cwt. of sugar, and 476,933 cwt. of molasses. Turtle shell is also largely exported. Santo Domingo, the capital of the republic, was founded in 1492; it is situated at the outlet of the Ozama river, and has a population of 25,000 people. The Roman Catholic religion is the national religion of the country.

See *Statesman's Annual*, published annually in London. Hazard gives a full list of works relative to the island. The best map of Hayti is published by Rand, McNally & Co., of Chicago and New York. (W. W.)

HAYWARD, SIR JOHN (c. 1560-1627), one of the earliest writers of English history as distinguished from the old chroniclers, was born about 1560 at or near Felixstow on the coast of Suffolk. According to a statement in his will he "received the means of his education" out of the parish of Felixstow. It is affirmed by the old authorities that he studied at Cambridge and took the degree of doctor in civil law, but his name does not occur in any of the registers. In 1599 he published *The First Part of the Life and Raigne of King Henrie the IIIII.*, extending to the end of the first year of his raigne, which, from its dedication to the earl of Essex, and a passage it contained on hereditary rights, led to the author's imprisonment by Elizabeth. The queen also caused Francis Bacon to search the book for "places in it that might be drawn within case of treason," who reported, "For treason surely I find none, but for felony very many,"—explaining that many of his sentences had been stolen from Cornelius Tacitus. Notwithstanding this jocular exculpation Hayward was continued in prison, in all probability until after the death of the queen. On the accession of James I. he courted that monarch's favour by the publication of two political pamphlets—*On the Right of Succession* (1603), and *A Treatise of Union of England and Scotland* (1604); and in 1610 he was appointed historiographer along with Camden of the college which King James attempted to found at Chelsea. In 1613 he published his *Lives of the Three Norman Kings of England*, which he wrote at the request of Prince Henry. In 1616 he was admitted an advocate of Doctors Commons, and in 1619 he received the honour of knighthood. He died 27th June 1627. Among his manuscripts was found *The Life and Raigne of K. Edward VI.*, first published in 1630, and *Certain Yeres of Queen Elizabeth's Raigne*, the beginning of which was printed in an edition of the *Reign of Edward VI.*, published in 1636, but which was first published in a complete form in 1840, for the Camden Society, under the editorship of John Bruce, who prefixed an introduction on the life and writings of the author. Hayward was conscientious and diligent in obtaining information, and, although his reasoning on questions of morality is often childish, his descriptions are generally graphic and vigorous. Notwithstanding his imprisonment by Elizabeth, his portrait of the qualities of her mind and person is flattering rather than detractive.

HAZARA, or HUZARA, a British district in the lieutenant-governorship of the Punjab, India, lying between 33° 45' and 35° 2' N. lat., and between 72° 35' 30" and 74° 9' E. long. It forms the north-eastern district of the Peshawar Division, and is bounded on the N. by the Black Mountains, the Swathi country, Kohistan, and Chilás; on the E. by the native state of Kashmir; on the S. by Rawal Pindi district; and on the W. by the river Indus. The area is 2771 square miles.

The district forms a wedge of territory extending far into the heart of the outer Himalayan range, and consisting of a long narrow valley, shut in on both sides by lofty mountains, whose peaks rise to a height of 17,000 feet above sea level. Towards the centre of the district the vale of Khágán is bounded by mountain chains, which sweep southward still maintaining a general parallel direction, and send off spurs on every side which divide the country into numerous minor dales. The district is well watered by the tributaries of the Indus, the Kunhar, which flows through the Khágán Valley into the Jhelum, and many rivulets. Throughout the scenery is picturesque. To the north rise the distant peaks of the snow-clad ranges; midway, the central mountains stand clothed to their rounded summits with pines and other forest trees, while grass and brushwood spread a green cloak over the nearer hills, and cultivation covers every available slope.

The enumeration of 1868, which extended over an area of 3000 square miles (including the feudal territory of Tanawal), showed a population of 367,218 (males, 191,423; females, 176,795). The Mahometans numbered 346,112; Hindus, 18,563; Sikhs, 973; "others," 1670. The gross revenue in 1875-76 was £25,292. In the same year the police force numbered 510 men, besides 390 village watchmen; and there were 24 schools with 1042 pupils. The principal crops consist of wheat, barley, oil-seeds, maize, rice, pulses, millets, and cotton. Out of a cultivated area of 393,918 acres, 36,380 are artificially irrigated by means of wells and embankments on the rivers and hill torrents. Hazára has not suffered from any calamity since the famine of 1783, which affected it as well as the rest of Upper India. The chief imports are English cloth, salt, indigo; and the exports *ght*, mustard oil, barley, wheat, rice, and live stock. In 1875-76 there were 676 miles of unmetalled roads within the district. The average rainfall for the eight years ending 1873-74 amounted to 47 inches. The station of Abbottábád is the headquarters of the Panjab frontier force.

History.—The name Hazára probably belonged originally to a Túrki family which entered India with Timúr in the 14th century, and subsequently settled in this remote region. During the prosperous period of the Mughal dynasty, the population included a number of mixed tribes, which each began to assert its independence, so that the utmost anarchy prevailed until the time when Hazára attracted the attention of the rising Sikh monarchy. Ranjit Sinh first obtained a footing in the district in 1818, and, after eight years of constant aggression, became master of the whole country. During the minority of the young Mahárája Dhulip Sinh, the Sikh capital fell into a state of complete disorganization; the people seized the opportunity for recovering their independence, and rose in 1845 in rebellion. They stormed the Sikh forts, laid siege to Haripur, and drove the governor across the borders. In the following year the greater part of the district was included in the territory ceded to Rájá Ghuláb Sinh by the British, at the conclusion of the first Sikh war. On the outbreak of the second Sikh war the troops in garrison revolted, but the Mussulman inhabitants supported Lieutenant Abbott under the Lahore Government, and the insurrection was soon quelled. Since then Hazára has passed under direct British rule, and has enjoyed for more than quarter of a century uninterrupted peace.

HAZARAS. See AFGHANISTAN.

HAZARD, a game played with dice. The player or "caster" calls a "main" (that is, any number from five to nine inclusive). He then throws with two dice. If he "throws in," or "nicks," he wins the sum played for from the banker or "setter." Five is a nick to five, six and twelve are nicks to six, seven and eleven to seven, eight and twelve to eight, and nine to nine. If the caster "throws out" by throwing aces, or deuce, ace (called crabs), he loses. When the main is five or nine the caster throws out with eleven or twelve; when the main is six or eight he throws out with eleven; when the main is seven he throws out with twelve. If the caster neither nicks nor throws out, the number thrown is his "chance," and he keeps on throwing till either the chance comes up, when he wins, or till the main comes up, when he loses. When a chance is thrown, the "odds" for or against the chance are laid by the setter to the amount of the original stake.

Suppose, for example, 7 is the main. If the caster throws 7 or 11 he wins; if he throws aces, crabs, or 12 he loses. If he throws any other number, that is his chance. Say 7 is the main and 4 the chance, the odds against the caster are now 2 to 1 (as will appear from the table below). If the stake were £1, the setter would lay £2 to £1 in addition. The caster goes on throwing till either 7 or 4 appears, when he loses £2 or wins £3.

In laying the odds, the setter gains no advantage, as can easily be shown, examining the various ways in which two dice can be thrown.

	Ways	
2	1 and 1,	1
3	2 — 1, 1 and 2,	2
4	2 — 2, 3 — 1, 1 and 3,	3
5	4 — 1, 1 — 4, 3 — 2, 2 and 3,	4
6	3 — 3, 5 — 1, 1 — 5, 4 — 2, 2 and 4,	5
7	6 — 1, 1 — 6, 5 — 2, 2 — 5, 4 — 3, 3 and 4,	6
8	4 — 4, 6 — 2, 2 — 6, 5 — 3, 3 — 5,	5
9	6 — 3, 3 — 6, 5 — 4, 4 — 5,	4
10	5 — 5, 6 — 4, 4 — 6,	3
11	6 — 5, 5 — 6,	2
12	6 — 6,	1

In all 36 ways. The table shows that there are six ways in which 7 can be thrown, three ways in which 4 can be thrown. Hence the odds are 6 to 3, or 2 to 1.

But there is always an advantage in favour of the setter on the stake first played for. The least disadvantageous main for the caster to call is 7.

Take the case in which 7 is the main and £18 (to avoid fractions) the caster's stake, and £36 therefore the sum played for. Then (1) if 7 or 11 is thrown the caster wins. There are eight ways out of 36 in his favour; therefore his expectation on nicking is $\frac{8}{36}$ ths of £18 = £8. (2) If the chance is 6, in order to win he must throw 6 before he throws 7. There are five ways of throwing 6, and six ways of throwing 7. His expectation on 6 is therefore $\frac{5}{12}$ ths of £36 = £2, 5s. 5½d. (3) The expectation on a chance of 8 is the same as on 6, viz., £2, 5s. 5½d. (4 and 5) If the chance is 9 or 5 the expectation is $\frac{3}{12}$ ths of ½d of £36 = £1, 12s. (twice). (6 and 7) If the chance is 10 or 4 the expectation is $\frac{3}{12}$ ths of ½d of £36 = £1 (twice). The total expectation of the caster is all the separate expectations added together, viz., £17, 14s. 11d. If his expectation were equal to the setter's, it should amount to £18. Therefore the caster's expectation is 5s. 1d. less than it would be if the probabilities of his winning or losing were equal. This makes his disadvantage when 7 is the main equal to 3½d. and half a farthing in the pound.

The calculations applied to the main of 7 can easily be made use of for any other main, when it will be found that the caster's expectation of loss when 5 or 9 is the main is 3½d. and half a farthing in the pound, and when 6 or 8 is the main 5½d. and nearly half a farthing in the pound.

HAZÁRIBÁGH, a British district in the lieutenant-governorship of Bengal, India, lying between 23° 25' and 24° 48' N. lat., and between 84° 29' and 86° 38' E. long. It is bounded on the N. by the districts of Gayá and Monghyr, on the E. by the Santál Parganá and Mánbhúm districts, on the S. by Lohárdagá, and on the W. by Lohárdagá and Gayá; it forms the north-east portion of the Chutíá Nágpur division, and has an area of 7020 square miles.

The physical formation of Hazáribágh exhibits three distinct features—(1) a high central plateau occupying the western section, the surface of which is undulating and cultivated; (2) a lower and more extensive plateau stretching along the north and eastern portions; to the north, the land is well cultivated, while to the east the country is of a more varied character, the elevation is lower, and the character of a plateau is gradually lost; (3) the central valley of the Dámodar river occupying the entire southern section. Indeed, although the characteristics of the district are rock, hill, and wide-spreading jungle, fine patches of cultivation are met with in all parts, and the scenery is generally pleasing and often picturesque. The district forms a part of the chain of high land which extends across the continent of India, south of the Nerbudda on the west, and south of the Són river on the east. The most important river of Hazáribágh is the Dámodar, with its many tributaries, which drains an area of 2450 square miles. The only other river of any importance is the Barakhar. The jungle gives shelter to wild animals of all sorts. Game birds are plentiful.

The census of 1872 showed a population of 771,875 (males, 397,045; females, 374,830). Belonging to aboriginal tribes there are 57,120; semi-Hinduized aborigines, 216,712; Hindus, 421,622; persons of Hindu origin not recognizing caste, 2664; Mahometans, 72,338; non-Asiatics, 1362; and mixed races, 67. Three municipalities contain more than 5000 inhabitants:—Hazáribágh, 11,050; Jehak, 8999; and Chhatrá, 8818. The only place of special interest is Parasnáth Hill, a celebrated place of pilgrimage, which is annually visited by large numbers of Jain worshippers. The revenue in 1870 amounted to £32,841, and the expenditure to £31,367. The regular police force (1872) numbered 557 men of all ranks; municipal force, 65; and rural police, 3834 men; maintained at a total cost of £15,763. There were, in 1873, 66 schools with 2183 pupils. Rice is the staple crop, and the three principal kinds are grown. Among the other crops are wheat, barley, Indian corn, the usual pulses and green crops of Bengal, jute, flax, aloes, sugarcane, opium, cotton, &c. The trade is concentrated at Chhatrá, the great central market. The chief exports are lac, metal cooking utensils, *ght*, iron, and cattle; and the imports, rice, salt, cattle, and tobacco. There are 400 miles of road. Six coal-fields are known to exist in the district,—the most important being that of Karharári, which is capable of supplying 250,000 tons a year for 3000 years. In 1877 there were three tea plantations containing mature plants, and one on Parasnáth Hill which promises well. The average mean temperature for 1874 was 74° F.; the average

yearly rainfall, 52.4 inches. The climate is very healthy, but rheumatism, fever, and dysentery are not uncommon; cholera is rare.

The history of the district is involved in obscurity until 1755, about which time a certain Mukund Sinh was chief of the country. In a few years he was superseded by a Tej Sinh, who had gained the assistance of the British. In 1780 Hazáribágh, along with the surrounding territory, passed under direct British rule.

Hazáribágh, the chief town and administrative headquarters of the above district, is picturesquely situated on the high central plateau of the district, at an elevation of 2000 feet above sea-level, and in the midst of a group of conical hills, 23° 59' 21" N. lat. and 85° 24' 32" E. long. The town is little more than a cluster of villages, with intervening cultivation, which have sprung up round the military *bázár*. Hazáribágh has been the military headquarters of the district since 1780, and the seat of civil administration since 1834. The cantonment lies south-east of the town. Population in 1872, 11,050 (6312 males, 4738 females):—Hindus, 7240; Mahometans, 3384; Christians, 52; "others," 374.

HAZEBROUCK, a town of France, capital of an arrondissement of the same name in the department of Nord, is situated on the Bourre, 32 miles W.N.W. of Lille, in a district formerly covered with marshes. It stands on the Lille and Calais Railway, at the junction of the branch from Dunkirk. The town is governed by a sub-prefect, and has a court of primary instance with two juges de paix, besides various offices of excise and inland revenue. There are numerous religious and charitable societies including the Frères des Écoles Chrétiens, Sœurs de Charité, and Dames de la Sainte Union. The convent of Capuchins, built near the town in 1854, is now occupied by a school. Hazebrouck contains some handsome public buildings, as the church of St Nicolas, with a tower 260 feet high, of fine open work, built about 1520, the hôtel de ville (1807–1813), the prison for the department, two theatres, and the communal college. The Augustinian convent, built in the 16th century, with a façade of the 17th century, is now occupied in its several parts by the hospital, a tobacco-warehouse, a market, and college lecture-rooms. A chamber of agriculture meets in the town, where there are also a small public library and a secondary school. The principal manufactures are linen cloth, thread, soap, beer, oil, lime, and salt. There are also tanneries, salt-refineries, corn-mills, and dye-works. Trade in country produce, cattle, timber, and hops is also carried on. Population (1876) of the district 9857, of the town 6363.

HAZEL (Anglo-Saxon, *Hæsel*;¹ German, *Hasel*; French, *Noisetier*, *Coudrier*), *Corylus*, Tournef., a genus of shrubs or low trees of the natural order *Cupuliferæ* and sub-order *Coryleæ*. The common hazel, *Corylus Avellana*, L., is distributed throughout Europe, in North Africa, and in Central and Russian Asia, except the northernmost parts. It is commonly found in hedges and coppices, and as an undergrowth in woods, and reaches a height of some 12 feet; occasionally, as at Eastwell Park, Kent, it may attain to 30 feet. According to Evelyn (*Sylva*, p. 35, 1664), hazels "above all affect cold, barren, dry, and sandy soils; also mountains, and even rockie ground produce them; but more plentifully if somewhat moist, dankish, and mossie." In Kent they flourish best in a calcareous soil. The bark of the older stems is of a bright brown, mottled with grey, that of the young twigs is ash-coloured, and glandular and hairy. The leaves are alternate, from 2 to 4 inches in length, downy below, roundish-cordate, pointed, and shortly petiolate; occasionally they are found with the margins coherent at the base, or with the disk so depressed as to

form a pitcher-like structure (Masters). In the variety *C. purpurea*, the leaves, as also the pellicle of the kernel and the husk of the nut, are purple, and in *C. heterophylla* they are thickly clothed with hairs. In autumn the rich yellow tint acquired by the leaves of the hazel adds greatly to the beauty of landscapes. The flowers are monœcious, and appear in Great Britain in February and March, before the leaves, and sometimes in October (London). The cylindrical, drooping, and yellow male catkins (see BOTANY, vol. iv. p. 123, fig. 161) are 1 to 2½ inches in length, and occur 2 to 4 in a raceme; when in unusual numbers they may be terminal in position. The female flowers are small, subglobose, and sessile, resembling leaf-buds, and have protruding crimson stigmas; the minute inner bracts, by their enlargement, form the palmately lobed and cut involucre or husk of the nut. The ovary is not visible till nearly midsummer, and is not fully developed before autumn. The nuts have a length of from ½ to ¾ inch, and grow in clusters. Double or treble nuts are the result of the equal development of two or all the three carpels of the original flower, of which ordinarily two become abortive. Fusion of two or more nuts is not uncommon, and Masters gives an instance of the union of as many as five. From the light-brown or brown colour of the nuts the terms *hæzi* and *hæzelli*, i.e., "in hue as hazel nuts" (Shakespeare, *Taming of the Shrew*, ii. 1), derive their significance.² The wood of the hazel is whitish-red, close in texture, and pliant, and has when dry a weight of 49 lb per cub. foot; it has been used in cabinet-making, and for toys and turned articles. Curiously veined veneers are obtained from the roots; and the root-shoots are largely employed in the making of crates, coal-corves or baskets, hurdles, withs and bands, whip-handles, and other objects. The rods are reputed to be most durable when from the driest ground, and to be especially good where the bottom is chalky. The light charcoal afforded by the hazel serves well for crayons, and is valued by gunpowder manufacturers. An objection to the construction of hedges of hazel is the injury not infrequently done to them by the nut-gatherer, who "with active vigour crushes down the tree" (Thomson's *Seasons*. "Autumn"), and otherwise damages it.

The filbert,³ among the numerous varieties of *Corylus Avellana*, is extensively cultivated, especially in Kent, for the sake of its nuts, which are readily distinguished from cob-nuts by their ample involucre and greater length. It may be propagated by suckers and layers, by grafting, and (see ARBOICULTURE, ii. 322) by sowing. Suckers afford the strongest and earliest-bearing plants. Grafted filberts are less liable than others to be encumbered by suckers at the root. By the Maidstone growers the best plants are considered to be obtained from layers. These become well rooted in about a twelvemonth, and then, after pruning, are bedded out in the nursery for two or three years. The filbert may be economically grown on the borders of plantations or orchards, or in open spots in woods. It thrives most in a light loam with a dry subsoil; rich and, in particular, wet soils are unsuitable, conducing to the formation of too much wood. Plantations of filberts are made in autumn, in well-drained ground, and a space of about 10 feet by 8 has to be allowed for each tree. Ground good for hops is good also for filberts, according to Williamson, who recommends old woollen rags as the best manure for the latter ("On the Cultivation of the Filbert," *Trans. Hort. Soc.*, iv. 145). In the third year after planting the trees may require root-pruning; in the fifth or sixth they should bear well. The nuts grow in greatest abundance on the extremities of second year's branches, where light and air have

¹ Derived, it has been supposed, from Ang.-Sax. *hærs*, a behest, connected with *hætan* = Germ. *heissen*, to give orders: the hazel-wand was the sceptre of authority of the shepherd chieftain (ποιμήν λαῶν) of olden times. See Grimm, *Gesch. d. deutsch. Sprache*, p. 1016, 1845

² C. the expression "hazel eyes," see *Notes and Queries*, 2d ser., xii. 337, and 3d ser., iii. 18, 39.

³ For derivations of the word see Latham's *Johnson's Dictionary*.

ready access. In 1819, a very productive year, Williamson obtained from 57 trees, mostly not above six years old, and growing on 360 square yards of ground, 2 cwt. of nuts. To obtain a good tree, the practice in Kent is to select a stout upright shoot 3 feet in length; this is cut down to about 18 inches, of which the lower 12 are kept free from outgrowth. The head is pruned to form six or eight stroug offsets; and by judicious use of the knife, and by training, preferably on a hoop placed within them, these are caused to grow outwards and upwards to a height of about 6 feet, so as to form a bowl-like shape. Excessive luxuriance of the laterals may be combated by root-pruning, or by checking them early in the season, and again later, and by cutting back to a female blossom bud, or else spurring nearly down to the main branch in the following spring. In certain conditions of growth the trees may bear almost exclusively male or female flowers, and those produced in the first blossoming are stated (*Gent. Mag.*, 1788, vol. lviii., pt. 1, p. 495) to be female only. The fertilization of the latter may be secured by suspending amongst them a branch with male bloom.

Filbert nuts required for keeping must be gathered only when quite ripe; they may then be preserved in dry sand, or, after drying, by packing with a sprinkling of salt in sound casks or new flower-pots. Their different forms include the Cosford, which are thin-shelled and oblong; the Downton, or large square nut, having a lacinated husk; the white or Wrotham Park filbert; and the red hazel or filbert, the kernel of which has a red pellicle. The last two, on account of their elongated husk, were by Willdenow distinguished as a species, under the name *Corylus tubulosa*. Like these, apparently, were the nuts of Abella, or Avella, in the Campania (*cf. Fr. avellane*, filbert), said by Pliny to have been originally designated "Pontic," from their introduction into Asia and Greece from Pontus (see *Nat. Hist.*, xv. 24, xxiii. 78). Cob-nuts are short and roundish, and have a thick and strong shell. Hazel-nuts, under the name of Barcelona or Spanish nuts, are largely exported from France and Portugal, and especially Tarragona and other places in Spain. They afford 60 per cent. of a colourless or pale-yellow, sweet-tasting, non-drying oil, which has a specific gravity of 0.92 nearly, becomes solid at -19° C. (Cloez), and consists approximately of carbon 77, and hydrogen and oxygen each 11.5 per cent. Hazel nuts formed part of the food of the ancient lake-dwellers of Switzerland and other countries of Europe (see Keller, *Lake Dwellings*, trans. Lee, 2d ed., 1878). By the Romans they were sometimes eaten roasted. Kaltenbach (*Pflanzenfeinde*, pp. 633-38, 1874) enumerates ninety-eight insects which attack the hazel. Among these the beetle *Balaninus nucum*, L., the nut-weevil, seen on hazel and oak stems from the end of May till July, is highly destructive to the nuts. The female lays an egg in the unripe nut, on the kernel of which the larva subsists till September, when it bores its way through the shell, and enters the earth, to undergo transformation into a chrysalis in the ensuing spring. The leaves of the hazel are frequently found mined on the upper and under side respectively by the larvæ of the moths *Lithocolletis coryli*, Nic., and *L. Nieclii*, Sta. The tom-tit has been observed to pass over the filbert whilst destroying other nuts (Darwin, *Anim. and Pl.*, ii. 231). Parasitic on the roots of the hazel is found the curious leafless *Lathraea squamosa*, or Toothwort, of the natural order *Orobanchaceæ*.

The Hebrew word *haz*, translated "hazel" in the authorized version of the English Bible (Gen. xxx. 37), is believed to signify "almond" (see Kittó, *Cycl. of Bibl. Lit.*, ii. 869, and iii. 811, 1864). A belief in the efficacy of divining-rods of hazel for the discovery of concealed objects is probably of remote origin (*cf. Hosea*, iv. 12). G. Agricola, in his treatise *Vom Bergwecken* (pp. xxix.-xxxii., Basel, 1557), gives an account, accompanied by a woodcut, of their employment in searching for mineral veins. By certain persons, who for different metals used rods of various materials, rods of hazel, he says, were held serviceable simply for silver lodes, and by the skilled miner, who trusted to natural signs of mineral veins, they were regarded as of no avail at all. The virtue of the hazel wand was supposed to be dependent on its having two forks; these were to be grasped in the fists, with the fingers uppermost, but with moderate firmness only, lest the free motion of the opposite end downwards towards the looked-for object should be interfered with. According to Cornish tradition, the divining or dowsing rod is guided to lodes by the pixies, the guardians of the treasures of the earth. By Vallemont, who wrote towards the end of the 17th century, the divining-rod of hazel, or "baguette divinatoire," is described as instrumental in the pursuit of criminals. The Jesuit Vanière, who flourished in the early part of the 18th century, in the *Procedium Rusticum* (pp. 12, 13, new ed., Toulouse, 1742) amusingly relates the manner in which he exposed the chicanery of one

who pretended by the aid of a hazel divining-rod to point out hidden water-courses and gold. The burning of hazel nuts for the magical investigation of the future is alluded to by Gay in *Thursday, or the Spell*, and by Burns in *Halloween*. The hazel is very frequently mentioned by the old French romance writers. The *Corylus rostrata* and *americana* of North America have edible fruits like those of *C. Avellana*. The Witch Hazel is the species *Hamamelis virginica* (see vol. ii. p. 320), of the natural order *Hamamelidææ*, the astringent bark of which is used in medicine.

Bot.*, viii. 170, 1868; Masters, *Vegetable Teratology*, Ray Soc., 1869; J. D. Hooker, *Student's Flora*, pp. 363-4, 2d ed., 1878. (F. H. E.)

HAZEL-HEN. See GROUSE.

HAZLETON, a post-borough of Luzerne county, Pennsylvania, U.S., is situated about 80 miles N.N.W. of Philadelphia. Owing to its elevated and healthy situation, its agreeable climate, and the facilities afforded by its railway connexions with other districts, it has become a favourite and fashionable health-resort in summer. The manufactures include both iron and timber; and a part of the rolling-stock of the Lehigh Valley Railway is made in the town. There are several valuable coal-mines in the vicinity. The population in 1860 was only 1707; in 1870 it was 4317, and since then it has considerably increased.

HAZLITT, WILLIAM (1778-1830), one of the most eminent of English critics, was born April 10, 1778, at Maidstone, where his father was minister of the Presbyterian congregation. He was educated privately, and afterwards at the Unitarian College at Hackney, where he first began to speculate upon metaphysical subjects. Feeling disinclined to enter the dissenting ministry, he returned to Wem in Shropshire, where his father had in the meantime settled, and there led an idle and desultory life until, about 1802, he determined upon becoming a painter. Metaphysics and art continued his joint passion throughout his life. It was his singular lot to be animated by an equal enthusiasm for two of the most dissimilar fields of human effort, in neither of which was he capable of achieving eminence, and yet, by a combination of the qualities proper to both, to obtain the most distinguished success in another sphere which he only entered by accident. The secret of his distinction as a critic is the union in him of the metaphysician's acuteness with the painter's eye for colour and substance. Nowhere else is abstract thought so picturesquely bodied forth by concrete illustration. He commenced the practice of painting in London, where his elder brother had already acquired some reputation as an artist, and soon found his way into literary and artistic circles, becoming especially intimate with Lamb, Hunt, and Godwin. Previously to this he had (January 1798) been powerfully influenced by Coleridge, who had come to preach in his father's neighbourhood, and of whose conversation and general demeanour he has left a most vivid picture. His professional painting did not prosper, and little remains of it except a few portraits; but in 1805 he published his *Essay on the Principles of Human Action*, which had occupied him at intervals for six or seven years. This work, further defined by the author as an argument in favour of the natural disinterestedness of the human mind, was preferred by him to all his other writings, but never attracted any attention from the public. In 1807 appeared a most useful abridgment of Abraham Tucker's *Light of Nature Pursued*, and a clever but fallacious attempt to invalidate the natural law established in Malthus's *Essay on Population*. In the following year he married Sarah, sister of Dr Stoddart, well known for his connexion with the journalism of the day, a woman of literary tastes and great strength of character, but cold, formal, and utterly uncongenial to him. No man indeed could well be less adapted for domestic life than Hazlitt, whose habits, notwithstanding his exemplary sobriety, were most irregular.

whose temper was fitful and moody, and the intensity of whose passions rendered him for the time insensible to the feelings and rightful claims of those who might stand in the way of their gratification. The dissolution of the ill-assorted union was nevertheless deferred for fourteen years, during which much of his best literary work had been produced. After three or four years, during which he almost disappears from observation, he came forward prominently as a writer in the *Examiner* and as a lecturer at the Surrey Institution, bringing out in rapid succession his *Round Table*, a collection of essays on literature, men, and manners, his *View* of the contemporary English stage, and his lectures on the poets, the English comic writers, and the dramatic literature of the age of Elizabeth. By these works, together with his *Characters of Shakespeare's Plays* (1817), and his *Table Talk* (1821), his reputation as a critic and essayist will mainly be sustained. Next to Coleridge, Hazlitt was perhaps the most powerful exponent of the dawning perception that Shakespeare's art was no less marvellous than his genius; and Hazlitt's criticism did not, like Coleridge's, remain in the condition of a series of brilliant but fitful glimpses of insight, but was elaborated with steady care. His lectures on the Elizabethan dramatists performed a similar service for the earlier, sweeter, and simpler among them, such as Dekker, till then unduly eclipsed by later writers like Massinger, better playwrights but worse poets. Treating of the contemporary drama, he successfully vindicated for Edmund Kean (whom, however, he had at first disparaged) the high place which he has retained as an actor; while his criticisms on the English comic writers and men of letters in general are masterpieces of ingenious and felicitous exposition, though rarer, like Coleridge's, penetrating to the inmost core of the subject. As an essayist Hazlitt is even more effective than as a critic, for this style of composition allows more scope to the striking individuality of his character. Being enabled to select his own subjects, he escapes dependence upon others either for his matter or his illustrations, and presents himself by turns as a metaphysician, a moralist, a humorist, a painter of manners and characteristics, but always, whatever his ostensible theme, deriving the essence of his commentary from his own bosom. This combination of intense subjectivity with strict adherence to his subject is one of Hazlitt's most distinctive and creditable traits. Intellectual truthfulness is a passion with him. He steeps his topic in the hues of his own individuality, but never uses it as a means of self-display. The first reception of these admirable essays was by no means in accordance with their deserts. Hazlitt's political sympathies and antipathies were vehement, and he had taken the unfashionable side. The *Quarterly* attacked him with deliberate malignity, stopped the sale of his writings for a time, and blighted his credit with publishers. He had become estranged from his early friends, the Lake poets, by what he uncharitably but not unnaturally regarded as their political apostasy; as well as by an escapade of his own, obscurely related, but apparently not creditable. His inequalities of temper separated him for a time even from Leigh Hunt and Charles Lamb, and on the whole the period of his most brilliant literary success was that when he was most soured and broken. Domestic troubles super-vened; his marriage, long little more than nominal, was dissolved in consequence of the infatuated passion he had conceived for a servant girl, a most ordinary person in the eyes of every one else. It is impossible to regard Hazlitt as a responsible agent while he continued subject to this influence. His own record of the transaction, published by himself under the title of *Liber Amoris, or the New Pygmalion* (1823), is a most remarkable psychological curiosity, and one of the most signal examples extant of the power of

genuine passion, not merely to palliate what is wrong, but to dignify what is ridiculous. "His idolatry," says Mrs Jameson, "in its intense earnestness and reality assumes something of the sublimity of an act of faith." The business-like dissolution of his marriage under the law of Scotland is related with amazing naïveté by the family biographer. Rid of his wife and cured of his mistress, he shortly afterwards astonished his friends by marrying a widow. "All I know," says his grandson, "is that Mrs Bridgewater became Mrs Hazlitt." They travelled on the Continent for a year, and then parted never to meet again. Hazlitt's study of the Italian masters during this tour, described in a series of letters contributed to the *Morning Chronicle*, had a deep effect upon him, and perhaps conducted to that intimacy with the cynical old painter Northcote which, shortly after his return, engendered a curious but eminently readable volume of conversations with him. The respective shares of author and artist are not always easy to determine. During the recent agitations of his life he had been writing essays, collected in 1826 under the title of *The Plain Speaker*; others subsequently written were published after his death. They are in no respect inferior to his earlier performances. *The Spirit of the Age* (1825), a series of criticisms on the leading intellectual characters of the day, reveals that he was less qualified to assign their true place to contemporaries than to revise the verdicts of the past, but is in point of style perhaps the most splendid and copious of his compositions. It is eager and animated to impetuosity, with no trace of carelessness or disorder. He now undertook a work which was to have crowned his literary reputation, but which can hardly be said to have even enhanced it—*The Life of Napoleon* (1828–30). The undertaking was at best premature, and was inevitably disfigured by partiality to Napoleon as the representative of the popular cause, excusable and even becoming in a Liberal politician writing in the days of the Holy Alliance, but preposterous now that the true tendencies of French imperialism are recognized. Owing to the failure of his publishers Hazlitt received no recompense for this laborious work. Pecuniary anxieties and disappointments may have contributed to hasten his death, which took place on September 18, 1830. Charles Lamb was with him to the last.

With many serious defects both on the intellectual and the moral side, Hazlitt's character in both had at least the merit of sincerity and consistency. He was a compound of intellect and passion, and the refinement of his critical analysis is associated with vehement eloquence and glowing imagery. He was essentially a critic, a dissector, and, as Bulwer justly remarks, a much better judge of men of thought than of men of action. But he also possessed many gifts in no way essential to the critical character, and transcending the critic's ordinary sphere. These, while giving him rank as an independent writer, frequently perturbed the natural clearness of his critical judgment, and seduced him into the paradoxes with which his works abound. These paradoxes, however, never spring from affectation; they are in general the sallies of a mind so agile and ardent as to overrun its own goal. His style is perfectly natural, and yet admirably calculated for effect. His diction, always rich and masculine, seems to kindle as he proceeds; and when thoroughly animated by his subject, he advances with a succession of energetic, hard-hitting sentences, each carrying his argument a step further, like a champion dealing out blows as he presses upon the enemy. Although, however, his grasp upon his subject is strenuous, his insight into it is rarely profound. He can amply satisfy men of taste and culture; he cannot, like Coleridge or Burke, dissatisfy them with themselves by showing them how much they would have missed without him. He belongs to the

class of critics that exhibits the beauties of an author, rather than to the class that reveals them. He was somewhat backward in appreciating contemporary merit; he venerated Coleridge's intellect, but his estimate of his poetry is ridiculously low; his review of Shelley's posthumous poems, though rhetorically fine, is critically poor; and he did little to vindicate the fame of Keats. As a moralist and observer of manners his chief merit consists in the extreme felicity of his occasional observations. But all shortcomings are forgotten in the genuineness and fervour of the writer's self-portraiture, and the bold relief in which he stands out from the crowd of mankind. The intensity of his personal convictions causes all he wrote to appear in a manner autobiographic. Other men have been said to speak like books, Hazlitt's books speak like men. To read his works in connexion with Leigh Hunt's and Charles Lamb's is to be introduced into one of the most attractive of English literary circles, and this alone will long preserve them from oblivion.

The most copious source of information respecting Hazlitt is the biography by his grandson (1867), a medley rather than a memoir, yet full of interest. A slight but appropriate sketch had previously been prefixed by his son to the posthumous essays published in 1836, accompanied by elegant but partial estimates of his intellectual character by Bulwer and Talfourd. Valuable biographical particulars have been preserved in Barry Cornwall's memoirs of Lamb, and in the reminiscences of Mr P. G. Patmore, Hazlitt's most intimate associate in his latter years. A full bibliographical list of his writings, with a collection of the most remarkable critical judgments upon them from all quarters, has been tastefully and industriously prepared by Mr Alexander Ireland (1868). (R. G.)

HEAD, SIR EDMUND WALKER, BART., (1805-1868), a popular writer on art, was born in 1805 at Wiarton Place, near Maidstone in Kent. He was educated at Winchester school and Oriel College, Oxford, and taking his degree with first-class honours in classics, he became in 1827 fellow of Merton College, and in 1834 university examiner in classics. Two years later he married; and on his father's death in 1838, he succeeded to the baronetcy as eighth baronet. His services as poor-law commissioner, to which post he was appointed in 1841 after three years as assistant-commissioner, procured for him in 1847 the office of lieutenant-governor of New Brunswick, whence he passed in 1854 to the governor-generalship of Canada, which he retained till 1861. The following year, having returned to England, Head was nominated a civil-service commissioner. In 1857 he was sworn of the Privy Council, and in 1860 was decorated as K.C.B., while in the course of his career he received the degrees of D.C.L. at Oxford and LL.D. at Cambridge. He died in London, January 28, 1868.

Sir Edmund Head wrote the article "Painting," in the *Penny Cyclopædia*; *A Handbook of the Spanish and French Schools of Painting*, 1845; *Shall and Will, or two chapters on future Auxiliary Verbs*, 1856; and *Ballads and other Poems, original and translated*, 1868. He also edited *A Handbook of Painting of the German, Flemish, Dutch, Spanish, and French Schools*, 1854. His translation from the Icelandic of *Viga Glum's Saga* appeared in 1865.

HEAD, SIR FRANCIS BOND, BART. (1793-1875), soldier, traveller, and author, son of James Roper Head of the Hermitage, Kent, was born there January 1, 1793. He served with the Royal Engineers at the battles of Waterloo and Fleurus, and when he retired from the army he had risen to the rank of major. In 1825 he accepted the charge of an association formed to work the gold and silver mines of Rio de la Plata. In connexion with this enterprise he made several rapid journeys across the Pampas and among the Andes, his *Rough Notes* of which, published in 1826, and written in a clear and spirited style, obtained for him the name of "Gallop Head." In 1835 he was appointed governor of Upper Canada, where he manifested similar energy in dealing with the discontents from which the colony was at that time suffering. He resigned his

office in 1837, and in recognition of his services he was in 1838 created a baronet. The narrative of his administration in Upper Canada was published by him in 1839. In 1867 he became a privy councillor. He died at his residence at Croydon, July 20, 1875. Some time previously a pension of £100 per annum was conferred upon him for his "services to literature."

Sir Francis Head was the author of a considerable number of works, chiefly of travel, written in a clever, amusing, and graphic fashion, and displaying both acute observation and genial humour. Besides those already mentioned, his principal works, which have all gone through more than one edition, are *Bubbles from the Brunnen of Nassau*, 1833; *Life of Bruce*, 1844; *The Emigrant*, 1846; *Stokers and Pokers*, 1850; *The Defenceless State of Great Britain*, 1850; *A Faggot of French Sticks*, 1851; *A Fortnight in Ireland*, 1852; *Descriptive Essays*, 1856; *The Horse and his Rider*, 1860; *The Royal Engineer*, 1870.

HEAD, SIR GEORGE (1782-1855), brother of the preceding, was born in 1782. He was educated at the Charterhouse. In 1808 he received an appointment in the commissariat of the British army in the Peninsula, where he was a witness of many exciting scenes and important battles, of which he gave an interesting account in "Memoirs of an Assistant Commissary-General" attached to the second volume of his *Home Tour*, published in 1837. In 1814 he was sent to America to take charge of the commissariat in a naval establishment on the Canadian lakes, and he subsequently held appointments at Halifax and Nova Scotia. Some of his Canadian experiences were narrated by him in *Forest Scenery and Incidents in the Wilds of North America*, published in 1829. In 1831 he received the honour of knighthood. He published in 1835 *A Home Tour through the Manufacturing Districts of England*, and in 1837 a sequel to it, entitled *A Home Tour through various parts of the United Kingdom*. Both works are amusing and instructive, but his *Rome, a Tour of Many Days*, published in 1849, is somewhat dull and tedious. He also contributed several articles to the *Quarterly Review*, and translated *Historical Memoirs of Cardinal Pacca*, 1850, and the *Metamorphoses of Apuleius*, 1851. He died in London, May 2, 1855.

HEARNE, SAMUEL (1745-1792), an English explorer, was born at London in 1745. At the age of eleven he entered the Royal Navy as midshipman in the vessel of Lord Hood, but at the conclusion of the war he took service with the Hudson's Bay Company as quartermaster. In 1768 he was appointed to examine portions of the coast of Hudson's Bay with a view to the improvement of the cod-fishing, when he executed his task with such ability that it was resolved to employ him in the discovery of the north-west passage, and of certain mines of copper whose existence was asserted by the Indians. His first attempt, upon which he set out on November 6, 1769, was unsuccessful owing to the desertion of the Indians; and his second, entered upon on 23d February 1770, was by the breaking of his quadrant likewise rendered abortive; but in his third expedition, upon which he started in December 1770, he was completely successful, as he not only discovered the existence of copper on the banks of what is now known as Coppermine river, but traced the course of that river till it joined the Arctic Ocean. After an absence of eighteen months and twenty-three days he arrived at Fort Churchill, of which he was subsequently promoted to be the governor. He returned to England in 1787, and died there in 1792. An account of his journeys from Prince of Wales Fort to the Northern Ocean was published posthumously in 1795.

HEARNE, THOMAS (1678-1735), an English antiquary, was born in 1678 at Littlefield Green, in the parish of White Waltham, Berkshire, where his father, the parish clerk, in payment of the rental of the vicarage house in which he lived, taught ten boys yearly. Thomas, after

receiving the rudiments of education from his father, was sent by the kindness of a gentleman to the free school of Bray, "on purpose to learn the Latin tongue." This gentleman in 1695 took him into his house, and his education was continued at Bray till the Easter of 1696, when he was sent to study at Edmund Hall, Oxford. There his diligence and scholarship attracted the attention of Dr John Mill, the editor of the Greek Testament with various readings, who employed him to compare several MSS. Hearne took the degree of B.A. in 1699, and on account of the reputation he had acquired for his knowledge of books he was in 1701 appointed assistant-keeper of the Bodleian Library. There at his own option he set himself diligently to correct the catalogue, and prepared an appendix which was afterwards incorporated in the new catalogue without acknowledgment. His interest in the antiquarian treasures of the library induced him to refuse many valuable preferments, and in 1712 he was appointed second keeper, with the stipulation made by himself that he should also be janitor, so as to obtain access to the library at any time he pleased. In 1714 or 1715 he was elected architypographus and esquire beadle of civil law in the university, but, an objection being taken to his holding this office along with that of second librarian, he resigned it in the November following. In January 1716 he was compelled, on account of his refusal to take the oaths to the Government, to resign also his appointment of librarian, but he continued to reside principally at Oxford, where he occupied himself chiefly in preparing for publication the works of old English authors. His injudicious and inappropriate insertion of Jacobite sentiments in his prefaces awakened, however, the hostility of the university magnates, and subjected him to several prosecutions. He died 10th June 1735. Though Hearne was somewhat indiscriminate in his antiquarian taste, and rambling and desultory in his style of composition, his persevering diligence and minute accuracy enabled him to do valuable service in bibliography.

His publications were nearly all printed by subscription at Oxford. The principal of them are—*Ductor Historicus; Reliquiæ Bodleianæ*; an edition of *Livy*; *Spelman's Life of Alfred the Great*; *Leland's Itinerary*; *Leland's Collectanea; Acta Apostolorum; Titi Livii Foro-Julianis Vita Henrici Quinti, Regis Angliæ; Aluredi Beverlaccensis Annales; Gulielmi Roperi Vita D. Thomæ Mori Equitis Aurati; Gulielmi Camdeni Annales Rerum Anglicarum et Hibernicarum regnante Elizabetha; Gulielmi Newborghensis Historia; Thomæ Sprotti Chronica; A Collection of Curious Discourses written by Eminent Antiquaries upon English Antiquities; Roberti de Avesbury Historia de Mirabilibus Gestis Edwardi III.; Johannis de Fordun Scotiechronicon Genuinum; History and Antiquities of Glastonbury; Robert of Gloucester's Chronicle; Annals of Dunstable; and Benedict, Abbot of Peurborough. Most of these have been reprinted. His MSS. were left by him to Dr William Bradford, of whom they were bought by Dr Richard Rawlinson and bequeathed to the Bodleian Library. *Bibliotheca Hearniana, Excerpts from the Catalogue of Thomas Hearne, M.A.*, appeared in 1848. *Reliquiæ Hearnianæ, the remains of Thomas Hearne, of Edmund Hall, being extracts from his MS. diaries, collected with a few notes by Philip Bliss*, was published in two volumes, Oxford, 1857; 2d ed., London, 1869.*

See *Impartial Memorials of the Life and Writings of Thomas Hearne, M.A.*, by several hands, London, 1736; *Lives of Leland, Hearne, and Wood*, Oxford, 1772; and *Nichols's Literary Anecdotes. Letters addressed to T. Hearne*, edited by T. Ouvry, were privately printed at London, 1874. Bliss's copy of *The Life of T. Hearne*, with copious notes, is in the library of the British Museum.

HEART, DISEASES OF THE, form a large proportion of the most serious disorders that afflict mankind, in youth as well as in advanced life. For the structure and functions of the organ the reader is referred to **ANATOMY** and **PHYSIOLOGY**.

In the early ages of medicine, the absence of correct anatomical, physiological, and pathological knowledge prevented diseases of the heart from being recognized with any certainty during life, and almost entirely precluded them from becoming the objects of medical treatment. But no sooner did Harvey (1628) publish his discovery of the circulation of the blood, and its dependence on the heart

as its central organ, than derangements of the circulation began to be recognized as signs of disease of that central organ. The earliest indications of this important step in the diagnosis of these diseases are to be found in the instructive records contained in the writings of the great pathologists of the beginning of the 18th century, of whom the chief in this respect are Lancisi, Morgagni, Senac, and Meckel. There is, however, a limit to the information obtainable in this way; and, though its range has been largely increased in our day by the invention of such instruments as the sphygmograph and cardiograph, &c., it was very easily reached in those early times, when men had only their unaided senses to depend upon, and but little experience to guide them. We need not wonder, then, that after the first great step was taken there was but little further progress made, and medicine had to wait till the beginning of another century, when Corvisart (1806) first made practical use of Auenbrugger's (1761) invention of percussion to determine the size of the heart, enlargement of that organ bulking largely in those days as a substantive disease. Corvisart was also in the habit of listening to the sounds made by the heart, and he may therefore be regarded as the first practical exponent of our modern methods of physical exploration, though scarcely as their founder. For as Auenbrugger invented percussion, so Laennec (1819) was undoubtedly the first to make a scientific application of mediate auscultation to the diagnosis of diseases of the chest, and it is to him we trace all the benefits derived from this method of inquiry, though it is to Bouillaud (1824) that we are chiefly indebted for its extension to the diagnosis of diseases of the heart; while it is to the clinical experience, and above all to the practical experiments, of James Hope (1832) that we owe much of that precision we have now attained in our diagnosis of those diseases from abnormalities in the sounds produced during the cardiac movements; just as we have learned from M. Forget (1851) the doctrine of retro-dilatation, which rightly interpreted is capable of greatly informing us as to the origin and progress of heart disease, and from William Stokes (1854) some instructive views on defective heart power as a cause of certain symptoms simulating disease of the brain, which have proved most valuable and suggestive in the diagnosis of diseases of the heart as well as in their treatment.

The half dozen works just alluded to by no means exhaust the literature of this subject during the past ages, but each of them marks an era, and by their means we may readily trace the progress of cardiac diagnosis during the 130 years intervening between Lancisi and Stokes; but during the twenty odd years that have since elapsed the literature of this subject has become so unusually copious and exhaustive that it would occupy too much space merely to enumerate the authors' names. Fortunately this further development need not concern us here.

As in former so in recent times the progress made in the diagnosis of diseases of the heart has been entirely based on physics and on physiology, and the heart is an organ so situated and so connected as to render it singularly amenable to these methods of investigation. Resting on the diaphragm, and projected against the anterior chest-wall, the heart is partly within reach, and is otherwise so completely surrounded on three sides by resonant organs (the lungs) that any change in its position or in its size is readily made out by palpation and percussion, while by listening over the cardiac area—auscultation—we can ascertain whether the valves of the heart remain intact, have an unusual strain thrown upon them, or have been rendered incompetent by disease.

As the four openings of the heart lie so close together that a superficial area of half a square inch includes a part

of each, it is only by taking advantage of certain well-known laws regulating the conduction of sound that we are able to differentiate the sounds produced at each of these openings respectively, and to assign to each a definite position on the chest-wall, where it is heard at its maximum intensity. Physiology, on the other hand, teaches us that each individual cardiac pulsation, the time of which is marked for us by that impulse against the chest-wall of which we are all more or less conscious, consists of alternate acts of contraction and dilatation affecting the four cavities of the heart. Some of these acts precede this impulse, some accompany it, and others follow it, and the relation of any sound produced within the heart to these physiological acts is termed its rhythm.

The functional perfection of the heart is thus easily determined by ascertaining that it is of a normal size, that its impulse is neither too strong nor too weak, and that its sounds are normal when listened to, each in its own position of maximum intensity. When these conditions are present, any abnormal cardiac phenomena, such as palpitation, irregular action, &c., are to be regarded as entirely due to abnormal innervation, and not to any actual disease of the heart. On the other hand functional imperfection is readily detected by the occurrence of any abnormality in the phenomena already referred to, especially if accompanied by a blowing sound instead of the usual valve sound in any of the normal auscultatory areas. And an intelligent appreciation of these facts, together with a correlation of the physical with the physiological phenomena, that is, a correct determination of the rhythm of the sounds heard, enables us to ascertain with certainty, not only the valve implicated, but also the mode in which the lesion has affected or is likely to affect the heart and through it the circulation. Having found the heart to be functionally imperfect, we have two alternatives presented to us—either the valves are incurably deformed from previous disease, or they are merely functionally imperfect from over-distention of the cardiac cavities, a state of matters which may arise from various causes, and which is always susceptible of great relief and very often of perfect cure.

The great function of the heart is to keep up such a pressure within the arterial section of the vascular canals as will suffice for the maintenance of the circulation and of all the organic functions of the body dependent upon it. The tendency, however, of all the extrinsic forces connected with the circulation is to equalize the blood pressure throughout the vascular system, and so to bring the circulation to a stand-still; and indeed it is in this way that death at last occurs; whether it happen suddenly or slowly the cause is still the same—cessation of the circulation brought about by equalization of the blood pressure throughout the whole of the vascular system, or, as it may be otherwise put, from decline of the arterial (aortic) blood pressure.

Valvular lesions of the heart, however produced, tend, as may be readily understood, to neutralize the cardiac function and to lower the arterial blood pressure, either by permitting an unnatural escape of the blood backward (regurgitation) or by obstructing its onward flow (obstruction). And this action is further intensified by the interference with the cardiac nutrition which necessarily results, first of all directly, from the heart being flushed with blood at a low pressure, and secondly indirectly, from the imperfect performance of all those functions, such as digestion, &c., upon which the formation of healthy blood depends, arising from the same cause.

Valvular disease thus gives the heart more work to do, while it takes from it the power of doing it, putting the organ in a vicious circle. In this way curable disease if neglected may readily lapse into incurability, while to incurable disease there can be but one ending, though, apart

from such accidents as embolism or asystole from violent emotion or exertion, that is neither so sudden nor so speedy as is commonly supposed, and indeed usually occurs from gradual asthenia, often accompanied by dropsy, and preceded by a life of more or less active exertion, averaging in many cases not less than twenty years from the primary onset of the disease. During this comparatively long period the disease may have been entirely mute; that is, the valve lesion has progressed so slowly from its trifling commencement that the residual accumulation in the cavity primarily affected has gone on *guttatim*, and has spread itself backwards over the other sections of the circulation in the same gradual manner, the resulting dilatation being so immediately followed by compensating hypertrophy that the sufferer has never been aware of any derangement of his functions. A time comes at last, however, when, from a failure of nutrition due to physical causes, the increase in the heart's bulk ceases to be muscular, it becomes fibrous; then indeed the disease is no longer mute, serious rupture of the compensation sets in, and all that art can do is to make the inevitable declension as gradual as possible. Up to this period any accidental rupture of the compensation, which readily enough occurs from over-exertion, imperfect nutrition from any cause, or from any feverish attack, is as a rule perfectly amenable to appropriate treatment, though the restored compensation is always less stable than it had been previously.

Ruptured compensation is often attended by very alarming symptoms, such as great general dropsy and extreme irregularity of the heart's action, but the true measure of the patient's danger lies less in these symptoms than in the condition of the cardiac muscle, and in the circumstances which threaten asystole, that is, arrest of the heart's action.

If in early times the diagnosis of diseases of the heart was a matter of great difficulty, this seemed of less importance as their treatment was so hopeless. "A mesure qu'on pénètre," says Senac, "dans les maladies du cœur, la médecine paraît plus stérile; que peut-on espérer des médicaments, par exemple, dans les dilatations du cœur?" But modern science, which has rendered the heart so accessible from all sides that there is nowadays probably no organ of the body whose diseases can be so readily detected or so accurately discriminated, has not only pointed out the true source of danger in these diseases, but has also put into our hands a remedy by which some are cured who were formerly thought incurable, while many incurables have their downward progress so successfully arrested that they feel themselves to be practically cured. And yet DIGITALIS (*q.v.*) was all but unknown 100 years ago, while so little was known of its real action—*ratio medendi*—that within the last thirty years a living author wrote that the use of digitalis as a diuretic in heart disease was quite "indefensible," as "the failing heart is absolutely incapable of sustaining the depressing influence of the drug." Nowadays we know digitalis to be the only drug that can be relied on for increasing the power of the heart's contractions, and it also slows them,—the result being that the blood pressure is increased throughout the whole arterial system, and that, time being given for the heart itself to be flushed by blood at an increased pressure, its nutrition is improved. The heart not only acts more powerfully under the immediate influence of the drug, but it becomes more able to act, so that by and by the drug may be left off; though indeed, should the muscular degeneration determinately threaten a rapid progression, tonic doses of the drug may be safely given daily for many years continuously, in spite of all our forefathers' croaking as to the dangers of accumulation. But however marvellous the effects of tonic doses of digitalis may be, the virtues of the drug in larger doses are even more wonderful in appropriate cases, for by means of large doses the skilled physician has it in his power

permanently to contract many dilated hearts, and so to cure what seemed an incurable disease not only to Senac but even to many of his more modern successors.

There are many other drugs employed in the treatment of diseases of the heart, but there is no other deserving of special mention. Other medicines are employed to relieve pain, aid digestion, dispel flatulence, unload the bowels, improve the blood, or simply as general tonics, and may be catalogued as morphia, chloroform, belladonna, pepsine, asafoetida, aloes, rhubarb, iron, &c.

ANGINA PECTORIS (*q.v.*) is a painful disease of the heart which has been already described. *Palpitation* is an extremely rapid and sometimes forcible action of the heart. *Irregular and Intermittent Action* are sufficiently described by their names; irregular action may be tumultuous or so peculiar as to deserve the name of a veritable *delirium cordis*; intermission consists in the dropping of a beat every second, third, or fourth time, or seldomer. Sometimes the intermission only applies to the pulse, the heart acting regularly, and is caused by that particular systole not being forcible enough to propel the blood to the periphery; occasionally we have two beats of the pulse and then an intermission, constituting what has been termed a *pulsus bigeminus*, or the rhythm of the intermission may be even more varied. All these forms of perverted action of the heart may accompany valvular lesions, or they may occur in hearts whose valves are sound; the walls of such hearts are, however, almost invariably more or less feeble, imperfectly nourished, and the blood often poor and watery. They are rarely indicative of any real danger, though sufficiently troublesome and alarming to the sufferer; they arise from abnormal innervation, and are part of the penalties we pay for our present state of organization. We could enjoy nothing if we could not also suffer; and the blush of sensitiveness, the quickened pulse of affection, are paid for by the throb of anxiety, and the fatal inhibition of the heart's action due to overwhelming emotion. Most of these cases, however, own a much more ignoble origin: a flatulent distention of the stomach, a crapulous dyspepsia, the abuse of alcohol and tobacco, &c., are frequent sources of nervous heart trouble, so frequent that in some parts where young men most do congregate the tobacco-heart

especially is quite a proverbial ailment. Overwork, worry, or excess of any kind is sufficient to bring on heart trouble of this character, as we can readily understand when we reflect that the heart does about one-fifth of the whole mechanical work of the body—a work equivalent to raising its own weight over 13,000 feet an hour; that it takes its rest only in short snatches as it were, its action as a whole being continuous; and that it must necessarily be the earliest sufferer from any improvidence as regards nutrition,—mental emotion being in this respect quite as potential a cause of constitutional bankruptcy as the most violent muscular exertion. Fortunately, to a skilled physician there is no difficulty of determining the true nature of these cases, and they are all more or less amenable to appropriate treatment. *Syncope*, or fainting, is an affection somewhat similar to those just described; it essentially consists in an emotional inhibition of the cardiac systole, so that the blood pressure within the brain falls below that necessary for the maintenance of consciousness; as the heart's action fortunately does not in these cases entirely cease, the best plan is to favour the flow of blood to the head by maintaining the sufferer with a lowered and slightly depending head until the effects of the momentary inhibition have passed off. The inflammatory affections of the heart, *Carditis*, *Endocarditis*, and *Pericarditis* are most important and serious affections, but their history and treatment are more suited for a work on practice of physic, in any of which full information regarding them may be found. They are mainly rheumatic and gouty in character, and they are to be regarded as varieties of these diseases; the mere fact of their affecting the heart is of but little consequence as to their immediate result, however important it may by and by become from the valvular lesions to which they so often give rise. There are but few exceptions to this rule, and amongst them are those rare cases in which acute endarteritis blocks the coronary vessels and gives rise to fatal angina. *Fatty Degeneration* of the heart, which bulks so largely in the popular mind as a cause of sudden death, is an almost hypothetical lesion of most infrequent occurrence, probably never found apart from disease of the coronary arteries, impossible of diagnosis, and very rarely of itself proving suddenly fatal. (G. W. B.)

H E A T

By SIR WILLIAM THOMSON.

Entered according to Act of Parliament of Canada, in the year 1880, by WILLIAM THOMSON, Knt., Glasgow, Scotland, in the office of the Minister of Agriculture.

H EAT is a property of matter which first became known to us by one of six very distinct senses.

§ 1. *Sense of Heat.*—The sense of touch, as commonly meant, has two distinct objects—force and heat. If a person stretches out his hand till it meets anything solid, or holds it out while something solid is placed upon it, he experiences a sensation of force. He perceives resistance to the previous motion of his hand in one case, in the other case the necessity of resisting to prevent his hand from being forced downwards; the immediate object of this perception in each case is force.¹ But there is another very distinct sensation, that of heat or cold, which he may or may not

¹ The sense of smoothness and roughness to which physiologists have sometimes given the special name "tactile sense" is as clearly a sense of force as is what they call the muscular sense. The sense of roughness is a sense of force at places of application distributed over the skin of the finger, while in the muscular sense of force the place of application on a larger scale is distinguished by the position of the hand perceiving the force. The internal mechanism of tissue and nerves in one case and that of muscles in the other, through which the perception of places of application of force is obtained, are no doubt different, but the thing perceived is essentially the same—force—the complete discrimination of which involves magnitude of the force, its place of application, and its direction.

perceive in either of those cases, and which he may also perceive, still by what is commonly called the sense of touch, in other cases even when no sense of force is also experienced. Thus, in the first case, if the solid be a fixed can of warm water, or of iced water, the person perceives a sense of heat or of cold; and, supposing him to have performed the operation with his eyes shut, his mind is informed by the double sense of touch that his hand has met with a hot fixed body or a cold fixed body: in the other case he may perceive that a hot heavy solid, or a cold heavy solid, has been laid upon his hand. But if he dips his hand gently into a can of water, or if he holds it towards a fire, or if he exposes it to a gentle current of air, or waves it about through the air, he perceives heat or cold without any accompanying sense of force.

The earliest scientific thoughts respecting these sensations of heat and cold must have led to the true conclusion that there is some property of external matter on which the sensations depend, and a little advance into the natural philosophy of the subject has suggested and proved that this property is also possessed by the living body, and that the sensation of heat or cold in the hand, in the instances

referred to above, depends on the change produced in the hand in respect to this property by a change of circumstances which preceded the sensation. We now call heat the property of matter concerned in these sensations, and temperature a certain variable quality of matter varying according to its temporary condition in respect to heat.

In the strictest modern scientific language (compare § 3 below) the word heat is used to denote something communicable from one body or piece of matter to another, and temperature a definite variable quality of matter, varying generally in any particular piece of matter when heat is communicated to it or taken from it, varying also as we shall see (§§ 8 and 9 below; also THERMODYNAMICS) in consequence of operations which can take place within the body itself, or which may be performed upon it from without, but which cannot be described as communication of heat to it or drawing off of heat from it.

§ 2. *Latent Heat.*—There are exceptional cases in which temperature does not vary in a mass of matter when heat is communicated to it from, or taken from it, external matter. For instance, when the body is ice at the melting point, heat communicated to it does not raise its temperature; or if the body be water at the freezing point with ever so small a piece of ice in it (see MATTER, PROPERTIES or), heat taken from it does not cause its temperature to fall; or if the whole mass considered be ice and water well mixed, heat may be either communicated to it or taken from it without altering its temperature; or if the body be water at the boiling point in the open air, heat very slowly communicated to it in however great quantities does not raise its temperature sensibly, but causes it to disappear by evaporation from its surface; or if the body be steam in a cylinder with a little water in the bottom and with a frictionless piston above it for roof (fig. 1), under atmospheric pressure, heat taken from it very slowly does not cool it until the whole steam has become condensed into water, and heat communicated to it very slowly does not warm it until the whole water has become evaporated into steam; or if the body be ice (or frozen water), in place of the liquid water of the last case, and if the pressure on the upper side of the piston, instead of atmospheric pressure of about 1033 grammes per square centimetre (14·7 lb per square inch), be anything less than $\frac{3}{5}$ th of a gramme per square centimetre, the same statement will still apply with "ice" substituted for water. Black's celebrated doctrine of latent heat is merely the declaration of a class of phenomena of which the preceding illustrations sufficiently indicate the character. Modern mysticism has been much exercised in respect to the terms sensible heat and latent heat, whether in decrying them, or in continuing to use them, but with aggravating haziness, instead of the clear wrongness of the old doctrine. It has become of late years somewhat the fashion to decry the designation of latent heat, because it had been very often stated in language involving the assumption of the materiality of heat.¹ Now that we know heat to be a mode of motion, and not a

Fig. 1.

material substance, the old "impressive, clear, and wrong" statements regarding latent heat, evolution and absorption of heat by compression, specific heats of bodies and quantities of heat possessed by them, are summarily discarded. But they have not yet been generally enough followed by equally clear and concise statements of what we now know to be the truth. A combination of impressions surviving from the old erroneous notions regarding the nature of heat with imperfectly developed apprehension of the new theory has somewhat liberally perplexed the modern student of thermodynamics with questions unanswerable by theory or experiment, and propositions which escape the merit of being false by having no assignable meaning. There is no occasion to give up either "sensible heat" or "latent heat"; and there is a positive need to retain the term latent heat, because if it were given up a term would be needed to replace it, and it seems impossible to invent a better. Heat given to a substance and warming it is said to be sensible in the substance. Heat given to a substance and not warming it is said to become latent. These designations express with perfect clearness the relation of certain material phenomena to our sensory perception of them. Thus when heat given to a quantity of water warms it, the heat becomes sensible to a hand held in the water. When a basin of warm water and a basin of water and ice are placed side by side, a hand dipped first in one and then in the other perceives the heat. If now the warm water be poured into the basin of ice and water, and stirred for a few seconds of time (unless there is enough of warm water to melt all the ice), the hand perceives no warmth; on the contrary, it perceives that the temperature is the same as it was in the basin of ice and water at the beginning. Thus the heat which was sensible in the basin of warm water has ceased to be sensible in the water that was in that basin, and has not become sensible in the other. It is therefore well said to have become latent.

CALORIMETRY.

§ 3. *Calorimetry by Latent Heat.*—The doctrine of latent heat leads us very smoothly to a most important measurement in thermal science, the measurement of quantities of this wonderful property of matter which we call heat; and this without our knowing anything of what the nature of heat is, —whether it be a subtle elastic fluid, or a state of motion, or possibly some modification of matter related to action of force. Without, in the first place, admitting into our minds any definite idea as to the nature of heat, we may agree to measure quantities of heat by quantities of ice melted into water without change of temperature. Thus if a kilogramme of ice is melted by a large quantity of water at a lukewarm temperature, or by a comparatively small quantity of very hot water, the same quantity of heat has certainly gone from the warm water to the ice in each case, supposing that the result in each case is the ice and warm water left all in a state of ice-cold water. The measurement of quantities of heat, whether thus by the melting of ice, or by any other means, received the name of "Calorimetry," when the essence of heat was supposed to be a fluid, and this fluid called caloric. The name calorimetry is still by general consent retained to designate measurement of quantities of heat, as distinguished from thermometry, or

¹ A hundred years ago those deeper philosophers who in their judgment anticipated, or tended to anticipate, what we now know to be the true theory of the nature of heat, had indeed good grounds to be jealous of even the phrase *latent heat*. Maxwell says—"It is worthy of remark that Cavendish, though one of the greatest chemical discoverers of his time, would not accept the phrase *latent heat*. He prefers to speak of the generation of heat when steam is condensed, a phrase inconsistent with the notion that heat is matter, and objects to Black's term as relating 'to an hypothesis depending on the supposition that the heat of bodies is owing to their containing more or less

of a substance called the matter of heat; and, as I think Sir Isaac Newton's opinion that heat consists in the internal motion of the particles of bodies much the most probable, I chose to use the expression *heat is generated*' (Phil. Trans., 1783, quoted by Forbes). We shall not now be in danger of any error if we use latent heat as an expression meaning neither more nor less than this:—

"DEFINITION.—*Latent heat is the quantity of heat which must be communicated to a body in a given state in order to convert it into another state without changing its temperature.*"—Maxwell's *Theory of Heat*, pp. 72, 73.

the measurement of temperature (§ 10-67). As long as the truth or falsity of the materialistic hypothesis seemed an open question, the word caloric was held to imply the materiality of heat. Thus Davy, after discussing some of the fundamental dogmas of the "Calorists," as he called them, and describing his own experiments, which proved beyond all doubt the falsity of their fundamental hypothesis that heat is matter, varied the statement of his conclusion by saying, "or caloric does not exist." While accepting Davy's conclusion, however, we need not accept this way of stating it; and as most of our best modern writers still use the word calorimetry, and as French writers have, in comparatively recent times, introduced the word "calorie" to designate a unit quantity of heat, it is decidedly convenient still to retain the name caloric to denote definitely the measurable essence of heat. This is convenient scientifically as tending to give precision to language and ideas respecting the two classes of measurement, calorimetry and thermometry; and it has the advantage of leaving the more popular word heat available for that somewhat lax general usage, from which we cannot altogether displace it, in which it may sometimes mean high temperature, as when we speak of great heat, or summer heat, or blood heat, sometimes a measurable quantity of heat, as in the term latent heat, and sometimes a branch of study or science dealing with the transference of heat by conduction and radiation, as in the title of Fourier's great work *Théorie analytique de la Chaleur*, or the whole province of science concerned with heat, including calorimetry and thermometry, and conduction and radiation of heat, and generation of heat, and dynamical relations of heat, as in English titles of separate books such as Dixon's, Balfour Stewart's, and Maxwell's, or of chapters or divisions of larger treatises, such as even the present article.

§ 4. *Calorimetry by Melting of Ice.*—Calorimetry was first practised by means of the melting of ice as explained above, and the first thermal unit, or unit quantity of heat, or "calorie," although not then called caloric, was the quantity of heat required to melt unit weight of ice. This, for example, is the unit on which Fourier founds his reckoning illustratively when he explains the fundamental principles of his theory of the conduction of heat. Ice seems to have been first used for calorimetry by Wilcke, a Swede. For the systematic application of this method for the measurement of quantities of heat in various physical inquiries Laplace and Lavoisier constructed an instrument, the first to which the name of calorimeter was applied, and described it in the memoirs of the French Academy of Sciences for 1780.¹ Though in the hands of Laplace and Lavoisier it gave good results, it had a great inconvenience, which with less careful and less scientific experimenters might lead to great inaccuracies, on account of the water adhering by capillary attraction to the broken ice, instead of draining away from it completely and showing exactly how much ice had been melted. To avoid this evil Sir John Herschel suggested that, instead of draining away the water from the ice, the water and ice should all be kept together, and the whole bulk measured. The diminution of bulk of the whole thus gives an accurate measurement of the quantity of ice melted, because ice melting into water comes to occupy just 91·675 per cent. of its original volume. This suggestion is admirably carried out by Bunsen² in his ice-calorimeter, an instrument possessing also other novel features of remarkable beauty and scientific interest. It is particularly valuable for the measurement

of small quantities of heat. Its inventor, for example, by means of it succeeded in making satisfactory determinations of the specific heats of some of those rarer metals, such as indium, of which only a few grammes have been obtained.

§ 5. *Calorimetry by the Evaporation of Water.*—By another application of Black's doctrine of latent heat, the evaporation of water may be used for calorimetry with great advantage in many scientific investigations. It is used generally in engineering practice, particularly for testing the heating power of different qualities of coal and the economy of various forms of furnaces. The thermal unit, which presents itself naturally in this system, is the quantity of heat required to evaporate unit weight of water when the pressure of the atmosphere as measured by the barometer is of some conventional standard amount, such as that called one atmosphere, or one atm, being that for which the barometer, with its mercury column at zero centigrade (or the temperature at which ice melts), stands at 76 centimetres in the latitude of Paris, 48° 50',³ or at

$$\frac{76 \times (1 + \cdot 00531 \sin^2 48^\circ 50')}{1 + \cdot 00531 \sin^2 l}$$

in any latitude l . This thermal unit (see THERMODYNAMICS) is, according to Regnault's observations, equal to 6·8 times the ice-calorimetric unit.

§ 6. *Thermometric Calorimetry.*—The most prevalent mode of calorimetry in scientific investigation has been hitherto, however, neither that by the melting of ice, nor that by evaporation of water, nor indeed anything founded on the doctrine of latent heat at all. It has been founded on the elevation of temperature produced in water by the communication to it of the heat to be measured; and, for the sake of distinction from calorimetry by latent heat or otherwise, it may be called thermometric calorimetry. We can only consider it now in anticipation, as we have not yet reached the foundation of any thermometric scale; but even now we can see that, if in any way we fix upon any two particular determinate temperatures, the quantity of water warmed from the lower to the higher of them by the heat to be measured is a perfectly definite measure for the quantity of this heat. The two temperatures chosen for thermometric calorimetry are those marked 0° and 1° on the centigrade scale. The first of these we can understand at present, being the temperature at which ice melts under ordinary atmospheric pressure. The second is fully defined in §§ 35, 37, 51, 67. The quantity of heat required to raise unit mass of water (1 kilogramme, or 1 gramme, or 1 milligramme, or 1 lb, as the case may be) from zero to 1° C. is called the thermal unit centigrade, and sometimes, especially by French writers, the "calerie."

§ 7. *Comparison of Calorimetric Units.*—Observations by Provostaye and Desains, and by Regnault, on the latent heat of fusion of ice, show it to be 79·25 thermal units centigrade, a result differing but little from Black's original determination, which made it 142 thermal units Fahr.,—this being equal to 78·9 thermal units centigrade. Thus if one kilogramme of ice be put into 79½ kilogrammes of water at 1° C., and left till the whole is melted (the process may be accelerated by not too violent stirring, § 9), the result will be 80½ kilogrammes of water at 0° C.

Regnault's experiments on the latent heat of steam show that the quantity of heat required to convert into steam unit

³ This is chosen because all the most accurate experimental determinations depending on a conventional standard for atmospheric pressure, such as measurements of thermal expansions and specific heats of gases, of latent heat of melting solids in terms of a calorimetric unit depending on the centigrade thermometric scale, of latent heats of vapours, and thermal expansions of mercury and glass, and comparisons of mercury and air thermometers, are those of Regnault, and were made in Paris and calculated and given to the world according to an arbitrary standard atmosphere corresponding to 76 centimetres of mercury there.

¹ The instrument itself is preserved in the *Conservatoire des Arts et Métiers* in Paris. It is described and explained in Maxwell's *Theory of Heat*, chap. iii.

² *Pogg. Ann.*, Sept. 1870, and *Phil. Mag.*, 371; Maxwell's *Theory of Heat*, p. 61.

mass of water at the boiling temperature, under standard atmospheric pressure (§ 5), is $536\frac{1}{2}$ thermal units centigrade. This number, which is no doubt very accurate, differs but little from Watt's final result, 960 thermal units Fahr. (equal to 533.3 thermal units centigrade), obtained by him, in a repetition in 1781 of experiments which he had commenced in 1765 at the invitation of Black, whose pupil he was.

§ 8. *Preliminary regarding the Nature of Heat.*—*Dynamical Calorimetry.*—From the dawn of science till the close of last century two rival hypotheses had been entertained regarding the nature of heat, each with more or less of plausibility, but neither on any sure experimental basis:—one that heat consisted of a subtle elastic fluid permeating through the pores or interstices among the particles of matter, like water in a sponge; the other that it was an intestine commotion among the particles or molecules of matter. In the year 1799 Davy, in his first published work entitled *An Essay on Heat, Light, and Combinations of Light*,¹ conclusively overthrew the former of these hypotheses, and gave good reason for accepting as true the latter, by his celebrated experiment of converting ice into water by rubbing two pieces of ice together, without communicating any heat from surrounding matter. A few years earlier Rumford had been led to the same conclusion, and had given very convincing evidence of it in his observation of the great amount of heat produced in the process of boring cannon in the military arsenal at Munich, and the experimental investigation on the excitation of heat by friction² with which he followed up that observation. He had not, however, given a perfect logical demonstration of his conclusion, nor even quite a complete experimental basis on which it could be established with absolute certainty. According to the materialistic doctrine it would have been held that the heat excited by the friction was not *generated*,³ but was *produced*, squeezed out, or let flow out like honey from a broken honeycomb, from those parts of the solid which were cut or broken into small fragments, or rubbed to powder in the frictional process. If this were true, the very small fragments or powder would contain much less heat in them than an equal mass of continuous solid of the same substance as theirs. But unhappily the caloristic doctrine, besides its fundamental hypothesis, which we now know to be wrong, had given an absurd and illogical test for quantity of heat in a body, of which a not altogether innocuous influence still survives in our modern name “specific heat”; and Rumford actually, in trying to disprove the materialistic doctrine, was baffled by this sophism. That is to say, he measured the specific heat or “capacity for heat” of the powder, and he found that the powder took as much heat to warm it to a certain degree as did an equal mass of the continuous solid, and from this he concluded that the powder did not contain less heat than the continuous solid at the same temperature. This conclusion is so obviously unwarranted by the premises that it is difficult to imagine how Rumford could have for a moment put forward the “capacity for heat” experiment as proving it, or could have rested in the conclusion without a real proof, or at least the suggestion of a real proof. All that Rumford's *argument* proved was that the fundamental hypothesis of the “calorists” and their other altogether gratuitous doctrine of equality of “specific heat” as a test for equality of whole quantities of heat in matter could not be both true; and any one not inclined to give up the

materialistic hypothesis might have cheerfully abandoned the minor doctrine, and remained unmoved by Rumford's argument. If Rumford had but melted a quantity of the powder (or dissolved it in an acid), and compared the heat which it took with that taken by an equal weight of the continuous solid, he would have had no difficulty in proving that the enormous quantity of heat which he had found to be excited by the friction had not been squeezed, or rubbed, or pounded, out of the solid matter, but was really brought into existence, and therefore could not be a material substance. He might even, without experiment, have pointed out that, if the materialistic doctrine were true, it would follow that sufficiently long-continued pounding of any solid substance by pestle and mortar, whether by hand or by aid of machinery, would convert it into a marvellous powder possessing one or other of two properties about equally marvellous. Either the smallest quantity of it thrown into an acid would constitute a freezing mixture of unlimited intensity,—the longer it had been pounded, the more intense would be its frigorific effect on being dissolved,—or the powder would be incapable of being warmed by friction, because it had already parted with all the heat which friction could rub out of it. The real effect of Rumford's argument seems to have been to save the intellectual consciences of those who were not inclined to give up the materialistic doctrine, and to save them from the trouble of reading through Rumford's paper and thinking for themselves, by which they would have seen that his philosophy was better than his logic, and would inevitably have been forced to agree with him in his conclusion. It is remarkable that Davy's logic, too, was at fault, and on just the same point as Rumford's, but with even more transparently logical fallaciousness, because his argument is put in a more definitely logical form.

“Let heat be considered as matter, and let it be granted that the temperature of bodies cannot be increased unless their capacities are diminished from some cause, or heat added to them from some bodies in contact”!!

* * * * *

“*Experiment II.*—I procured two parallelepipeds of ice,⁴ of the temperature of 29°, 6 inches long, 2 wide, and $\frac{3}{4}$ of an inch thick; they were fastened by wires to two bars of iron. By a peculiar mechanism their surfaces were placed in contact and kept in a continued and violent friction for some minutes. They were almost entirely converted into water, which water was collected and its temperature ascertained to be 35° after remaining in an atmosphere of a lower temperature for some minutes. The fusion took place only at the plane of contact of the two pieces of ice, and no bodies were in friction but ice. From this experiment it is evident that ice by friction is converted into water, and, according to the supposition, its capacity is diminished; but it is a well-known fact that the capacity of water for heat is much greater than that of ice, and ice must have an absolute quantity of heat added to it before it can be converted into water. Friction consequently does not diminish the capacities of bodies for heat.”—Davy's *Essay on Heat, Light, and Combinations of Light*, pp. 10–12.

[Delete from “and, according to the supposition,” to “greater than that of ice” inclusive; and delete the lame and impotent conclusion stated in the last eleven words. The residue constitutes an unanswerable demonstration of Davy's negative proposition that heat is not matter.]

§ 9. *Joule's Dynamical Equivalent of Heat.*—It is remarkable that, while Davy's experiment alone sufficed to overthrow the hypothesis that heat is matter, and Rumford's, with the addition of just a little consideration of its relations to possibilities or probabilities of inevitable alternatives, did the same, fifty years passed before the scientific world became converted to their conclusion,—a remarkable instance of the tremendous efficiency of bad logic in confounding public opinion and obstructing true philosophic thought.

⁴ “The result of the experiment is the same if wax, tallow, resin, or any substance fusible at a low temperature be used; even iron may be fused by collision, as is evident by the first experiment.”

¹ Published in 1799 in *Contributions to Physical and Medical Knowledge, principally from the West of England*, collected by Thomas Beddoes, M.D., and republished in Dr Davy's edition of his brother's collected works, vol. II., London, 1836.

³ Compare quotation from Cavendish, footnote, § 2 above.

Joule's great experiments from 1840 to 1849,¹ creating new provinces of science in the thermodynamics of electricity, and magnetism, and electro-chemistry, recalled attention to Davy and Rumford's doctrine regarding the nature of heat, and supplied several fresh proofs, each like Davy's absolutely in itself complete and cogent, that heat is not a material substance, and each advancing with exact dynamical measurement on the way pointed out by Rumford in his measurement of the quantity of heat generated in a certain time by the action of two horses not urged to overwork themselves. The full conversion of the scientific world to the kinetic theory of heat took place about the middle of this century, and was no doubt an immediate consequence of Joule's work, although Rumford and Davy's demonstrative experiments, and the ingenious and penetrating speculations of Mohr, and Séguin, and Mayer, and the experimental thermodynamic measurements of Colding, all no doubt contributed to the result. Each of the several subjects of thermodynamic measurement undertaken by Joule gave him a means of estimating the quantity of work required to generate a certain quantity of heat; but after several years of trials he was led to prefer to all others the direct method of simply stirring a quantity of water by a paddle, and measuring the quantity of heat produced by a measured quantity of work; and this method he has accordingly used in all his experiments for the purpose of determining the "dynamical equivalent of heat" from the year 1845 to the present time. By this he found his final result of 1849,² which was 772 Manchester foot-pounds for the quantity of work required to warm by 1° Fahr., at any temperature between 55° and 61° Fahr., 1 lb of water weighed in vacuum. In 1870 he commenced work for a fresh determination of the dynamical equivalent of heat at the request of the British Association, and the result was communicated to the Royal Society³ about the end of 1877, with the following preface:—

"The committee of the British Association on standards of electrical resistance having judged it desirable that a fresh determination of the mechanical equivalent of heat should be made by observing the thermal effects due to the transmission of electrical currents

³ "New Determination of the Mechanical Equivalent of Heat," by James Prescott Joule, *Phil. Trans.* for 1878, pp. 365-383.

through resistances measured by the unit they had issued, I undertook experiments with that view, resulting in a larger figure (782·5, *Brit. Assoc. Report*, Dundee, 1867, p. 522) than that which I had obtained by the friction of fluids (772·6, *Phil. Trans.*, 1850, p. 82).

"The only way to account for this discrepancy was to admit the existence of error either in my thermal experiments or in the unit of resistance. A committee, consisting of Sir William Thomson, Professor P. G. Tait, Professor Clerk Maxwell, Professor B. Stewart, and myself, were appointed at the meeting of the British Association in 1870; and with the funds thus placed at my disposal I was charged with the present investigation, for the purpose of giving greater accuracy to the results of the direct method."

The result of this final investigation of Joule's is 772·43 Manchester foot-pounds for the quantity of heat required to warm from 60° to 61° Fahr. a pound of water weighed in vacuum, which is about $\frac{1}{50}$ th per cent. greater than the final result of 1849 expressed in the same terms. According to Regnault's measurements⁴ of the thermal capacity of water at different temperatures from 0° to 230° C., it must be about '08 per cent. greater at 60° Fahr. than at 32°. According to this, Joule's thermodynamic result would be 771·81 Manchester foot-pounds, for the work required to warm a pound of water from 32° to 33° Fahr., or 1389·26 to warm a pound of water from 0° to 1° C. Reducing 1389·26 feet to metres, we have 423·437 metres. At Paris the force of gravity is about $\frac{1}{100}$ th per cent. less than in Manchester. Hence for about the middle of France and the southern latitudes of Germany, Joule's result, according to the ordinary reckoning of French and German engineers, may be stated as 423·5 kilogramme-metres for the amount of work required to warm 1 kilogramme of water from 0° to 1° C. The force of gravity at Manchester is 981·34 dynes (centimetres per second per second). Multiplying 423·437 by this, we find accordingly 41,553,000 centimetre-dynes, or "ergs," for the amount of work in C.G.S. measure required to warm 1 gramme of water from 0° to 1° C.

THERMOMETRY.

§ 10. *Preliminary for Thermometry.*—*Sense of Heat (resumed from § 1).*—The sense of heat and cold is not simply dependent on the temperature of the body touched. If a person takes a piece of iron, or a stone, or a piece of wood, or a ball of worsted, or a quantity of finely carded cotton-wool, or of eider down, in his hand, or touches an iron column, or a stone wall, or a wooden beam, or a mass of wool or of down, he will perceive the iron cold, the stone cold, but less cold than the iron, the wood but slightly cold—much less cold than the stone, the wool or down decidedly warm.

We now know that if all the bodies before being touched were near one another in similar exposure, they must have been at the same temperature, and from the iron and stone being felt cold we know that this mean temperature is lower than the temperature of the hand. Each of the bodies touched must at the first instant have taken some heat from the hand, and therefore, if the perception were quick enough, all at the very instant of being touched would have seemed cold to the sense. The iron by its high thermal conductivity (§§ 76, 78, 80) keeps drawing off heat from the hand and lowering its temperature, till after many seconds of time an approximately permanent temperature is reached, which may be considerably lower than the temperature of the hand before contact, but somewhat higher than the previous temperature of the iron, because of the internal furnace (see THERMODYNAMICS) generating heat in the hand. A similar result, but in less time and with less ultimate lowering of temperature of the hand, takes place when stone is touched. When wood is touched its comparatively small conductivity (§ 76) allows its surface to be warmed again after the first few seconds, sometimes to a higher tem-

⁴ *Relation des Expériences*, vol. i. p. 748, Paris, 1847.

perature than that of the hand before contact; and thus, if the sensation could be perfectly remembered, it would be perceived that the wood was first felt to be cold, and afterwards to be warm. This latter warmth is rendered very perceptible by first holding the hand in contact with a piece of wood, as for instance a mahogany table, for a considerable time, half a minute or more, and then suddenly removing it; a sense of cold is immediately perceived in consequence of the exposure of the hand to the air. The foot is similarly sensitive. If, after holding a bare foot for some time in the air, it be placed on a varnished wooden floor, the floor is perceived to be cold, and if, after standing some time with it pressed to the floor, the foot be suddenly lifted, the air now seems cold by contrast. If a person walks with bare feet on a wooden floor, a continued sense of cold is experienced; and if, immediately after doing so, he sits down, and holds his feet in the air, the air seems to be warm by contrast. The same sensations are perceived even on a carpeted floor, but much less markedly than on a plain wooden floor, and much less markedly on a plain wooden floor than on a varnished wooden floor, and much less markedly on a varnished wooden floor than on a stone floor. In the case of touching soft wool, or finely carded cotton-wool, or eider down, the first instantaneous sensation of cold is scarcely if at all perceived, and that which first provokes consciousness is the subsequent heating; and it is very startling to find a body which we know to be ice-cold on a frosty day feeling positively warm to the first consciously perceptible sensation after it is touched. In this case the small thermal conductivity or great thermal resistance of the substance is such that heat is carried off by it from the hand slower than it was carried off by radiation and aerial convection (§§ 70, 71) before contact; and thus, after the first momentary cooling of the hand by the initial cataract of heat from it to the cold body touched, in a small fraction of a second of time a higher temperature is attained by the hand than it had before contact.

§ 11. *Sense of Temperature.*—The sense of heat is in reality a somewhat delicate thermal test when properly used. Even an unskilled hand alternately dipped into two basins of water will, as we have found by experiment, detect a difference of temperature of less than a quarter of a degree centigrade; and there can be no doubt that bath and hospital attendants, and persons occupied with hot liquors in various manufactures, such as dyeing, can detect much smaller differences of temperature than that, and, what is still more remarkable, can remember permanently sensations of absolute temperature sufficiently to tell within less than a degree centigrade that the temperature of a bath, or a poultice, or dyeing liquor is "blood heat," or "fever heat," or some other definite temperature to which they have been accustomed.

§ 12. *Thermometry by Sense of Heat—with arbitrary Centigrade Scale deduced from Mixtures of Hot and Cold Water.*—Without knowing anything of the nature of heat we might find a complete system of thermometry on the mixing of hot and cold water with no other thermoscope (§ 13) than our sense of heat, if we had but two definite constant temperatures of reference. These in practical thermometry are supplied by the melting-point of ice and the temperature of steam from water boiling in air at a definite pressure (the "atmo" or standard atmosphere, § 5). Thus, suppose perfectly abundant supplies of iced water and of water at the boiling temperature to be available, and suppose it to be desired to measure the temperature of a river, or lake, or sea. Take measured quantities of the boiling and of the ice-cold water, and mix them by trial until, tested by the hand, the mixture is found to have the same temperature as that of the mass of water of which the temperature is to be determined. Suppose, for example, the mixture giving the required temperature to consist of 86·6 parts by weight

of ice-cold water, and 13·4 parts by weight of boiling water; the required temperature is 13·4 on a perfectly definite scale of thermometry in which the temperature of ice-cold water is called zero, that of boiling water 100, and other temperatures are reckoned according to the law of proportion of mixtures of water in the manner indicated by the example, and defined generally in § 31 below. For temperatures within the range of sensibility of the hand this method would give more accurate results than many common thermometers sold by instrument makers for ordinary popular purposes. It may be relied upon for absolute accuracy within $\frac{1}{10}$ th of a degree centigrade, provided the mixing of hot and cold water is performed with sufficiently large quantities of water, and with all proper precautions to obtain in that part of the process all the accuracy obtainable by the living thermoscope.

We shall see (§ 25) that with the most accurate mercury or air thermometers, made for scientific investigation and carefully tested, absolute determinations can scarcely be depended upon within $\frac{1}{10}$ th of a degree centigrade. The method of mixtures with only the sensory thermoscope is not limited to the range of temperature directly perceptible with unimpaired sensibility; but when the temperature to be tested is beyond this range an indirect method must be followed, as thus:—

A large quantity of water too warm for the hand is to be tested. Mix it with say twice its weight of ice-cold water, this giving a convenient temperature for the hand; then find by trial what proportions of ice-cold and boiling water give a mixture of the same temperature as tested by the hand; suppose these proportions to be 26·2 of boiling water and 73·8 of ice-cold water. The temperature of the mixture is by definition 26·2, and on the same principle the required temperature is three times this, or 78·6.

This system of thermometry is, however, strictly limited to the range between the freezing and boiling points of water, for we do not at present consider the possibility (see LIQUID; STEAM; MATTER, PROPERTIES OF; THERMODYNAMICS) of obtaining and using thermometrically quantities of water below the freezing point and above the boiling point. It is described here, not only because it is very instructive in respect to the principles of thermometry, but because it is in point of fact the thermometric method used through a large range of processes not only in the arts but in scientific investigation. In many cases the hand is a more convenient and easy test than a common mercury thermometer, and it has just about the same sensibility, the commonest thermometers in popular use being in fact scarcely to be read to a quarter of a degree centigrade. In respect to accuracy a common cheap thermometer, though perhaps a degree or two wrong in its absolute indications, may still be used as an accurate indicator of equality of temperatures just as is the hand in the method of mixtures.

In many cases the hand is more convenient than the thermometer, in other cases the thermometer is more convenient than the hand, but in many cases the thermometer is applicable when the hand is not. When the quantities of water tested are abundant, the hand is always the quicker test, but there must be abundance of water to allow it to be satisfactorily and accurately applicable.

THERMOSCOPES DIFFERENTIAL AND INTRINSIC.

Differential Thermoscopes essentially continuous.—*Intrinsic Thermoscopes discontinuous and continuous.*—*Single and Multiple Intrinsic Thermoscopes (discontinuous).*—*Continuous Intrinsic Thermoscopes.*

§ 13. A thermoscope is an indicator of temperature. A differential thermoscope is a thermoscope which shows difference, or tests equality, of simultaneous temperatures in two places. Its action is essentially continuous, de-

pending on difference of temperature between the two places, and showing zero continuously when the temperatures of the two places are varied, provided they are kept exactly equal. Every kind of differential thermoscope, and of continuous intrinsic thermoscope, must be founded on some property of matter, continuously varying with the temperature, as density of a fluid under constant pressure, pressure of a fluid in constant volume, volume of the liquid part of a whole mass of liquid and solid kept in constant volume,¹ steam-pressure of a solid or liquid,² shape or density of an elastic solid under constant stress, stress of an elastic solid in a constant state of strain, viscosity of a fluid, electric current in a circuit of two metals with their junctions at unequal temperatures, electric resistance of a conductor, magnetic moment of a steel or loadstone magnet.

Examples:—(1) Leslie's differential air thermometer; (2) steam-pressure differential thermometers (§§ 39–44 below); (3) Joule's hydraulic and pneumatic differential thermoscopes (*Memoirs Chem. Soc.*, vol. iii. p. 201; *Proc. Lit. and Phil. Soc. Manchester*, vol. iii. p. 73; *Ibid.*, vol. vii. p. 35); (4) viscosity differential thermoscope (*Proceedings R.S.E.*, April 5, 1880); (5) thermo-electric differential thermometer; (6) Siemens electric resistance differential thermometer; (7) thermo-magnetic differential thermometer (see *Proceedings R.S.E.* for April 5, 1880).

§ 14. *Intrinsic Thermoscopes.*—An intrinsic thermoscope is an instrument capable of indicating one definite temperature or several definite temperatures, or all temperatures within the range of the instrument, whatever it may be—the temperature or temperatures indicated being intrinsically determined by the constitution of the instrument and indicated by some recognizable feature of the instrument which changes discontinuously or continuously, as the case may be, and which is always the same when the instrument is brought back again and again to the same temperature, whatever changes it may have experienced in the intervals. Discontinuous intrinsic thermoscopes show only a limited number of temperatures. A continuous intrinsic thermoscope shows any temperature whatever throughout the range of efficiency of the instrument, ideally any temperature whatever, though in practice every thermoscope is limited, some with both inferior and superior limit, as the mercury thermometer by the freezing of mercury at about -39° C., and the bursting pressure of mercury-steam a little above $+360^{\circ}$ C.; others with only a superior limit, as metallic thermoscopes, whether thermo-elastic, or thermo-electric, or electric-resistance, or thermo-magnetic, by the melting of their substances at very high temperatures, or, in the case of the thermo-magnetic instrument, by the total or partial loss of its magnetism at some temperature much below the melting point of its substance. A continuous intrinsic thermoscope, when applied to a body whose temperature is changing, shows continuously every variation of temperature within its range of efficiency.

§ 15. *Discontinuous Intrinsic Thermoscopes.*—A single intrinsic thermoscope is a thermoscope which shows whether the temperature of the body to which it is applied is higher or lower than some one definite temperature depending on intrinsic quality of the instrument.

Examples:—(1) a piece of ice, or of wax, or of fusible metal; (2) an apparatus for boiling water or other liquid under a perfectly constant pressure; (3) an apparatus for boiling water under the natural atmospheric pressure, and a barometer to measure exactly what the pressure is at the time.

A multiple intrinsic thermoscope might be made by preparing a graduated series of metallic alloys, numbering them in order of their melting points, and arranging them together-conveniently for use. The temperature might be reckoned numerically, according to the number of the alloys that melt, when the whole series is exposed to the temperature to be tested. This discontinuous numerical reckoning of temperature is perfectly analogous to the Birmingham

reckoning of wires and sheet metals by numbered gauges. Ideally it may be made infinitely nearly continuous by making a series of alloys with fine enough gradation of composition, but the method is in its essence discontinuous. It is useful for many special applications in science and in the arts, as for instance in that very fundamental one (§ 12) of giving one of the fixed points in the ordinary thermometric scale, the "freezing point"; also in a form of safety valve for boilers or hot-water pipes, in which a plug fixed by solder is released by the melting of the solder when the temperature reaches a certain limit; also an exceedingly useful guard against overheating in the flue of a stove, by which a stopper is allowed to fall by the melting of a leaden support, and stop the draught, before the temperature reaches the highest limit judged permissible.

§ 16. *Continuous Intrinsic Thermoscopes.*—Continuity of indication requires, as said above (§ 13), choice of some property or properties of matter varying continuously with temperature, such as those enumerated in § 13. A continuous intrinsic thermoscope must have a feature, depending on the chosen property of matter, which shall vary with perfect continuity when the temperature is gradually changed, and shall always be the same when the instrument is brought to the same temperature again and again, whatever variation of temperature it may have experienced in the intervals. The accuracy of an intrinsic thermometer, whether discontinuous or continuous, depends upon permanence of quality of the material and of the mechanical constitution of the instrument, according to which the recognized feature shall always be very accurately the same for the same temperature. The sensibility or delicacy of a continuous intrinsic thermometer depends upon the recognizability of change in its indicating feature with very small change of temperature.

§ 17. The property of matter chosen as the foundation of almost all ordinary continuous intrinsic thermoscopes in common use is interdependence of the density, the temperature, and the pressure of a fluid. The only other thermoscopes which can be said to be in common use at all are "metallic thermometers" (see THERMOMETER; MATTER, PROPERTIES OF); these depend upon the change of shape of a rigid elastic solid under a stated stress, or on the change of shape of a compound solid, composed of two elastic solids of different substances melted or soldered together. For the present we confine our attention to the former and much larger class of instruments. The general type of all those instruments, except the steam-pressure thermometer (§§ 39–46 below), is a glass measure, measuring the bulk of a fluid. To give the requisite practical sensibility to the measurement, the glass, except for the case, of the constant-pressure gas thermometer (§§ 64–67 below) and of the steam-pressure thermometer is made of a shape which may be generally described as a bottle with a long narrow neck. The body of the bottle, which may either be spherical or of an elongated form, is called the bulb, and the neck is called the tube or stem (stem we shall most frequently call it, to obviate ambiguities without circumlocutions). The thermometric fluid may be all liquid, as mercury, or oil, or alcohol, or ether, or glycerine and water; or it may be all gas, as common air, or hydrogen, or carbonic acid; or it may be partly liquid and partly steam (steam being a name which we shall invariably use to designate the less dense portion of a fluid substance at one temperature and pressure throughout, and in equilibrium, with two parts of different densities). This last case is different from the two preceding, in respect to the character of the thermometric indication: the whole volume of the thermometric substance may be changed from that of all liquid to that of all steam without changing the temperature or the pressure, and the pressure cannot be changed without changing the

¹ This is the principle of the ordinary mercury or spirit thermometer.

² For definition of steam see § 17 below.

temperature, provided the substance is kept in the double condition of part liquid and part steam; in other words, in this case the pressure depends upon the temperature alone and is independent of the volume. In the steam-pressure thermometer, therefore, there is no delicate measuring of volume of the thermometric substance, and the vessel containing it is not in the shape of bulb and stem; but the instrument consists essentially of a means of measuring the pressure of the thermometric substance, with a test that it is really in the twofold condition of part liquid and part steam, whether by seeing it through a glass containing-vessel, or by a proper hydraulic appliance for ascertaining that the pressure is not altered by rarefaction or condensation when the temperature is kept constant. Realized thermometers of this species, quite convenient for many practical purposes, with steam of sulphurous acid, of water, and of mercury, to serve for different ranges of temperature, from below -30° C. to above $+520^{\circ}$ C., are described in §§ 39-44 below.

§ 18. In respect to general convenience for large varieties of uses, whether for scientific investigation, or for the arts, or for ordinary life, liquid thermometers are generally and with good reason preferred; but the general preference of either mercury or spirits of wine for the liquid, which is so much the rule, is not (§ 20 below) so clearly reasonable. For ordinary uses in which the thermometer has to be moved about and placed in various positions, gas thermometers are much less convenient, because they require essentially an accurate measurement of pressure, and generally for this purpose a column of liquid. But when the thermometer is to be kept always in one position, as for instance when it is devoted to testing the temperature of the air indoors or out of doors, Amontón's air or gas thermometer is really as convenient and as easily read as any liquid thermometer can be: but even it, simple as it is, involves a triple division of the hermetically sealed space, with three different conditions of occupation, —one part occupied by the thermometric substance, another by the pressure-measuring vapourless liquid,¹ and the third vacuum: and it is by so much the less simple than the liquid thermometer that in the liquid thermometer the enclosed space is divided into only two parts, one occupied by the thermometric liquid, and the other by its steam, with

Fig. 2.

¹ An instrument closely resembling that shown in the drawing (fig. 2), but with common air instead of hydrogen, was made for the writer of this article, by Casella, about fifteen years ago, and has been used for illustrations in the natural philosophy class in Glasgow university ever since. It is probably an exceedingly accurate air thermometer. When it was set up in the new lecture-room after the migration to its present locality in 1870, the tube above the manometric liquid column was cleared of air. To do this the instrument must be held in such a sloping position, with the closed end of the tube down, as to allow the bubble of air always found in it to rise and burst in the bulb. If now the instrument is placed in its upright position, the liquid refuses to leave the top of the tube, and it would remain filling the tube (probably, for ever) if left in that position. No violence of knocking which has been ventured to try to bring it down has succeeded. To bring it down a bubble of air must be introduced. The bubble must be very small, so that the pressure of the air which fills it may become insensible when this air expands into the space of the tube left above the manometric column after it descends to its proper thermoscopic position. Special experiments made for this article in September 1879 showed

or without some admixture of common air. For accuracy the air or gas thermometer is superior, we might almost say incomparably superior, to the mercury thermometer, and, though in a much less degree, still decidedly superior to even the most accurate liquid thermometer, on account of the imperfect constancy of the glass containing-vessel.

§ 19. If we were quite sure of the bulk measurement given by the glass bulb and tube, liquid thermometers would be quite as accurate as gas thermometers. For there is no difficulty in giving any required degree of sensibility to the instrument by making the bulb large enough; and the quality of the liquid itself, hermetically sealed in glass, may be regarded as being as constant as anything we know of in the material world. But, alas for thermometry, the glass measure is not constant! In fact, glass is a substance of very imperfect elasticity (ELASTICITY, § 4, vol. vii. p. 797); and it is found that the bulb of a thermometer is not always of the same volume at the same temperature, but that, on the contrary, it experiences uncertain changes exceedingly embarrassing in thermometry. In the course of a few months after a thermometer is filled and sealed, the bulb generally shrinks by some uncertain amount of from $\frac{1}{10000}$ to $\frac{1}{20000}$ of its bulk, sometimes even in the course of years to almost $\frac{1}{10000}$. This has been discovered by a gradual rising of the freezing point, in new mercury thermometers, generally as much as from $\frac{1}{4}^{\circ}$ to $\frac{1}{2}^{\circ}$ C., sometimes to as much as 1° , which corresponds to a shrinkage of $\frac{1}{10000}$, as the bulk-expansion of mercury is when its temperature is raised from 0° to 100° C. (Table II. below) $\frac{1}{81.1}$, or $\cdot 01815$, of its bulk at 0° . After a few months or a few years this progressive shrinkage ceases to be sensible; but if the thermometer at any time is exposed to the temperature of boiling water or any higher temperature, an abrupt sub-permanent enlargement of the bulb is produced, and the freezing point, if tested for by placing the thermometer in ice and water, is found to be lowered; then again for weeks or months or years there is a gradual shrinkage, as shown by a gradual rising of the freezing point when the thermometer is tested again and again by placing it in ice and water. A very delicate mercury thermometer, which has been kept for years at ordinary atmospheric pressures when out of use, and never when in experimental use exposed to any temperature higher than about 30° C., or much lower than the freezing point, becomes very constant, and probably may never show any change of as much as $\frac{1}{10}$ of a degree C. in its freezing point or in its indication at any other absolutely definite temperature, within some such range as from -20° or -10° C. to $+30^{\circ}$ or $+40^{\circ}$ C. But the abrupt and irregular changes, produced by exposing the thermometer to temperatures much above or much below some such limited range as that, constitute a very serious difficulty in the way of accurate thermometry by the mercury-in-glass thermometer.

that in the nine years during which the instrument had remained undisturbed in the lecture-room a very sensible quantity of air (enough to render the temperature indication about 35° C. too low) had leaked from the bulb through the sulphuric acid into the tube above the liquid column. This air was eliminated, and the instrument reset up for use, an operation completed in a minute at any time if need be. Some careful experiments were then made by Mr Macfarlane to ascertain if the pressure of vapour or gas from the sulphuric acid, in the tube, was sensible, with a happily decisive result in the negative. The bulb was kept at a very constant temperature by cold water; the uppermost few centimetres of the liquid column, and the whole of the tube above it, were heated to about 100° C. by steam blown through a glass jacket-tube, fitted round it for the purpose. The height of the manometric column remained sensibly unchanged! Further experiments must be made to ascertain whether or not there is enough of variation of absorption of the air by the sulphuric acid with variation of temperature, and enough of the consequent variation of pressure in the bulb, to vitiate sensibly the thermometric use of the instrument. If, as seems improbable, the answer to this question be unhappily affirmative, a satisfactory negative might be found by substituting hydrogen for common air.

Although the greatest care has been bestowed by Regnault, Joule, and all other accurate thermometric experimenters to avoid error from this cause, we have still but little definite information as to its natural history in thermometers of different qualities of glass, different shapes of bulb, and constructed differently in respect to processes of glass-blowing, boiling the mercury, and sealing the stem. We do not even know whether the excess of the atmospheric pressure outside the bulb over the pressure due to mercury and Torricellian vacuum inside is influential sensibly, or to any considerable degree, in producing the gradual initial shrinkage. If it were so we might expect that the effect of heating the thermometer up to 100° or more at any time would be rather to produce an accelerated shrinkage for the time than what it is found to be, which is a return towards the original larger volume, followed by gradual shrinkage from day to day and week to week afterwards. A careful comparison between two thermometers constructed similarly in all respects, except sealing one of them with Torricellian vacuum and the other with air above the mercury, would be an important contribution to knowledge of this subject, interesting, not only in respect to thermometry, but also to that very fundamental question of physical science, the imperfect elasticity of solids (see ELASTICITY, § 4).

§ 20. The error of a thermometer due to irregular shrinkages and enlargements of the bulb is clearly the less the greater is the expansion of the thermometric fluid with the given change of temperature. By the investigation of § 30 we can calculate exactly how much the error is for any stated amount of abnormal change of bulk in the bulb. But it is enough at present to remark that for different liquids in the same or in similar bulbs the errors are very nearly in the inverse proportions of the expansions of the liquids. Now (Table III. below) in being warmed from 0° to 1° C. alcohol expands 6 times as much as mercury, methyl butyrate 7 times, and sulphuric ether 8½ times. Hence if irregular changes of bulk of the bulb leave, as they probably do in practice, an uncertainty of $\frac{2}{10}$ ths of a degree in respect to absolute temperature by the best possible mercury-in-glass thermometers used freely at all temperatures from the lowest up to 100° C., the uncertainty from this cause will be reduced to $\frac{1}{3}$ th of a degree by using alcohol, or $\frac{1}{5}$ th by using methyl butyrate instead of mercury; it may therefore, in a glass thermometer of alcohol or of the butyrate, be considered as practically annulled (§ 19) after a few weeks or months have passed, and the first main shrinkage is over.

§ 21. An alcohol-in-glass thermometer is easily made strong enough to bear a temperature of 100° C., as this gives by the pressure of the vapour an internal bursting pressure of not quite an atmosphere and a quarter in excess of the atmospheric pressure outside. The boiling point of methyl butyrate (Table III. below) is 102° C.; a thermometer of it may therefore be used for temperatures considerably above 100° C., but how much above we cannot tell, as we have not experiments as yet on the pressure of its vapour at temperatures above its boiling point. The pressure of vapour of sulphuric ether (Table VI. below) is too great to allow a thermometer of this liquid sealed in glass to be used much above 60° or 70° C., but for low temperatures it makes a very valuable thermometer. It was used in 1850 by W. Thomson in finding by experiment the lowering of the freezing point of water, predicted theoretically (see THERMODYNAMICS) by J. Thomson in 1849 (*Trans. R. S. E.*), and gave a sensibility of 128 divisions to 1° C. Glass thermometers with ether, or chloroform (whose expansion is about 4 per cent. greater than that of ether), were used by Joule and W. Thomson in experiments¹ on changes of temperature experienced by

bodies moving through air, in one of which the sensibility was as great as 330 scale divisions to the 1° C. All these liquids and many others in the modern chemist's repertory of oils and ethers and alcohols, besides the superior sensibility which they give by their greater expansions, have a great advantage over mercury for some thermometric purposes in their smaller specific gravity. This allows the bulb to be larger, with less liability to break or to give disturbed readings through distortion by the weight of the contained liquid.

§ 22. Liquids which wet the glass have another great advantage over mercury in their smaller capillary attraction (see CAPILLARY ACTION, vol. v. p. 56; and MATTER, PROPERTIES OF) and in the constancy of their 180° angle of contact with the glass, instead of the much greater absolute intensity of capillary attraction in the mercury, and its very variable angle of contact, averaging about 45° when the mercury is rising, and about as much as 90° when it is falling. On account of these variations the bulb of the mercury thermometer is subjected to abrupt variations of pressure when the mercury is rising or falling. The greatest and least pressures due to this cause are experienced when the angle of contact is respectively least and greatest, and differ by the pressure due to a vertical column of mercury equal in height to the difference of depressions of mercury in a capillary tube of the same bore as the thermometer stem when the angle of contact is changing from one to the other of the supposed extreme values. Hence the mercury in a thermometer rises and falls by jerks very noticeable in a delicate thermometer when looked at with a lens of moderate magnifying power, or even with the naked eye. Dr Joule informs us that this defect is much greater in some thermometers than in others, and that he believes it is greatly owing to the tube being left unsealed for too long a time after the introduction of the mercury (by which it is to be presumed something of a film of oxide of mercury is left on the glass to reappear on the surface of the mercury when it sinks as it cools after the sealing of the end). In Joule's own thermometers not the smallest indication has ever been detected of what he calls "this untoward phenomenon, which is calculated to drive an observer mad, if he discovers it towards the close of a series of careful experiments." Their admirable quality in this respect is no doubt due to the great care taken by the maker, Mr Dancer, under Joule's own instructions, to have the mercury and the interior of the bulb and tube thoroughly clean, and to guard it from exposure to any "matter in its wrong place" until completion of the sealing. But no amount of care could possibly produce a mercury thermometer of moderate dimensions moving otherwise than by jerks of ever so many divisions, if its stem were of fine enough bore to give anything approaching to two or three hundred divisions to the centigrade degree.

§ 23. One chief objection to the use of alcohol or other volatile liquid for the thermometric substance in ordinary glass thermometers is the liability to distillation of some of the liquid into the stem and head reservoir, unless the glass above the level of the liquid be kept at least as warm as the liquid. On this account a spirit thermometer is not suitable for being plunged into a space warmer than the surrounding atmosphere with the stem simply left to take the temperature to which it comes in the circumstances. But whether for elaborate experimental use, or for the most ordinary thermometric purposes, there is little difficulty in arranging to keep the part of the stem which is above the liquid surface somewhat warmer than at the liquid surface, and this suffices absolutely to prevent the evil of distillation. The only other objection of any grave validity²

² There is one other objection which, though often stated as very grave against the thermometric use of any other liquid than mercury, we do not admit to be so. It is that when the temperature is rapidly sink-

¹ *Phil. Trans.* for 1860, p. 325.

against the use of highly expansive liquids instead of mercury is the difficulty of allowing for the expansion of the liquid in the stem, if it is not at the same temperature as the bulb. With the same difference of temperatures in different parts of the instrument, the error on this account is clearly in simple proportion to the expansibility of the liquid; and therefore, the residual error due to want of perfect accuracy in the data for the allowance will, generally speaking, be greater with the more expansive than with the less expansive liquid. But in every case in which the bulb and stem can all conveniently be kept at one temperature, a thermometer having for its thermometric substance some highly expansive oil or alcohol or ether, or other so-called organic liquid of perfectly permanent chemical constitution, cannot but be much more accurate and sensitive than the mercury thermometer, which has hitherto been used almost exclusively in thermometric work of the highest rank. We shall see (§§ 62. and 64-66) that the ultimate standard for thermometry, according to the absolute thermodynamic scale (§ 34), is practically attained by the use of hydrogen or nitrogen gas as the thermometric substance, but that for ordinary use a gas thermometer can scarcely be made as convenient as one in which the thermometric substance is a liquid. For practical thermometry of the most accurate kind it seems that the best plan will be to use as ordinary working standard thermometers highly sensitive thermometers constructed of some chosen "organic" liquid, and graduated according to the absolute thermodynamic scale, by aid of the thermodynamically corrected air thermometer (§ 62) used as ultimate standard of reference. The great convenience of the mercury thermometer in respect to freedom from liability to distillation and smallness of error on account of difference of temperature between the bulb and stem renders it the most convenient for a large variety of scientific and practical purposes in which the most minute accuracy or the most extreme sensibility is not required.

§ 24. Without any thermodynamic reason for preferring air to mercury as thermometric fluid, Regnault preferred it for two very good reasons. (1) Its expansion is 20 times that of mercury and 160 times the cubical expansion of glass, and therefore with air the error due to irregularity in the expansion of the glass is 20 times smaller than with mercury, and small enough to produce no practical defalcation from absolute accuracy in thermometry, as he found by elaborate and varied trials. So far as this is concerned, some highly expansive organic liquids would answer nearly as well as air for thermometric fluid, and would have the advantage of giving a thermometer much more easily used. (2) For an ultimate standard of reference air has the advantage over organic liquids generally, that different samples of it taken at different times, or in different parts of the world, and purified of water and carbonic acid¹ by well-known and easily practised processes, are sufficiently uniform to give thermometric results between which the

ing, before becoming stationary, a little of the liquid lags behind the descending free surface, detained on the glass, and trickling slowly down to rejoin the main column, must be waited for before the stationary temperature can be correctly read. We believe that if a fairly inviscid (or mobile) liquid such as alcohol or ether or butyrate of oxide of methyl be used, there will be practically no time lost from this cause, and certainly no accuracy lost when proper care is taken by the observer. The observer must be on his guard against a possibly false steadiness, through the falling of temperature being momentarily balanced in its effect on the free surface by the trickling down of liquid from the glass above, when the free surface is still above, or, it may be, has gone down to a little below, the true position for the final temperature.

¹ Henceforth, to avoid circumlocutions, the unqualified word "air" will be used to denote atmospheric air taken in any part of the world, and deprived of carbonic acid and whatever vapour of water it may have contained, by aid of hydrated lime, or caustic potash, or some other suitable reagent for removing the carbonic acid, and quicklime, or chloride of calcium, or sulphuric acid, or phosphoric acid, for removing the water.

accordance is practically perfect, provided the thermometric plan according to which the different samples are used is the same, or as approximately the same as is easily secured in practice. Two plans for the thermometric use of air naturally present themselves:—(I.) augmentation of volume of air kept in constant pressure; and (II.) augmentation of pressure of air kept in constant volume. Regnault tried both plans, but found that he could only arrange his apparatus to give good results by the second, and on it therefore he founded what he called his "normal air thermometer." For the sake of perfect definiteness he chose, as the density of the air in his normal thermometer, the density which air has when at the temperature of melting ice and under the pressure of one atmo. He adopted the centigrade scale in respect to the marking of the freezing and boiling points by 0° and 100°; and the principle which he assumed for the reckoning of other temperatures was to call equal those differences of temperature for which differences of pressure of the air in his normal thermometer are equal. Thus he was led to a definition of temperature expressed by the following formula:—

$$t = 100 \frac{p - \Pi}{2100 - \Pi}, \dots \dots \dots (1)$$

where Π denotes the pressure one atmo, and p and p_{100} the pressures of the air of the normal thermometer at the temperatures denoted by t and by 100 respectively, the latter being the temperature of steam issuing from water boiling under the pressure of one atmo. By the most accurate observations which he could make Regnault found for his "normal air" $p_{100} = 1.3665 \times \Pi$. Hence his thermometric formula becomes

$$t = 100 \frac{p - \Pi}{.3665 \times \Pi} = 272.85 \left(\frac{p}{\Pi} - 1 \right) \dots \dots \dots (2)$$

§ 25. Regnault compared with his normal air thermometer thermometers on the same plan of constant volume, but with air at other than the normal density of 1 atmo, and with other gases than air; also air and gas thermometers on the plan of constant apparent volume as measured in a glass bulb and stem; also a thermometer founded simply on the dilatation of mercury; also thermometers of mercury in different kinds of glass, each graduated on the glass stem with divisions corresponding to exactly equal volumes of the bore; also overflowing thermometers (thermomètres à déversement), in which a bulb with a short piece of fine stem was perfectly filled with mercury at 0° and the quantity of mercury expelled by the high temperature to be measured was weighed, instead of being volumetrically measured by divisions of a long stem as in the ordinary thermometer.

The whole of this thermometric investigation is full of scientific interest, and abounds with results of great practical value in respect even of the minutest details of Regnault's work. It will be found fully described in the first of his three volumes, entitled *Relation des Expériences entreprises par ordre de Monsieur le Ministre des Travaux Publics et sur la proposition de la Commission centrale des Machines à Vapeur pour Déterminer les Principales Lois et Données Numériques qui entrent dans le Calcul des Machines à Vapeur*, which were published at Paris in 1847, 1862, and 1870. Here we can but state some of the most important of the general conclusions:—

(1) The air thermometers with pressure at 0° of from 44 to 149 centimetres of mercury agreed perfectly with the normal air thermometer calculated according to the same formula (2), and nearly the same numerical coefficient 272.85. A slightly larger value 272.98 (or .0036632⁻¹) gave the best agreement for the 44 c.m. pressure, and the somewhat smaller value 272.7 (or .003667⁻¹) for the pressure 149 c.m.

(2) The hydrogen gas thermometer, with pressure one atmo at 0°, and with its indications calculated according to

Regnault's comparison of thermometers.

formula (2) but with a different numerical coefficient,¹ agreed perfectly with the normal air thermometer from 0° to 325°.

(3) The carbonic acid gas thermometer with pressure 46 c.m. at 0°, and its indications calculated with the coefficient 271.59 ($\cdot 003682^{-1}$), agreed perfectly with the normal air thermometer from 0° to 308°.

(4) The carbonic acid gas thermometer with pressure, at 0°, 74 centimetres (or nearly 1 atmo), calculated with the coefficient 270.64 ($\cdot 003695^{-1}$) to make it agree with the normal air thermometer at 100°, gave numbers somewhat too large for all temperatures from 200° to 323°. The difference seemed to rise to a maximum at about 180°, when it was about $\frac{1}{3}$ °, and to diminish so as to be only about $\frac{1}{10}$ ° at the highest temperatures of the comparison. Two sulphurous acid gas thermometers, with pressures 59 c.m. and 75 c.m. at 0°, calculated with coefficients 263.6 ($\cdot 003794^{-1}$) and 261.4 ($\cdot 003825^{-1}$) respectively to make them agree at 100° with the normal air thermometer, each gave numbers too small for the higher temperatures by differences increasing gradually from $\frac{1}{2}$ ° at 140° to 3° at 320°.

(5) Air and gas thermometers calculated according to differences of pressure of the gas kept at the same apparent volume (that is to say, with the bounding mercury column at a constant mark on the glass stem of the thermometer) gave numbers too small at the higher temperatures by differences gradually increasing up to 2 $\frac{1}{4}$ ° at 350° in the case of *Choisi le Roi* crystal, a hard glass without lead, and to as much as 3 $\frac{1}{4}$ ° in the case of ordinary glass.

In connexion with these observations Regnault remarks that the greatest cause of uncertainty in his air thermometry is the allowance for expansion of the glass. It was only by most carefully made special experiments² on each particular bulb and tube, to determine its expansion throughout the range for which it was to be used, that he succeeded in obtaining the great accuracy which we find in his results, according to which the probable error, whether by his normal air thermometer, or by other air or gas thermometers of those stated above to agree with it perfectly, was not more than from $\cdot 1$ to $\cdot 15$ of a degree for any temperature up to 350°.

(6) The mercury-in-glass thermometers which Regnault generally used for comparison with his normal air thermometer were overflowing thermometers, because he found that with such he could more easily obtain the very minute accuracy at which he aimed than with the ordinary volumetric thermometers; but the formula by which he calculated temperature from the overflowing thermometer was adapted to give exactly the same result as would have been obtained by the ordinary thermometer with divisions on the stem corresponding to equal volumes of the bore. It must be remembered, however, that this perfect agreement between the volumetric and overflowing thermometers would not be found unless the expansion of the bulb and tube were uniform and isotropic throughout.

(7) The general results of Regnault's comparisons of mercury thermometers with his normal air thermometer

¹ Instead of the $\cdot 003665$ of his normal air thermometer, Regnault states that for his hydrogen thermometer he used $\cdot 003652$ (which would make the coefficient in formula (2) be 273.82 instead of 272.85). But this must surely be a mistake, as he found $\cdot 0036678$ for the "coefficient of dilatation" of hydrogen calculated from its increase of pressure in constant volume, and $\cdot 0036613$ for the coefficient of dilatation observed directly for hydrogen under constant pressures of from 1 to 4 atmos (pp. 78, 80, 91, 115, 116), and he nowhere speaks of having found any smaller value than $\cdot 003661$ for hydrogen.

² These experiments were made by finding the weight of mercury contained in each bulb and tube at several different temperatures throughout the range through which it was to be used, and thence calculating the bulks according to the density of mercury for the different temperatures found by his independent investigation of the absolute dilatation of mercury by the hydrostatic method, this method being independent of the expansion of the containing glass or other solid.

were given by himself in a diagram of curves from which the accompanying is copied on a reduced scale (fig. 3). It shows that at a temperature of 320° the independent mercury thermometer stands at 329.8°, the thermometer of mercury in *Choisi le Roi* crystal at 327.25°, and the thermometer of mercury in ordinary glass at 321.8°; and that the independent mercury thermometer and the mercury in *Choisi le Roi* crystal stand 10° higher than the normal air thermometer at the temperatures by it of 323° and 345° respectively.

§ 26. The curve for the independent mercury thermometer is merely Regnault's graphic representation of his experiments on the absolute expansion of mercury (*Relation des Expériences*, vol. i. p. 328). It shows that the addition of bulk given to the same mass of mercury under constant pressure by elevation of temperature is for the same difference of temperatures as indicated by his normal air thermometer regularly greater and greater the higher the temperature.

§ 27. It is interesting to see by the diagram that at the high temperatures all the mercury thermometers keep nearer to the air thermometer than does the independent mercury thermometer, and that the mercury in ordinary soft

glass keeps much nearer to the air thermometer than does the mercury in the hard *Choisi le Roi* glass. We infer that, still reckoning temperature by the air thermometer, we have regular augmentation of expansion at the high temperatures in all the different glasses, each greater than the augmentation of expansion of mercury, and that this augmentation is greater in the soft ordinary glass than in the hard *Choisi le Roi* glass, being in the ordinary glass great enough to overcompensate in the resulting thermometric indication the augmenting expansion of the mercury from 100° to 245°; while above 245° in the ordinary glass thermometer, and at all temperatures above 100° in the *Choisi le Roi* thermometer, the compensation is only partial. Between 0° and 100° the independent mercury thermometer stands regularly lower than the air thermometer by as great a difference as $\cdot 35$ ° at 50°, where it is a maximum. The curves for the mercury-in-glass thermometers are not shown between 0° and 100°, but it is clear from the diagram that the *Choisi le Roi* thermometer must, like the independent mercury thermometer, stand lower than the air thermometer, but by a smaller difference, probably only about $\cdot 2$ ° at 50°; and the ordinary glass thermometer higher than the air thermometer from 0° to 100° by a difference which may be $\cdot 2$ ° or $\cdot 3$ ° at 50°. This last inference from the diagram is confirmed by Regnault's table of results facing page 227 of his first volume.

§ 28. In the best modern thermometers the graduations are actually engraved on the glass; but in most popular thermometers, and in many for scientific investigation, they are on an attached scale Fig. 4. of wood, or ivory, or brass, or paper. Some of the best popular thermometers are the German bath thermometers, in which the graduation is on a paper scale guarded by being enclosed in a wide glass tube hermetically sealed round the stem and over the bulb of the glass which contains the mercury, in the manner shown in fig. 4.

Fig. 3.

The graduation is clearer and more easily read in this kind of thermometer than in any other. The complete protection of the paper scale against damp and damage afforded by its hermetically sealed glass envelope gives a personally enduring quality to this form of thermometer,¹ such as is possessed by no others except those graduated on the glass; and the lightness of the paper renders its proper attachment to the inner stem, by gum or otherwise, thoroughly trustworthy, when once well done by the maker of the instrument. For scientific purposes the paper scale was too cheap, and common, and good, to satisfy the ideas of those instrument makers who in Germany and France substituted the heavy graduated slab of opal glass for the paper, while still adhering to the bath thermometer pattern in hermetically enclosing this scale in an outer containing glass tube,—very unnecessarily, as the glass scale, unlike the paper scale, does not require any such protection.

This is now, however, a thing of the past. At the present time all high-class scientific thermometers are graduated on the glass of the stem without any attached scale of other material. Except in respect to ease of reading the indications this simplest form is, both for popular and for scientific purposes, superior even to the German bath thermometer with hermetically sealed paper scale; and this will be the form intended when we speak of a mercury thermometer, or a spirit thermometer, or a liquid thermometer, without any special qualification.

§ 29. *Properties of Matter concerned in Liquid Thermometers.*—The indications of the liquid thermometer depend not only upon the expansion of the liquid with heat; they are seriously modified by the expansion experienced also by the containing solid. The instrument in fact consists of a glass measure measuring the bulk of a liquid. If the bulk of the hollow space in the glass and the bulk of the liquid expand by the same amount, the apparent bulk of the liquid as thus measured will remain unchanged. Now, supposing the glass to be perfectly homogeneous and isotropic (see art. ELASTICITY, §§ 38, 39, and chap. I. of Mathematical Theory), and the bulb to be free from internal strain, the glass will, when warmed uniformly, expand equally in all directions, and the volume of the hollow space will be altered in the same ratio as the volume of the glass itself. Hence the indications of the thermometer depend on a difference between the expansion of the glass and the expansion of the liquid.

§ 30. To define exactly the indications of a thermometer founded on the expansion of a fluid,² let the volume of the bore of the stem between two consecutive divisions be called for brevity a *degree measure*. The degree measure is habitually made as nearly as possible equal throughout the scale in the best mercury-in-glass thermometers; and, as we shall see (§ 62), it ought to be so in an air thermometer to give indications agreeing with the absolute thermodynamic scale nearly enough for the most accurate practical thermometry. But in practical spirit-thermometers the divisions are made to correspond as nearly as may be to degrees of a standard mercury or air

thermometer, and the degree measures are therefore (Table II. below) larger and larger from the lower to the upper end of the scale. For the purpose, however, of comparing the thermometric performances of different liquids, we shall suppose the degree measure to be of equal volume throughout the scale in each case.

Let N be the number of degree measures contained in the volume of the bulb and stem up to the point marked zero on the scale; and let D_t denote the volume, at any temperature t , of the degree measure reckoned in absolute units of volume. The volume of the bulb and stem up to zero will be ND_0 . On the supposition of perfect isotropy and freedom from strain in the glass, N will be independent of the temperature and D_t/D_0 will be the ratio of the volume of any portion of the glass at temperature t to its volume at the temperature called zero, if D_0 denote the volume of the degree measure when the glass is at this zero temperature. Let now L_t and L_0 denote the volumes of the whole liquid in a thermometer at the two temperatures t and 0 ; we have $L_0 = ND_0$. And if s be the number of scale divisions marking the place of the liquid surface in the thermometer tube, we have $L_t = (N + s)D_t$. Hence

$$L_t = (N + s)D_t = ND_0 \left(\frac{L_t/L_0}{D_t/D_0} \right) = ND_0 (1 + E_t) \left(\frac{L_t/L_0}{D_t/D_0} \right)$$

denote augmentation of bulk of the liquid, and E_t augmentation of bulk of each degree-division of the stem, when temperature is raised from 0 to t , each reckoned in terms of the bulk at zero temperature, we have

$$s = N \left(\frac{1 + E_t}{1 + E_0} - 1 \right) = N \frac{E_t - E_0}{1 + E_0}$$

This is the formula for the ordinary liquid thermometer. It is also applicable to the constant pressure air thermometer, in which, with proper instrumental means to keep the pressure constant, air is allowed to expand or contract with elevation or depression of temperature, and its volume is measured in a properly shaped glass measuring vessel. We may arbitrarily determine to take s as the numeric for the temperature which is indicated by any one particular thermometer of this kind, for instance, a methyl butyrate thermometer, or an alcohol thermometer, or a mercury or an air thermometer. But if $s = t$ for any one individual thermometer, it cannot be exactly so for any other. In the first advances towards accurate thermometry it was taken so for the mercury-in-glass thermometer, and by general consent it was continued so until it was found (§ 25) that different mercury-in-glass thermometers, each made with absolute accuracy, differ largely in their reckonings of temperature.

§ 31. *Numerical Thermometry.*—In § 12 above, a perfectly definite and very simple basis for numerical thermometry was described, not as having been adopted in practice, but as an illustration of a very general principle upon which reckoning of temperature may be done in numbers. The principle is this. Two definite temperatures depending on properties of some particular substance or substances are first fixed upon and marked by two arbitrary numbers,—as, for instance, the temperature of melting ice marked zero, and the temperature of steam issuing from boiling water under atmospheric pressure of exactly one atmo, marked 100. Then any intermediate temperature t is obtained by taking t parts of water at zero and $(100 - t)$ parts at 100° and mixing them together. As said in § 12 this method is limited to temperatures at which liquid water can be obtained, and therefore practically it is only applicable between the melting point of ice and the boiling point of water, under ordinary atmospheric pressure.

Thermometer defined to make constant the specific heat of water

§ 32. Any other liquid of permanent chemical constitution might be used instead of water as the thermometric substance in thermometry founded on mixtures; so even might a powdered solid. Oil if used instead of water would have the advantage of being available for higher temperatures; but want of perfect definiteness and constancy of chemical constitution is a fatal disqualification for it as the fundamental thermometric substance for ther-

Fig. 5.

¹ Provided it is never exposed to "browning" temperatures (or temperatures high enough to produce partially destructive distillation of the paper). Instrument makers ignoring this caution have actually made it with graduation extending to such temperatures for kitchen use. The result is that it gets injured to the extent of partially browning the hermetically sealed paper, and befogging the inner surface of the glass envelope, by applying it to test the temperature of melted fat in cooking. For this purpose the simple scientific thermometer with graduation on the glass stem is proper.

metry by mixtures. Liquid mercury might be used with the advantage of being available for both higher and lower temperatures than water, through a much wider whole range indeed than either water or oil. For use as thermometric substance for the method of mixtures both water and mercury, in the conditions of approximate purity in which they are easily obtained in abundance, have a paramount advantage over all other liquids, in near enough approximation to perfect definiteness and constancy of constitution to give practically perfect thermometric results.

§ 33. In §§ 12, 24, 25, 30, 31, 32, several distinct definitions of numerical reckoning of temperature have been given. In each of these the differences of temperature which are to be called equal are defined specially, and this is the essence of the thermometric scale in each case (the marking of 0° and 100° for the "freezing" and "boiling" points being common to all as a matter of practical usage and not an essential of the thermometric principle in any case). Thus in §§ 12, 31, and 32 differences of temperature are called equal which are produced by the communication of equal quantities of heat to a given quantity of the particular thermometric substance chosen—water, for example, or mercury; in other words (§ 68 below), this thermometric system is chosen so as to make the specific heat of a particular thermometric substance the same for all temperatures. Again in § 24 differences of temperature are called equal for which the differences of pressure are equal in air of the particular density which air has if its pressure is one atmo when its temperature is "freezing." This is Regnault's "normal thermometry." In § 25 (1), (2), (3), (4), other reckonings of temperature differing essentially from this, though, as Regnault's experiments proved, by but very small differences, are given simply by the substitution of air of other than Regnault's normal density, and of other gases than air, for the air of Regnault's normal thermometer. In § 25 (5) a thermometry founded on a complex coefficient of change of pressure and volume of a gas and change of volume of some one particular glass vessel is defined and compared with Regnault's normal thermometry; and in § 25 (6) and (7) the same is done for the ordinary mercury-in-glass thermometer, which depends on a coefficient of glass and mercury leading to the reckoning of temperature defined in § 30. Again in § 26 and § 24 (I.) is indicated a system of thermometry founded on the absolute dilatation of some fluid, such as mercury or alcohol or butyrate of oxide of methyl or other permanent liquid or air, at some constant pressure, such as one atmo, with equal differences of temperature defined as those which give equal dilatations of the particular substance chosen as the thermometric fluid.

§ 34. Each of all these different definitions of temperature is founded on some particular property of a particular substance. A thermometer graduated to fulfil one of the definitions for one particular substance would not agree with another thermometer graduated according to the same definition for another substance, or according to some of the other definitions. A much more satisfactory foundation for thermometry is afforded by thermodynamic science, which (see THERMODYNAMICS) gives us a definition of temperature depending on certain thermodynamic properties of matter in such a manner that if a thermometer is graduated according to it from observation of one class of thermal effects in one particular substance, it will agree with a thermometer graduated according to the same thermodynamic law from the same class of effects in any other substance, or from the same or from some other class of effects in another substance. Thus we have what is called the absolute thermodynamic scale. This scale is now in modern thermal science the ultimate

scale of reference for all thermometers of whatever kind (§ 67). It is defined in §§ 35 and 37 after the following preliminary. A piece of matter which we shall call the "thermometric body" or "thermometric substance" must be given, and at each instant it must be throughout at one temperature, whatever operations we perform upon it. For simplicity we shall suppose it to be of one substance throughout. It may be all solid, or it may be partly solid and the remainder gaseous (as the contents of a wholly frozen cryophorus¹ or any other form of closed vessel full of ice and vapour of water, but with no air); or it may at one particular temperature in the course of its use be partly solid and partly liquid and partly gaseous (as the contents of a partially frozen cryophorus); or it may be partially liquid and partially gaseous (as the contents of an unfrozen cryophorus or of a "philosopher's hammer");² or it may be all liquid; or it may be all gas; or it may be all fluid at a temperature above the Andrews "critical temperature."³ If it be all solid it may be under any homogeneous stress (ELASTICITY, Mathematical Theory, part i., chap. i.); but in any case we suppose for simplicity the stress to be homogeneous throughout, and therefore if the thermometric body be partly solid and partly fluid, the stress in the solid as well as in the fluid must be *uniform pressure in all directions*. To avoid excluding the case of all solid from our statements, we shall use generally the word *stress*, which will mean normal pressure reckoned in number of units of force per unit of area in every case in which the whole or any part of the thermometric body is fluid, and will denote this or any other possible stress when the thermometric body is all solid.

§ 35. (1) Alter the bulk or shape of the thermometric substance till it becomes warmer to any desired degree. (2) Keeping it now at this higher temperature, alter bulk or shape farther, and generate the heat which the substance takes to keep its temperature constant, by stirring water, or a portion of the substance itself, if it is partly fluid, and measure the quantity of work spent in this stirring. (3) Bring it back towards its original bulk and shape till it becomes cooled to its original temperature. (4) Keeping it at this temperature, reduce it to its original bulk and shape, carrying off, by a large quantity of water, the heat which it must part with to prevent it from becoming warmed. Find by a special experiment how much work must be done to give an equal amount of heat to an equal amount of water by stirring. Then the ratio of the first measured quantity of work to the second is the ratio of the higher temperature to the lower on the absolute thermodynamic scale.

§ 36. The following is equivalent to § 35, and is more convenient for analytical work. It is derived from § 35 by supposing the first and third operations to be so small that the ratio defined as the ratio of the two temperatures is infinitely nearly unity, and conversely § 35—our first form of definition of absolute temperature—may be derived from the second, which is to be now given, by passing through a finite range of temperature by successive infinitesimal steps, and applying the second definition to each step.

§ 37. Let the thermometric body be infinitesimally warmed by stirring a portion or the whole of itself if it be partially or wholly fluid, or by stirring a quantity of fluid in space around it if it be all solid; and during the process let the stress upon the body be kept unchanged. The body expanding or contracting or changing its shape with the heat, as the case may be, does work upon the surrounding material by which its stress is maintained.

¹ See articles LIQUID, MATTER (PROPERTIES OF), and STEAM.

² *Ibid.*

³ *Ibid.*

Each founded on a particular property of a particular substance.

First definition:—by ratio of two temperatures.

Carnot's thermodynamic cycle generalized.

Find the ratio of the amount of work thus done to the amount of work spent in the stirring. For brevity we shall call this the work-ratio. Again, let the stress be infinitesimally increased, the thermometric body being now for the time enclosed in an impermeable envelope so that it may neither gain nor lose caloric. It will rise (or fall)¹ in temperature in virtue of the augmentation of stress. *The ratio of this infinitesimal elevation of temperature to the whole absolute temperature is equal to the work-ratio multiplied into the ratio of the infinitesimal augmentation of stress to the whole stress.*

§ 38. To show how our definition of absolute temperature is to be applied in practice take the following examples. Example 1.—Any case in which the thermometric substance is part in one condition and the remainder in another of different density, as part solid and part vapour, or part solid and part liquid, or part liquid and part steam. In this last case, as explained above (§ 34), we suppose the stress to be uniform pressure in all directions.

Let p be its amount, and let t be the absolute temperature corresponding to this pressure. Let σ be the ratio of the density of the rarer to that of the denser portion, ρ the density of the rarer portion, and $J\kappa$ the quantity of work required to generate the heat taken to convert unit mass of the substance from the lower to the higher condition (κ the "latent heat" of transition from the lower to the higher condition per unit mass of the substance, and J the dynamical equivalent of the thermal unit in which κ is measured). The work done by the substance in passing from the denser to the rarer condition per unit volume of the latter is $p(1-\sigma)$, and the amount of work required to generate the heat taken in doing so is $J\rho\kappa$. Hence the work-ratio of our second definition is

$$\frac{p(1-\sigma)}{J\rho\kappa}, \dots \dots \dots (1).$$

Let now the pressure be increased by an infinitely small quantity dp , and, the substance being still in the two conditions but of uniform temperature throughout, let dt be the corresponding rise in temperature. We have by the definition (§ 37)

$$\frac{dt}{t} = \frac{p(1-\sigma) dp}{J\rho\kappa p} = \frac{1-\sigma}{J\rho\kappa} dp.$$

Hence
$$\frac{1}{t} \cdot \frac{dt}{dp} = \frac{1-\sigma}{J\rho\kappa} \dots \dots \dots (2).$$

Hence by integration

$$\log \frac{t}{t_0} = \int_{p_0}^p \frac{(1-\sigma) dp}{J\rho\kappa} \dots \dots \dots (3).$$

or
$$t = t_0 \epsilon^{\int_{p_0}^p \frac{(1-\sigma) dp}{J\rho\kappa}} \dots \dots \dots$$

§ 39. Fig. 6 represents a thermometer constructed to show absolute temperature on the plan of example 1, § 38, realized for the case of water and vapour of water as thermometric substance. The containing vessel consists of a tube with cylindric bulb like an ordinary thermometer; but, unlike an ordinary thermometer, the tube is bent in the manner shown in the drawing. The tube may be of from 1 to 2 or 3 millims. bore, and the cylindrical part of the bulb of about ten times as much. The length of the cylindrical part of the bulb may be rather more than $\frac{1}{100}$ of the length of the straight part of the tube. The contents, water and vapour of water, are to be put in and the glass hermetically sealed to enclose them, with the utmost precautions to obtain pure water as thoroughly freed from air as possible, after better than the best manner of instrument makers in making cryophoruses and water hammers. The quantity of water left in at the sealing must be enough to fill the cylindrical part of the bulb and the horizontal branch of the tube. When in use the straight part of the tube must be vertical with its closed end up, and the part of it occupied by the manometric water-column must be kept at a nearly enough definite temperature by a sur-

rounding glass jacket-tube of iced water. This glass jacket-tube is wide enough to allow little lumps of ice to be dropped into it from its upper end, which is open. By aid of an india-rubber tube connected with its lower end, and a little movable cistern, as shown in the drawing, the level of the water in the jacket is kept from a few inches above to a quarter of an inch below that of the interior manometric column. Thus, by dropping in lumps of ice so as always to keep some unmelted ice floating in the water of the jacket, it is easy to keep the temperature of the top of the manometric water-column exactly at the freezing temperature. As we shall see presently, the manometric water below its free surface may be at any temperature from freezing to 10° C. above freezing without more than $\frac{1}{10}$ per cent. of hydrostatic error. The temperature in the vapour-space above the liquid column may be either freezing or anything higher. It ought not to be lower than freezing, because, if it were so, vapour would condense as hoar frost on the glass, and evaporation from the top of the liquid column would either cryophoruswise (see LIQUID and THERMODYNAMICS) freeze the liquid there, or would cool it below the freezing point.

§ 40. The chief object of keeping the top of the manometric column exactly at the freezing point is to render perfectly definite and constant the steam pressure in the space above it.

A second object of considerable importance when the bore of the tube is so small as one millimetre is to give constancy to the capillary tension of the surface of the water. The elevation by capillary attraction of ice-cold water in a tube of one millimetre bore is about 7 millims. The constancy of temperature provided by the surrounding iced water will be more than sufficient to prevent any perceptible error due to inequality of this effect. To avoid error from capillary attraction the bore of the tube ought to be very uniform, if it is so small as one millimetre. If it be three millimetres or more, a very rough approach to uniformity would suffice.

A third object of the iced-water jacket, and one of much more importance than the second, is to give accuracy to the hydrostatic measurement by keeping the density of the water throughout the long vertical branch definite and constant. But the density of water at the freezing point is only $\frac{1}{10}$ per cent. less than the maximum density, and is the same as the density at 8° C.; and therefore when $\frac{1}{10}$ per cent. is an admissible error on our thermometric pressure, the density will be nearly enough constant with any temperature from 0° to 10° C. throughout the column. But on account of the first object mentioned above the very top of the water column must be kept with exceeding exactness at the freezing temperature.

§ 41. In this instrument the "thermometric substance" (§ 34) is the water and vapour of water in the bulb, or more properly speaking the portions of water and vapour

Fig. 6.

Water-steam thermometer.

¹ In the case of fall the elevation of temperature is to be regarded as negative, and in this case the "work-ratio" is negative also.

of water infinitely near their separating interface. The rest of the water is merely a means of measuring hydrostatically the fluid pressure at the interface. When the temperature is so high as to make the pressure too great to be conveniently measured by a water column, the hydrostatic measurement may be done, as shown in the annexed drawing (fig. 7), by a mercury column in a glass tube, surrounded by a glass water jacket not shown in the drawing, to keep it very accurately at some definite temperature so that the density of the mercury may be accurately known.

The simple form of steam thermometer represented with figured dimensions in fig. 6 will be very convenient for practical use for temperatures from freezing to 60°. Through this range the pressure of water-steam, reckoned in terms of the balancing column of water of maximum density, increases (Table V.) from 6¼ to 202.3 centimetres; and for this therefore a tube of a little more than 2

Fig. 7.

metres will suffice. From 60° to 140° the pressure of steam now reckoned in terms of the length of a balancing column of mercury at 0° increases from 14.88 to 271.8 centimetres; and for this a tube of 280 centimetres may be provided. For higher temperatures a longer column, or several columns, as in the multiple manometer, or an accurate air pressure-gauge, or some other means, such as a very accurate instrument constructed on the principle of Bourdon's metallic pressure-gauge, may be employed, so as to allow us still to use water and vapour of water as thermometric substance.

§ 42. At 230° C., the superior limit of Regnault's high-pressure steam experiments, the pressure is 27.53 atmos, but there is no need for limiting our steam thermometer to this temperature and pressure. Suitable means can easily be found for measuring with all needful accuracy much higher pressures than 27 atmos. But at so high a temperature as 140°, vapour of mercury measured by a water column, as shown in the diagram (fig. 8), becomes available for purposes for which one millimetre to the degree is a sufficient sensibility. The mercury-steam-pressure thermometer, with pressure measured by water-column, of dimensions shown in the drawing, serves from 140° to 280° C., and will have very ample sensibility through the upper half of its scale. At 280° its sensibility

will be about 4¼ centimetres to the degree! For temperatures above 280° sufficient sensibility for most purposes is obtained by substituting mercury for water in that simplest form of steam thermometer shown in fig. 6, in which the pressure of the steam is measured by a column of the liquid itself kept at a definite temperature. When the liquid is mercury there is no virtue in the particular temperature 0° C., and a stream of water as nearly as may be of atmospheric temperature will be the easiest as well as the most accurate way of keeping the mercury at a definite temperature. As the pressure of mercury steam is at all ordinary atmospheric temperatures quite imperceptible to the hydrostatic test when mercury itself is the balancing liquid, that which was the chief reason for fixing the temperature at the interface between liquid and vapour at the top of the pressure-measuring column when the balancing liquid was water (§ 40) has no weight in the present case; but, on the other hand, a much more precise

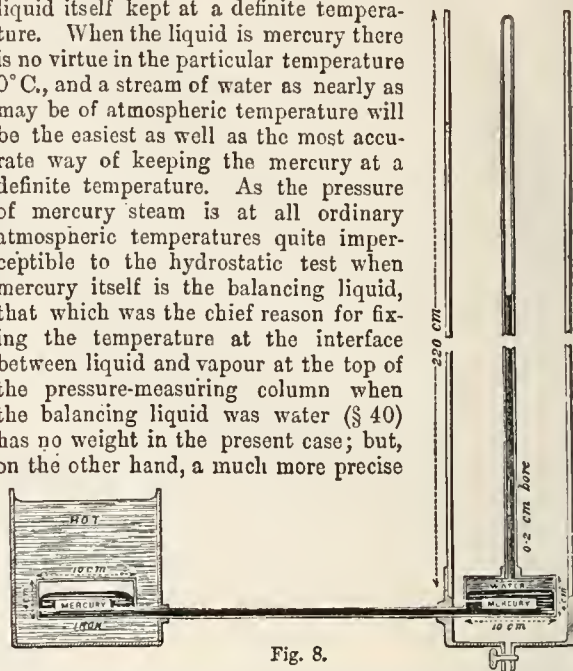

Fig. 8.

definiteness than the ten degrees latitude allowed in the former case for the temperature of the main length of the manometric column is now necessary. In fact, a change of temperature of 2.2° in mercury at any atmospheric temperature produces about the same proportionate change of density as is produced in water by a change of temperature from 0° to 10°, that is to say, about 1/10 per cent.; but there is no difficulty in keeping, by means of a water jacket, the mercury column constant to some definite temperature within a vastly smaller margin of error than 2.2°, especially if we choose for the definite temperature something near the atmospheric temperature at the time, or the temperature of whatever abundant water supply may be available. If the vertical tube for the pressure-measuring mercury column be 830 centimetres long, the simple mercury-steam thermometer may be used up to 520° C., the highest temperature reached by Regnault in his experiments (Table V. below) on mercury-steam. By using an iron bulb and tube for the part of the thermometer exposed to the high temperature, and for the lower part of the measuring column to within a few metres of its top, with glass for the upper part to allow the mercury to be seen, a mercury-steam-pressure thermometer can with great ease be made which shall be applicable for temperatures giving pressures up to as many atmospheres as can be measured by the vertical height available. The apparatus may of course be simplified by dispensing with the Torricellian vacuum at the upper end of the tube, and opening the tube to the atmosphere, when the steam-pressure to be measured is so great that a rough and easy barometer observation gives with sufficient accuracy the air-pressure at the top of the measuring column. The easiest, and not necessarily in practice the least accurate, way of measuring very high pressures of mercury-steam will be by enclosing some air above the cool pressure-measuring column of mercury, and so making it into a compressed-air pressure-gauge, it being understood that the law of compression of the air under the pressures for which it is to be used

in the gauge is known by accurate independent experiments such as those of Regnault on the compressibility of air and other gases.

§ 43. The water-steam thermometer may be used, but somewhat precariously, for temperatures below the freezing point, because water, especially when enclosed and protected as the portion of it in the bulb of our thermometer is, may be cooled many degrees below its freezing point without becoming frozen: but, not to speak of the uncertainty or instability of this peculiar condition of water, the instrument would be unsatisfactory on account of insufficient thermometric sensibility for temperatures more than two or three degrees below the freezing point. Hence, to make a steam thermometer for such temperatures some other substance than water should be taken, and none seems better adapted for the purpose than sulphurous acid, which, in the apparatus represented with figured dimensions in the accompanying diagram (fig. 9), makes an admirably convenient and sensitive thermometer for temperatures from + 20° to something far below - 30°, as we see from the results of Regnault's measurements (Table VI. below).

§ 44. To sum up, we have in §§ 39 . . 43 a complete series of steam-pressure thermometers, of sulphurous acid, of water, and of mercury, adapted to give absolutely definite and highly sensitive thermometric indications throughout the wide range from something much below - 30° to considerably above 520° of the centigrade scale. The graduation of the scales of these thermometers to show absolute temperature is to be made by calculation from formula (3) of § 38, when the requisite experimental data, that is to say, the values of σ and $\rho\kappa$ for different values of p throughout the range for which each substance is to be used as thermometric fluid are available. Hitherto these requisites have not been given by direct experiment for any one of the three substances with sufficient accuracy for our thermometric purpose through any range whatever. Water, naturally, is the one for which the nearest approach to the requisite information has been obtained. For it Regnault's experiments have given, no doubt with great accuracy, the values of p (the steam pressure) and of κ (the latent heat of steam per unit mass) for all temperatures reckoned by his normal air thermometer, which we now regard merely as an arbitrary scale of temperature, through the range from - 30° to + 230°. If he, or any other experimenter, had given us with similar accuracy through the same range the values of ρ (the density of steam) and σ (the ratio of the density of steam to the density of water in contact with it), for temperatures reckoned on the same arbitrary scale, we should have all the data from experiment required for the graduation of our water-steam thermometer to absolute thermodynamic scale. For it is to be remarked that all reckoning of temperature is eliminated from the second member of formula (3), and that in our use of it Regnault's normal thermometer has merely been referred to for the values of $\rho\kappa$ and of $1 - \sigma$, which correspond to stated values of p . The arbitrary constant of integration, t_0 , is truly arbitrary. It will be convenient to give it such a value that the difference of values of t between the

Fig. 9.

freezing point of water and the temperature for which p is equal to one atmo shall be 100, as this makes it agree with the centigrade scale in respect to the difference between the numbers measuring the temperatures which on the centigrade scale are marked 0° and 100°. We shall see (§ 56 below) that indirectly by means of experiments on hydrogen gas this assignation of the arbitrary constant of integration would give 273 for the absolute temperature 0° C., and 373 for that of 100° C. Meantime, as said above, we have not the complete data from direct experiments even on water-steam for graduating the water-steam thermometer; but on the other hand we have, from experiments on air and on hydrogen and other gases, data which allow us to graduate indirectly any continuous intrinsic thermoscope (§ 19 above) according to the absolute scale; and we shall see that by thus indirectly graduating the water-steam thermometer, we learn the density of steam at different temperatures more accurately than it has hitherto been made known by any direct experiments on water-steam itself.

§ 45. Merely viewed as a continuous intrinsic thermoscope, the steam thermometer, in one or other of the forms described above to suit different parts of the entire range from the lowest temperatures to temperatures somewhat above 520°, is no doubt superior in the conditions for accuracy specified in § 16 to every other thermoscope of any of the different kinds hitherto in use; and it may be trusted more surely for accuracy than any other as a thermometric standard when once it has been graduated according to the absolute scale, whether by practical experiments on steam, or indirectly by experiments on air or other gases. In fact, the use of steam-pressure measured in definite units of pressure, as a thermoscopic effect, in the steam thermometer is simply a continuous extension to every temperature of the principle already practically adopted for fixing the temperature which is called 100° on the centigrade scale; and it stands on precisely the same theoretical footing as an air thermometer, or a mercury-in-glass thermometer, or an alcohol thermometer, or a methyl butyrate thermometer, in respect to the graduation of its scale according to absolute temperature. Any one intrinsic thermoscope may be so graduated ideally by thermodynamic experiments on the substance itself without the aid of any other thermometer or any other thermometric substance; but the steam-pressure thermometer has the great practical advantage over all others, except the air thermometer, that these experiments are easily realizable with great accuracy instead of being, though ideally possible, hardly to be considered possible as a practical means of attaining to thermodynamic thermometry. In fact, for water-steam it is only the most easily obtained of experimental data, the measurement of the density of the steam at different pressures, that has not already been actually obtained by direct experiment. Whether or not, when this lacuna has been filled up by direct experiments, the data from water-steam alone may yield more accurate thermodynamic thermometry than we have at present from the hydrogen or nitrogen gas thermometer (§§ 64 . . 69 below), we are unable at present to judge. But when once we have the means, directly from itself, or indirectly from comparison with hydrogen or nitrogen or air thermometers, of graduating once for all a sulphurous acid steam thermometer, water-steam thermometer, or mercury-steam thermometer, that is to say, when once we have a table of the absolute thermodynamic temperatures corresponding to the different steam pressures of the substances sulphurous acid, water, and mercury, we have a much more accurate and more easily reproducible standard than either the air or gas thermometer of any form, or the mercury thermometer, or any liquid thermometer can give.

In fact, the series of steam thermometers for the whole range from the lowest temperatures can be reproduced with the greatest ease in any part of the world by a person commencing with no other material than a piece of sulphur and air to burn it in,¹ some pure water, and some pure mercury, and with no other apparatus than can be made by a moderately skilled glass-blower, and with no other standard of physical measurement of any kind than an accurate linear measure. He may assume the force of gravity to be that calculated for his latitude, with the ordinary rough allowance for his elevation above the sea, and his omission to measure with higher accuracy the actual force of gravity in his locality can lead him into no thermometric error which is not incomparably less than the inevitable errors in the reproduction and use of the air thermometer, or of mercury or other liquid thermometers. In temperatures above the highest for which mercury-steam pressure is not too great to be practically available, nothing hitherto invented but Deville's air thermometer with hard porcelain bulb suited to resist the high temperature is available for accurate thermometry.

§ 46. We have given the steam thermometer as our first example of thermodynamic thermometry because intelligence in thermodynamics has been hitherto much retarded, and the student unnecessarily perplexed, and a mere quicksand has been given as a foundation for thermometry, by building from the beginning on an ideal substance called perfect gas, with none of its properties realized rigorously by any real substance, and with some of them (see MATTER, LIQUID, STEAM) unknown, and utterly unassignable, even by guess. But after having been moved by this reason to give the steam-pressure thermometer as our first theoretical example, we have been led into the preceding carefully detailed examination of its practical qualities, and we have thus become convinced that though hitherto used in scientific investigations only for fixing the "boiling point," and (through an inevitable natural selection) by practical engineers for knowing the temperatures of their boilers by the pressures indicated by the Bourdon gauge, it is destined to be of great service both in the strictest scientific thermometry and as a practical thermometer for a great variety of useful applications.

§ 47. Example 2 (including example 1).—Any case in which the stress is uniform pressure in all directions.

Let p and v denote the pressure and volume. The condition of the substance (single, double, or triple, as the case may be) is determined when p and v are given, and it will therefore be spoken of shortly as the condition (p, v). Let e be the energy which must be communicated to the substance to bring it from any conveniently defined zero condition (p_0, v_0) to any condition whatever (p, v). Remark that e is a function of the two independent variables p, v to be found by experiment, and that the finding of it by experiment is a perfectly determinate practical problem, which can be carried out without the aid of any thermoscope, and without any consideration whatever relating to temperature. We shall see in fact that accurate practical solutions of it for many different substances have been obtained by experiment (see THERMODYNAMICS). The absolute temperature t is also a function of p and v to be also determined by experiment, according to the equivalent definitions of §§ 35 and 37. Let heat be communicated to the substance so as to cause its volume to increase by dv , the pressure being kept constant. The energy of the body will be augmented by

$$\frac{de}{dv} \cdot dv.$$

At the same time the body in expanding and pressing out the matter around it does work to the extent of

$$p \cdot dv \dots \dots \dots (4).$$

Hence the whole work required to generate the heat given to it amounts to

$$\left(\frac{de}{dv} + p\right)dv \dots \dots \dots (5).$$

¹ Practically, the best ordinary chemical means of preparing sulphurous acid, as from sulphuric acid by heating with copper, might be adopted in preference to burning sulphur.

Hence the ratio of (4) to (5), or

$$\frac{p}{\frac{de}{dv} + p} \dots \dots \dots (6),$$

is the "work-ratio" of § 37. Hence by the definition

$$\frac{Dt}{t} = \frac{dp}{p} \frac{p}{\frac{de}{dv} + p} = \frac{dp}{\frac{de}{dv} + p} \dots \dots \dots (7),$$

where Dt denotes the change of temperature produced by augmenting the pressure by dp , and at the same time preventing the substance from either giving heat to or taking heat from the surrounding matter. To express this last condition analytically, let dv be the augmentation of volume (negative, of course, if dp be positive) which it implies. The work done on the substance by the pressure from without is $-pdv$, and the energy of the substance is augmented by just this amount, because of the condition to be expressed. Hence

$$\frac{de}{dv}dv + \frac{dc}{dp}dp = -pdv \dots \dots \dots (8);$$

whence

$$dv = \frac{-\frac{dc}{dp}}{\frac{de}{dv} + p} dp \dots \dots \dots (9).$$

But

$$Dt = \frac{dt}{dp}dp + \frac{dt}{dv}dv,$$

and so we have

$$Dt = \left(\frac{dt}{dp} - \frac{dt}{dv} \frac{dc}{dp}\right) dp \dots \dots \dots (10).$$

Eliminating Dt/dp from this by (7) we find

$$t = \left(p + \frac{de}{dv}\right) \frac{dt}{dp} - \frac{de}{dp} \frac{dt}{dv} \dots \dots \dots (11).$$

§ 48. This is a linear partial differential equation of the first order for the determination of t , supposing, as we do for the present, that e is a known function of p and v . The following graphical illustration of the well-known analytical process for finding the complete solutions of such equations shows exactly how much towards determination of temperature can be done with no other data from experiment than the values of $\frac{de}{dv}$ and $\frac{de}{dp}$ as functions of p and v , and what additional information is required to fully determine t .

First remark that (11) is the condition that $\frac{1}{t}$ be a factor rendering $\left(p + \frac{de}{dv}\right)dv + \frac{de}{dp}dp$ a complete differential of a function² of two independent variables p and v . Let ϕ be this function,—that is to say, let ϕ be such that

or

$$\left. \begin{aligned} \frac{d\phi}{dv} &= \frac{1}{t} \left(p + \frac{de}{dv}\right), \text{ and } \frac{d\phi}{dp} = \frac{1}{t} \frac{de}{dp} \\ t &= \frac{p + \frac{de}{dv}}{\frac{d\phi}{dv}} = \frac{de}{d\phi} \end{aligned} \right\} \dots \dots (12).$$

Called thermodynamic function by Rankine called entropy by Clausius and subsequent writers

Then every solution of the differential equation

$$\frac{dp}{dv} = -\frac{p + \frac{de}{dv}}{\frac{de}{dp}} \dots \dots \dots (13)$$

renders ϕ constant; and conversely, every series of values of p and v which renders ϕ constant constitutes a solution of (13). Now this differential equation may be solved graphically by taking p and v as rectangular coordinates of a point in a plane, and drawing the whole series of curves which satisfy it as follows. Commence with any point and calculate for its values of p and v the value of the second member of (13). Draw through this point an infinitesimal line in the direction of the tangent to the curve given by the value so found for $\frac{dp}{dv}$. With the altered values of p and v corresponding

² This function is of great importance in practical thermodynamics: multiplied by t_0 , it is equal to the excess of the energy of the substance above its motivity. Motivity (defined by Sir Wm. Thomson, *Proceedings R.S.E.*, 1879) is the amount of work obtainable by letting the substance pass from the state (p, v) in which it is given to the zero condition (p_0, v_0), without either taking in heat from or giving out heat to matter at any other temperature than t_0 .—See THERMODYNAMICS.

to the other end of this infinitesimal line, calculate a fresh value of $\frac{d\phi}{dv}$, and continue the curve in the slightly altered direction thus found, and so on. Take another point anywhere infinitesimally near this curve but not in it, and draw by a similar process the curve through it satisfying the equation. Take a third point infinitely near this second curve, and draw through it a third curve satisfying (13), and so on till the whole area of values p, v , possible for the substance in question, is filled with a series of curves one of which passes through, or infinitely nearly through, every point of the area. Assign arbitrarily a particular value of ϕ to each of these curves; then graphically find $\frac{d\phi}{dv}$ and $\frac{d\phi}{dp}$ for any or every value of p and v . Then either of the two second forms of equation (12) gives us explicitly a value of t for any values whatever of p and v .

§ 49. The solution for t thus obtained involves the arbitrary assumption of a particular value of ϕ for each one of the series of curves which we have determinately traced. Hence, to render t wholly determinate, something more must be given than e as a function of p and v . Now the only thing that can be given respecting temperature for any particular substance before we have a thermometric scale is the relation subsisting between p and v when the temperature is constant. This relation can, with merely a single-temperature-thermoscope (§ 15 above), in addition to dynamical instruments, be determined for some one particular temperature; and this, if e be known for every value of p and v , is the only additional knowledge required for the determination of t for every value of p and v . For let $p=f(v)$ be the relation between p and v for some one particular temperature, t_0 . If by this we eliminate p from (12) we find

$$\frac{d\phi}{dv} = \frac{1}{t_0} \left[f(v) + \frac{dc}{dv} \right] \dots \dots (14);$$

where $\frac{dc}{dv}$, when $p=f(v)$, becomes a known function of v alone.

Hence by integration we find

$$\phi = \frac{1}{t_0} [F(v) + C] \dots \dots (15),$$

where F denotes a known function and C an arbitrary constant. Now trace the curve $p=f(v)$ on our diagram. It must generally cut every one of the previously drawn determinate series of curves. Hence equation (15), with two arbitrarily assigned constants t_0 and C , gives determinately the value of ϕ for every one of the diagram of curves, and thus ϕ is determined for every value of p and v . Either of equations (12) then gives t determinately as a function of p and v , with only the value t_0 arbitrary. The information from experiment, regarding the properties of the thermometric substance, on which this determination is founded, consists of a knowledge of the relation between p and v for any one temperature, and of the value of $e - e_0$ for all values of p, v , (e_0 denoting the unknown value of e for some particular values p_0, v_0). Although, theoretically, this information is attainable by purely dynamical operations and measurements, with no other thermal guidance or test than that afforded by a single-temperature-intrinsic-thermoscope (§ 15), the whole of it has not in fact been explicitly obtained for any one substance. But less than the whole of it suffices to make a perfect absolute thermometer of any given substance.

§ 50. For this purpose it is not necessary to find t for all values of p and v : it is enough to know it for all values mutually related in any manner convenient for thermometric practice. For example, if we could find t for every value of v with p constant at some one particular chosen value,—this would give a “constant pressure” absolute thermometer. Or again, if we find t for every value of p with v kept constant,—this would give us a “constant volume” absolute thermometer. Let us now examine into the restricted dynamic and thermoscopic investigations upon any particular substance, which will suffice to allow us to make of it a standard absolute thermometer of one or other of these species.

§ 51. *Dynamical and thermoscopic investigation required to graduate, according to the absolute scale, a constant-pressure thermometer of any particular fluid.*—Let a large quantity of fluid be given, and let proper mechanical means be taken to cause it to flow slowly and uniformly through a pipe, in one short length of which there is a fixed porous plug. If, as is the case with common air, nitrogen, oxygen, carbonic acid, and no doubt many other gases, the fluid leaves the plug cooler than it enters it, let there be a paddle in the stream flowing from the plug, and let this paddle be turned so as to stir the fluid and cause the temperature, when the

rapids are fairly past and the eddies due to the stirring subsided, to be the same as in the stream flowing towards the plug. When, as in the case of hydrogen and of all ordinary liquids, the fluid flows away from the plug warmer than it entered it, let a uniform stream of water be kept flowing in a separate canal outside the tube round a portion of it in which the internal flow is from the plug, and by this means let the temperature of the internal fluid be brought to equality with that which it had on entering the plug. By a separate thermodynamic experiment find how much work would have to be spent in stirring the external stream of water by a paddle to warm it as much as it is warmed by conduction from the internal fluid across the separating tube. Returning now to the internal fluid flowing towards and from the plug, let $p + \delta p$ be the pressure in the steady stream approaching the disturbed region, and p the pressure in the steady stream flowing from the disturbed region; and let δw be the quantity of work done by the paddle per unit of mass of the fluid passing by, reckoned positive in the first case, that namely in which the paddle compensates a cooling effect experienced in passing through the porous plug. In the second case $-\delta w$ (in this case a positive quantity) must denote the work done by the paddle upon the supposed external stream of water in the separate thermodynamic experiment. It is to be reckoned per unit mass of the internal fluid, irrespectively of the rate of flow of the external water. Let t denote the temperature of the fluid according to the thermodynamic scale, and let δt denote the infinitely small change of temperature which it must experience to produce an infinitesimal expansion from volume v to volume $v + \delta v$ under constant pressure. We have

$$\frac{v}{t} \frac{dt}{dv} = \frac{1}{1 + \frac{\delta w}{v}} \dots \dots (16).$$

Proof.—Let $v + \delta v, v$, and $e + \delta e, e$ be respectively the amounts of the volume and of the energy of the fluid per unit mass, in the tranquil stream before and after passing the disturbed region. The work done by an ideal piston pressing the fluid in towards the disturbed region is $(p + \delta p)(v + \delta e)$, and the work done by the emergent stream upon an ideal piston moving before it is pv , each reckoned per unit of mass, of the fluid. The whole work done on the fluid per unit mass by these ideal pistons is $p\delta v + v\delta p$; add to this δw done by the paddle, and we find that, on the whole, an amount of work equal to $p\delta v + v\delta p + \delta w$ is done on the fluid in passing through the disturbed region. Hence e exceeds $e + \delta e$ by this amount; that is to say,

$$-\delta e = p\delta v + v\delta p + \delta w \dots \dots (17).$$

Now the paddle and plug together act so as to render the temperatures equal in the tranquil streams at pressures p and $p + \delta p$. But if these were change of temperature its analytical expression would be

$$\delta t = \frac{dt}{dv} \delta v + \frac{dt}{dp} \delta p \dots \dots (18)$$

Hence δv and δp are so proportioned us to make this vanish. That is to say, we have

$$\delta v = - \frac{\frac{dt}{dp}}{\frac{dt}{dv}} \delta p \dots \dots (19)$$

and we have

$$\delta e = \frac{dc}{dv} \delta v + \frac{de}{dp} \delta p;$$

hence (17) divided by δp becomes

$$\frac{dc}{dv} \cdot \frac{\frac{dt}{dp}}{\frac{dt}{dv}} - \frac{dc}{dp} = p - \frac{dt}{dp} + v + \frac{\delta w}{\delta p} \dots \dots (20).$$

Using this in (11) we find

$$\frac{t}{dv} = n + \frac{\delta w}{\delta p} \dots \dots (21).$$

Dividing (21) by v , and taking the reciprocal of both members, we have the equation (16) which was to be proved.

§ 52. Now if for any particular fluid at some one given pressure p , with infinitesimal excess δp above this pressure for the higher pressure in the thermodynamic experiment, we find neither heating nor cooling effect in passing through the porous plug, the paddle has nothing to do; that is, $\delta w = 0$. If, with always the same pressure p , but with different values of v , that is to say, with the fluid given at different temperatures, but with pressures infinitely nearly the same, we always find the same result, $\delta w = 0$, it follows from (16) that for this particular fluid at the particular pressure of the experiment, and for all the temperatures of the experiment, we have

$$\frac{v}{t} \frac{dt}{dv} = 1 \dots \dots \dots (22).$$

Hence by integration

$$t = Cv \dots \dots \dots (23).$$

Hence we infer that with this fluid for thermometric substance, with the particular pressure of the experiment, and throughout the range of temperatures for which experiment has given us $\delta w = 0$, absolute temperature is shown on a scale graduated and numbered in simple proportion to the whole volume of the fluid.

§ 53. If the thermodynamic test repeated for the same fluid at different pressures gives still the same result, we have, for all pressures and temperatures within the range for which the supposed result $\delta w = 0$ has been found by the experiment,

$$t = f(p)v \dots \dots \dots (24);$$

where $f(p)$ denotes a quantity which depends only on the pressure of the fluid and is independent of its density.

§ 54. Joule and Thomson's experiments on the thermal effects of fluids in motion¹ showed that for pressures of from one to five or six atmos hydrogen gas, common air, nitrogen, oxygen, and carbonic acid, all somewhat approximately fulfil the condition of passing through the porous plug without change of temperature,—hydrogen much more approximately, carbonic acid much less approximately, than any of the others. Hence we infer that absolute temperature is somewhat approximately proportional to the volume of the fluid, if any one of these gases be used as the thermometric fluid in a constant-pressure thermometer. We shall presently see that the requisite correction of this statement for the case of hydrogen is so small as to be almost within the limits of accuracy of the most accurate thermometric usage.

§ 55. In the case of common air, nitrogen, oxygen, and carbonic acid, the experiments showed a slight cooling effect upon the fluid in passing through the porous plug; in the case of hydrogen, a much smaller heating effect. According to the rigorous dynamical form of our statement of § 51, we have no right to measure these heating and cooling effects on any scale of temperature, as we have not yet formed a thermometric scale. And it is interesting to remark that in point of fact the thermodynamic experiment described in that section involves the use of a differential thermoscope (§ 13) and not of any intrinsic thermoscope at all; and in respect to this requisite it may be contrasted with the thermodynamic investigation of § 49 previously, which involved the use, not of any continuous thermoscope, but only of a single-temperature intrinsic thermoscope (§ 14). Now, instead of reckoning on any thermometric scale the cooling effect or the heating effect of passage through the plug, we have to measure the quantity of work (δw) required to annul it, in the case of the majority of gases; and in the case of hydrogen, instead of reckoning on any thermometric scale the heating effect, we

have to measure — δw as explained in § 51. The experiments as actually made by Joule and Thomson simply gave the cooling effects and heating effects shown by mercury thermometers in the tranquil stream towards and from the plug; but the very thermometers that were used had been used by Joule in his original experiments determining the dynamical equivalent of heat, and again in his later experiments by which for the first time the specific heat of air at constant pressure was measured with sufficient accuracy for our present purpose. Hence by putting together different experiments which had actually been made with those thermometers of Joule's, the operation of measuring δw , at all events for the case of air, was virtually completed. Thus according to our present view the mercury thermometers are merely used as a step in aid of the measurement of δw , and their scales may be utterly arbitrary, provided we know the quantity of work required to raise unit mass of any of the fluids concerned through the particular differences of temperature actually shown by the thermometers in the Joule and Thomson experiment. The best way of doing this of course is to take advantage of the best measurements, that is to say Regnault's, of the thermal capacity of air at constant pressure, and then to calculate according to Joule's own measurement the dynamical equivalent of the heat required to warm water through one degree of his own thermometers.

§ 56. Let K be the thermal capacity, pressure constant, of the fluid experimented on, J the dynamical equivalent of the thermal unit, and δt the cooling effect (reckoned negative when the effect is rise of temperature), as measured by Joule's thermometers. We have

$$\delta w = JK\delta t \dots \dots \dots (25).$$

Hence (16) becomes

$$\frac{v}{t} \frac{dt}{dv} = \frac{1}{1 + \frac{JK}{v} \frac{\delta t}{\delta p}} \dots \dots \dots (26).$$

The experiment showed δt to be simply proportional to δp not merely for an infinitesimal difference of pressures but for pressures up to 5 or 6 atmos. For the case of hydrogen² the heating effect observed amounted, per 100 inches of mercury, to '100 of a degree centigrade at temperatures of 4° or 5° centigrade, and to '155 of a degree centigrade at temperatures of from 89° to 93° centigrade. The investigation was not carried out in sufficient detail to give any law of variation of this effect with temperature, and it was not even absolutely proved to be greater for the higher than for the lower temperature. In the circumstances we may take the mean of the results for the higher and lower temperatures, say '13 per 100 inches of mercury, or '039 per atmo. Hence if Π denotes the force per unit of area in the pressure called "one atmo," we have

$$\frac{\delta t}{\delta p} = - \frac{039}{\Pi},$$

$$\frac{v}{t} \frac{dt}{dv} = \frac{1}{1 - 039 \frac{JK}{\Pi v}} \dots \dots \dots (27)$$

Hence

$$\frac{dt}{t} = \frac{dv}{v - 039JK/\Pi},$$

which gives by integration

$$t = C(v - 039JK/\Pi) \dots \dots \dots (28).$$

The arbitrary constant C depends on the unit adopted for temperature. Let this be such that the difference of temperature between freezing and boiling is 100 (which will make our arbitrary scale agree with the ordinary centigrade scale in respect to the difference between these two temperatures). Denote now by t_0 the absolute temperature corresponding to 0° C. The absolute temperature corresponding to 100° C. will be $t_0 + 100$. Denote also by v_0 and v_{100} , for the same two temperatures, the bulks of unit mass of hydrogen at any constant pressure within the limits of Joule and Thomson's experiments, say, from one to five or six atmos. Then by dividing the value of each member of (28) for 0° C. by the difference of its values for 0° and 100°, we find

$$\frac{t_0}{100} = \frac{v_0 - 039JK/\Pi}{v_{100} - v_0} \dots \dots \dots (29).$$

Hence

$$t_0 = \frac{100}{E} (1 - 039JK/\Pi v_0) \dots \dots \dots (30);$$

¹ Transactions Royal Society, June 1853, June 1854, June 1860, and June 1862.

² Joule and Thomson, Transactions Royal Society, June 1860.

where E denotes the expansion of hydrogen, pressure constant, from 0° to 100° C in terms of its volume at 0°, that is to say,

$$E = \frac{v_{100} - v_0}{v_0} \dots \dots \dots (31).$$

Let V₀ denote what the volume would be at 0° C. if the pressure were Π instead of the actual pressure p. We have

$$t_0 = \frac{100}{E} \left(1 - \frac{V_0}{v_0} \cdot 0.039JK/\Pi V_0 \right) \dots \dots \dots (32).$$

Regnault finds (*Expériences*, vol. ii. p. 122) that the value of JK/ΠV₀ for hydrogen agrees within 1/2 per cent. with its value for common air; and for common air he finds K = .238. Thus with 423.5 for the value of J in metres (§ 9 above) we find JK = 100.79 metres. And Regnault's observations on the density of air give for ΠV₀ (or the height of the homogeneous atmosphere at 0° C.) 7990 metres. Hence for common air, and therefore also for hydrogen, JK/ΠV₀ = .0126; and thus (32) becomes

$$t_0 = \frac{100}{E} \left(1 + c \frac{V_0}{v_0} \right) \dots \dots \dots (33),$$

with c = -.0049 for hydrogen. For this gas expanding under constant pressure of one atmo Regnault found (*Expériences*, vol. i. p. 80) E = .36613, which gives $\frac{100}{E} = 273.13$. Hence (33), with v₀ = V₀, gives

$$t_0 = 273.00 \dots \dots \dots (34);$$

that is to say:—

§ 57. We conclude from Regnault's observations on the expansion of hydrogen from 0° to 100° C. under a constant pressure of one atmo, and from the small heating effect discovered in Joule and Thomson's experiments on the forcing of hydrogen through a porous plug, that the absolute temperature of melting ice is 273.00°, if the unit or degree of absolute temperature is so chosen as to make the difference one hundred between the temperatures of melting ice and of water with steam at one atmo of pressure.

§ 58. An almost identical number for that most important physical constant, the absolute temperature of melting ice, is obtained from observations on common air, and a not very different number from observations on carbonic acid, the only two gases besides hydrogen for which Regnault (*Expériences*, vol. i. p. 90) measured the expansion under constant pressure, and for which Joule and Thomson made their experiment on the thermal effect of passage through a porous plug. For each of these two gases the thermal effect observed was a lowering of temperature, and was found to vary at different temperatures very nearly in the inverse proportion of the square of the temperature C., by mercury thermometer, with 273 added. Hence nearly enough for use in the small term of the denominator of (26) we have, for air and carbonic acid,

$$\frac{\delta t}{\delta p} = A \left(\frac{273}{t} \right)^2 \frac{p}{\Pi} \dots \dots \dots (55),$$

where t denotes as before absolute temperature, and A the amount of the cooling effect per atmo of difference of pressures, on the two sides of the plug, at the temperature of melting ice. The values of A found for common air and carbonic acid are .275 and 1.388. Regnault (*Expériences*, vol. ii. p. 126) finds JK/ΠV₀ greater for carbonic acid than for common air in the ratio of 1.39 to 1 on the average of temperatures from 0° to 210°. But he found also that the specific heat of carbonic acid varies greatly with the temperature; and, taking the mean of the values which he finds for it at 0° and 100°, p. 130, as the proper mean for our present purpose, we find for JK/ΠV₀, a value 1.29 times its value for common air. From these experimental results we find by the mathematical process below (§ 61) still the same approximate formula (33), but with c = +.0026 for common air and c = +.0163 for carbonic acid. At constant pressure of one atmo Regnault's measurements gave E = .36706 for common air, and E = .3710 for carbonic acid; and dividing 100 by these decimals we find respectively 272.44 and 269.5. The corrections on these

numbers by formula (33) to give the absolute temperature of freezing are accordingly +.70 and +.44, and the corresponding estimates for the required absolute temperature are 273.14 and 273.9. Bringing together the results in the three cases, we see them conveniently in the following table:—

Name of Gas.	Expansion at one atmo according to Regnault. E.	Proper mean cooling-effect of forcing through porous plug per atmo according to Joule and Thomson. M.	Uncorrected estimate of absolute temperature of melting ice. $\frac{100}{E}$.	Correction calculated from cooling-effect. $\frac{100}{E} \times \frac{JK}{\Pi V_0}$.	Resulting estimate of absolute temperature of melting ice. t ₀ .
Hydrogen.....	.36613	-.039	273.13	-0°13	273.00
Air.....	.36706	+0°208	272.44	+0°70	273.14
Carbonic acid	.37100	+1°105	269.5	+4°4	273.9

1 Investigated in § 61 below.

The close agreement of the results from hydrogen and common air is very satisfactory, and it is interesting to see it brought about with so large a correction calculated from the Joule and Thomson effect. It is also interesting to see the sevenfold larger correction of nearly 5° bringing so nearly the same result from the 1 per cent. larger expansion of carbonic acid. The 1/2 per cent. discrepancy which remains between the results from carbonic acid and from hydrogen is not satisfactory, and requires explanation, particularly when we remark that, of five measurements by Regnault (*Expériences*, vol. i. p. 84) of the expansion of carbonic acid under constant pressure of one atmo, all lie within $\frac{1}{5.7}$ per cent. of the mean number .3710 which he has given, and we have taken, as his result.

Notwithstanding that the Joule and Thomson correction is so much greater for common air than for hydrogen, the result from common air is probably the most trustworthy of the three, because both Regnault's experiments and Joule and Thomson's were probably more accurate for air than for either of the other two gases. The true result to one place of decimals may therefore be considered as most probably being 273.1°, but the probability that it is nearer 273.1° than 273.0° is scarcely enough to make it worth while to use in any ordinary thermodynamic calculations any other number than 273°, which is exactly that found from hydrogen.

§ 59. The real meaning of our result 273.1° for the absolute temperature of melting ice, expressed without any choice of degrees or units for temperature, is that the ratio of the temperature at which vapour of water has a pressure of one atmo to the temperature at which ice melts is 373.1/273.1. Still another way of saying the same thing, this time eliminating all numerical reckoning of temperature, is (see THERMODYNAMICS) as follows:—

FOR EVERY HUNDRED UNITS OF HEAT CONVERTED INTO WORK BY A PERFECT THERMODYNAMIC ENGINE, 373.1 ARE TAKEN FROM THE SOURCE, AND 273.1 REJECTED TO THE REFRIGERATOR, IF THE TEMPERATURE OF THE SOURCE BE THAT AT WHICH STEAM OF WATER HAS A PRESSURE OF ONE ATM., AND THE TEMPERATURE OF THE REFRIGERATOR THAT AT WHICH ICE Melts.

§ 60. Integration of differential equation (26), § 56, between volume and absolute temperature for a gas, derived from the Joule and Thomson experiment.

Returning to § 56 we may write equation (26) as follows:—

$$\left(\frac{dv}{v} - v = JK \frac{\delta t}{\delta p} \right) \dots \dots \dots (36).$$

For each of the five gases experimented on, namely, common air, oxygen, nitrogen, carbonic acid, hydrogen, the experiment showed that, for all pressures up to five or six atmos, δt/δp was sensibly independent of the pressure, but that it varied very considerably with the temperature. Hence, if we put δt/δp = θ/Π, θ, which will

thus denote the cooling effect per atmo of differential pressure, is a function of the temperature, and is independent of the whole pressure. With this notation (36) becomes

$$t \frac{dv}{dt} - v = \frac{JK}{\Pi} \theta.$$

This is a linear equation in v with a second member, if for a moment we put $z = \log t$. Integrating it, and replacing t , we find, as the complete integral,

$$v = t \left\{ \frac{v_0}{t_0} + \frac{JK}{\Pi} \int_{t_0}^t \frac{\theta dt}{t^2} \right\} \dots \dots (37).$$

§ 61. Expansions of different gases, pressure constant, calculated from the Joule and Thomson experiment. We have from equation (37)

$$\frac{v - v_0}{v_0} = \frac{t - t_0}{t_0} \left\{ 1 + \frac{JK t_0}{\Pi v_0} \frac{1}{1 - \frac{t_0}{t}} \int_{t_0}^t \frac{\theta dt}{t^2} \right\} \dots \dots (38).$$

For each of the gases experimented on, except hydrogen, θ was found to vary nearly in the inverse ratio of t^2 . Putting then $\theta = A(t_0/t)^2$, we find

$$t_0 \int_{t_0}^t \frac{\theta dt}{t^2} = \frac{1}{2} A \left[1 - \left(\frac{t_0}{t} \right)^2 \right].$$

Hence, for these gases at pressures from 0 to 5 or 6 atmos, (38) becomes

$$\frac{v - v_0}{v_0} = \frac{t - t_0}{t_0} \left\{ 1 + \frac{1}{2} A \frac{JK}{\Pi v_0} \left[1 + \frac{t_0}{t} + \left(\frac{t_0}{t} \right)^2 \right] \right\} \dots \dots (39).$$

This shows that the "proper mean cooling effect" (M in the table of § 58) is

$$\frac{1}{2} \left[1 + \frac{t_0}{100 + t_0} + \left(\frac{t_0}{100 + t_0} \right)^2 \right] A,$$

$$= \frac{1}{2} \left(1 + \frac{1}{1.3663} + \frac{1}{1.3663^2} \right) A = .756A,$$

which differs so little from

$$\frac{1}{2} \left(1 + \frac{1}{1.3663^2} \right) A = .769A,$$

the arithmetic mean of the cooling effects at 0° and 100° C., that if we had simply taken the arithmetic mean for each of the other gases, as for want of knowing better we took it for hydrogen, the difference in the result would have been barely perceptible.

§ 62. Modifying (39) or (38) to suit any two temperatures, t, t' , we have

$$\frac{v - v'}{v'} = \frac{t - t'}{t'} \left(1 + \frac{JK}{\Pi v'} m \right) \dots \dots (40),$$

m denoting the proper mean cooling effect per atmo in the Joule and Thomson experiment (to be reckoned as negative in the case of hydrogen or any other gas, if there is any other, in which the experiment shows a heating effect). This "proper mean" may be taken as the arithmetic mean of the values for t and t' unless $t - t'$ considerably exceeds 100.

To reduce (40) to numbers, let V_0 be the volume of unit mass of the gas when at the temperature of melting ice, and under one atmo of pressure. Regnault (vol. ii. p. 303) finds that the value of K/V_0 is within 1 per cent. the same for oxygen, nitrogen, and hydrogen as for common air. He also (vol. ii. pp. 224-226) finds K to be the same for common air at from 1 to 12 atmos; for hydrogen, 1 to 9; for carbonic acid, 1 to 37.

No doubt similar constancy would be found for oxygen and nitrogen. Hence, as above (§ 56), for common air we still have $JK/\Pi V_0 = .0126$, and thus (40) becomes

$$\frac{v - v'}{v'} = \frac{t - t'}{t'} \left(1 + \frac{V_0}{v'} .0126m \right) \left\{ \begin{array}{l} \text{for common air,} \\ \text{oxygen,} \\ \text{hydrogen, and} \\ \text{nitrogen} \end{array} \right\} \dots \dots (41).$$

If in this formula we take t and t' for the temperatures of 100° C. and 0° C., $(v - v')/v'$ becomes $\frac{100}{273.1}$ or .3662; and we therefore find

$$E = .3662 \left(1 + \frac{V_0}{v_0} .0126m \right) \dots \dots (42),$$

which agrees with (33) above.

§ 63. The values given by Joule and Thomson's experiment for m are -0.039° for hydrogen, $+0.208^\circ$ for air, $+0.253^\circ$ for oxygen, and $+0.249^\circ$ for nitrogen.

From these and from the previous results for carbonic acid (§ 58) we have the following table for calculating the expansions from 0° C. to 100° C. of the gases named:—

Name of Gas.	Expansion under constant pressure (=E).
Hydrogen3662 (1 - 0.0049 $\frac{V_0}{v_0}$)
Common air3662 (1 + 0.0026 $\frac{V_0}{v_0}$)
Oxygen3662 (1 + 0.0032 $\frac{V_0}{v_0}$)
Nitrogen3662 (1 + 0.0031 $\frac{V_0}{v_0}$)
Carbonic acid3662 (1 + 0.0163 $\frac{V_0}{v_0}$)

(43).

These formulæ must be exceedingly near the truth for all pressures from 0 to 6 atmos, because within this range the thermal effects in the Joule and Thomson experiment were very approximately in simple proportion to the differences of pressure on the two sides of the plug. The following table of results calculated from (43) for several pressures of from 0 to 6 atmos is interesting as showing such different expansions for the different cases, determined by thermodynamic theory from Regnault's measurements of specific heats and Joule and Thomson's of their particular thermal effect, with absolutely no direct measurement of expansion except the one for common air at one atmo, shown as the third entry of column 5 in the table. The other five entries of column 5 show a fair amount of agreement between our theoretical results and the only direct measurements by Regnault. More of direct measurement, to allow a more extensive comparison, is very desirable.

Name of Gas.	Ratio of Bulk at 0° C. to Bulk supposing Pressure were 1 atmo at the same temperature.	Ratio of Density at 0° C. to Density supposing Pressure were 1 atmo at the same temperature.	Expansion, pressure constant, from 0° to 100° C.

§ 64. We are now quite prepared to make a practical working thermometer directly adapted to show temperature on the absolute thermodynamic scale through the whole range of temperature, from the lowest attainable by any means to the highest for which glass remains solid. It is to be remarked that our investigation of § 51, and all the deduced formulæ and relative calculations, are absolutely independent of the approximate fulfilment of Boyle's law by the gases to which we have applied them, and are equally applicable without any approach to fulfilment of Boyle's law; also that the only experimental data on which are founded our special numerical conclusions of §§ 59 to 63 are Regnault's measurements of specific heats under constant pressures, and Joule and Thomson's measurements of the thermal effect of forcing through a porous plug. From these experimental data alone we see by formula (38) of § 61 how to graduate a constant-pressure gas thermometer so that it shall show temperature on the absolute thermodynamic scale. Hence, notwithstanding the difficulty (§ 24 above) which Regnault found in the thermometric use of air or other gases on the system of constant pressure, and his practical preference for the constant-volume

air thermometer, it becomes of the highest importance to construct a practical constant-pressure gas thermometer. This we believe may be done by avoiding the objectionable expedient adopted by Pouillet and Regnault of allowing a portion (when high temperatures are to be measured the greater portion) of the whole gas to be pressed into a cool volumetric chamber out of the thermometric chamber proper by the expansion of the portion which remains in; and instead fulfilling the condition, stated, but pronounced practically impossible, by Regnault (*Expériences*, vol. i. pp. 168, 169), that the thermometric gas "shall, like the mercury of a mercury thermometer, be allowed to expand freely at constant pressure in a calibrated reservoir maintained throughout at one temperature."

We have accordingly designed a constant-pressure gas thermometer to fulfil this condition. It is represented in the accompanying drawing (fig. 10), and described in the following section.

§ 65. The vessel containing the thermometric fluid, which in this case is to be either hydrogen or nitrogen,¹ consists in the main of a glass bulb and tube placed vertically with bulb up and mouth down; but there is to be a secondary tube of much finer bore opening into the bulb or into the main tube near its top, as may be found most convenient in any particular case. The main tube which, to distinguish it from the secondary tube, will be called the volumetric tube, is to be of large bore, not less than 2 or 3 centimetres, and is to be ground internally to a truly cylindrical form. To allow this to be done it must be made of thick, well-annealed glass like that of the French glass-barrelled air-pumps. The secondary tube, which will be called the manometric capillary, is to be of round bore, not very fine, say from half a millimetre to a millimetre diameter. Its lower end is to be connected with a mercury manometer to show if the pressure of the thermometric air is either greater or less than the definite pressure to which it is to be brought every time a thermometric measurement is made by the instrument. The change of volume required to do this for every change of temperature is made and

FIG. 10.—Constant-Pressure Hydrogen Thermometer.

measured by means of a micrometer screw² lifting or lowering a long solid glass piston, fitting easily in the glass tube, and caulked air-tight by mercury between its lower end and an iron sole-plate by which the mouth of the volumetric tube is closed. To perform this mercury caulking, when the piston is raised and lowered, mercury is allowed to flow in and out through a hole in the iron sole-plate by an iron pipe, connected with two mercury cisterns at two different levels by branches each provided with a stopcock. When the piston is being raised the stopcock of the branch leading to the lower cistern is closed, and the other is opened enough to allow the mercury to flow up after the piston and press gently on its lower side, without entering more than infinitesimally into the space between it and the surrounding glass tube (the condition of the upper bounding surface of the mercury in this respect being easily seen by the observer looking at it through the glass tube). When the piston is being lowered the stopcock in the branch leading from the upper cistern is closed, and the one in the branch leading to the lower cistern is opened enough to let the mercury go down before the piston, instead of being forced to any sensible distance into the space between it and the surrounding tube, but not enough to allow it to part company with the lower surface of the piston. The manometer is simply a mercury barometer of the form commonly called a siphon barometer, with its lower end not open to the air but connected to the lower end of the manometric capillary. This connexion is made below the level of the mercury in the following manner. The lower end of the capillary widens into a small glass bell or stout tube of glass of about 2 centimetres bore and 2 centimetres depth, with its lip ground flat like the receiver of an air-pump. The lip or upper edge of the open cistern of the barometer (that is to say, the cistern which would be open to the atmosphere were it used as an ordinary barometer) is also ground flat, and the two lips are pressed together with a greased leather washer between them to obviate risk of breaking the glass, and to facilitate the making of the joint mercury tight. To keep this joint perennially good, and to make quite sure that no air shall ever leak in, in case of the interior pressure being at any time less than the external barometric pressure or being arranged to be so always, it is preserved and caulked by an external mercury-jacket not shown in the drawing. The mercury in the thus constituted lower reservoir of the manometer is above the level of the leather joint, and the space in the upper part of the reservoir over the surface of the mercury, up to a little distance into the capillary above, is occupied by a fixed oil or some other practically vapourless liquid. This oil or other liquid is introduced for the purpose of guarding against error in the reckoning of the whole bulk of the thermometric gas, on account of slight irregular changes in the capillary depression of the border of the mercury surface in the reservoir.

§ 66. In the most accurate use of the instrument, the glass and mercury and oil of the manometer are all kept at one definite temperature according to some convenient and

¹ Common air is inadmissible because even at ordinary temperatures its oxygen attacks mercury. The film of oxide thus formed would be very inconvenient at the surface of the mercury caulking, round the base of the piston, and on the inner surface of the glass tube, to which it would adhere. Besides sooner or later the whole quantity of oxygen in the air must be diminished to a sensible degree by the loss of the part of it which combines with the mercury. So far as we know, Regnault did not complain of this evil in his use of common air in his normal air thermometer (see §§ 24, 25 above), nor in his experiments on the expansion of air (*Expériences*, vol. i.), though probably it has vitiated his results to some sensible degree. But he found it to produce such great irregularities when, instead of common air, he experimented on pure oxygen that from the results he could draw no conclusion as to the expansion of this gas (*Expériences*, vol. i. p. 77). Another reason for the avoidance of air or other gas containing free oxygen is to save the oil or other liquid which is interposed between it and the mercury of the manometer from being thickened or otherwise altered by oxidation.

² This screw is to be so well fitted in the iron sole-plate as to be sufficiently mercury-tight without the aid of any soft material, under such moderate pressure as the greatest it will experience when the pressure chosen for the thermometric gas is not more than a few centimetres above the external atmospheric pressure. When the same plan of apparatus is used for investigation of the expansion of gases under high pressures, a greased leather washer may be used on the upper side of the sole in the screw-hole plate, to prevent mercury from escaping round the screw. It is to be remarked that in no case will a little oozing out of the mercury round the screw while it is being turned introduce any error at all into the thermometric result; because the correctness of the measurement of the volume of the gas depends simply on the mercury being brought up into contact with the bottom of the piston, and not more than just perceptibly up between the piston and volumetric tube surrounding it.

perfectly trustworthy intrinsic thermoscope (§§ 15 and 16 above), by means of thermal appliances not represented in the drawing but easily imagined. This condition being fulfilled, the one desired pressure of the thermometric gas is attained with exceedingly minute accuracy by working the micrometer screw up or down until the oil is brought precisely to a mark upon the manometric capillary.

In fact, if the glass and mercury and oil are all kept rigorously at one constant temperature, the only access for error is through irregular variations in the capillary depressions in the borders of the mercury surfaces. With so large a diameter as the 2 centimetres chosen in the figured dimensions of the drawing, the error from this cause can hardly amount to $\frac{1}{100}$ per cent. of the whole pressure, supposing this to be one atmo or thereabouts.

For ordinary uses of our constant-pressure gas thermometer; where the most minute accuracy is not needed, the rule will still be to bring the oil to a fixed mark on the manometric capillary; and no precaution in respect to temperature will be necessary except to secure that it is approximately uniform throughout the mercury and containing glass, from lower to higher level of the mercury. The quantity of oil is so small that, whatever its temperature may be, the bringing of its free surface to a fixed mark on the capillary secures that the mercury surface below the oil in the lower reservoir is very nearly at one constant point relatively to the glass, much more nearly so than it could be made by direct observation of the mercury surface, at all events without optical magnifying power. Now if the mercury surface be at a constant point of the glass, it is easily proved that the difference of pressures between the two mercury surfaces will be constant, notwithstanding considerable variations of the common temperature of the mercury and glass, provided a certain easy condition is fulfilled, through which the effect of the expansion of the glass is compensated by the expansion of the mercury. This condition is that the whole volume of the mercury shall bear to the volume in the cylindric vertical tube from the upper surface to the level of the lower surface the ratio $(\lambda - \frac{1}{2}\sigma)/(\lambda - \sigma)$, where λ denotes the cubic expansion of the mercury, and σ the cubic expansion of the solid for the same elevation of temperature, it being supposed for simplicity of statement that the tube is truly cylindric from the upper surface to the level of the lower surface, and that the sectional area of the tube is the same at the two mercury surfaces. The cubic expansion of mercury is approximately seven times the cubic expansion of glass. Hence

$$(\lambda - \frac{1}{2}\sigma)/(\lambda - \sigma) = (7 - \frac{1}{2})/6 = 1.111.$$

Hence the whole volume of the mercury is to be about 1.111 times the volume from its upper surface to the level of the lower surface; that is to say, the volume from the lower surface in the bend to the same level in the vertical branch is to be $\frac{1}{6}$ of the volume in the vertical tube above this surface. A special experiment on each tube is easily made to find the quantity of mercury that must be put in to cause the pressure to be absolutely constant when the surface in the lower reservoir is kept at a fixed point relatively to the glass, and when the temperature is varied through such moderate differences of temperature as are to be found in the use of the instrument at different times and seasons.

A sheet-iron can containing water or oil or fusible metal, with external thermal appliances of gas or charcoal furnace, or low-pressure or high-pressure steam heater, and with proper internal stirrer or stirrers, is fitted round the bulb and manometric tube to produce uniformly throughout the mass of the thermometric gas the temperature to be measured. This part of the apparatus, which will be called for brevity the heater, must not extend so far down the manometric tube that when raised to its highest tempera-

ture it can warm the caulking mercury to as high a temperature as 40° C., because at somewhat higher temperatures than this the pressure of vapour of mercury begins to be perceptible (see Table V. below), and would vitiate the thermometric use of the pure hydrogen or nitrogen of our thermometer. To secure sufficient coolness of the mercury it will probably be advisable to have an open glass jacket of cold water (not shown in the drawing) round the volumetric tube, 2 or 3 centimetres below the bottom of the heater, and reaching to about half a centimetre above the highest position of the bottom of the piston.

§ 67. It seems probable that the constant-pressure hydrogen or nitrogen gas thermometer which we have now described may give even more accurate thermometry than Regnault's constant-volume air thermometers (§ 24 above), and it seems certain that it will be much more easily used in practice.

We have only to remark here further that, if Boyle's law were rigorously fulfilled, thermometry by the two methods would be identical, provided the scale in each case be graduated or calculated so as to make the numerical reckoning of the temperature agree at two points,—for example, 0° C. and 100° C. The very close agreement which Regnault found among his different gas thermometers and his air thermometers with air of different densities (§ 25 above), and the close approach to rigorous fulfilment of Boyle's law which he and other experimenters have ascertained to be presented by air and other gases used in his thermometers, through the ranges of density, pressure, and temperature at which they were used in these thermometers, renders it certain that in reality the difference between Regnault's normal air thermometry and thermometry by our hydrogen gas constant-pressure thermometer must be exceedingly small. It is therefore satisfactory to know that for all practical purposes absolute temperature is to be obtained with very great accuracy from Regnault's thermometric system by simply adding 273 to his numbers for temperature on the centigrade scale. It is probable that at the temperatures of 250° or 300° C. (or 523 or 573 absolute) the greatest deviation of temperature thus reckoned from correct absolute temperature is not more than half a degree.

§ 68. The thermometric scale being now thoroughly established in theory and practice (§§ 33-69 and §§ 18-30), we are prepared to define, without any ambiguity, the expressions thermal capacity and specific heat with reference to matter at any temperature and in any physical condition.

Definition 1.—The thermal capacity of a body (whether it be a portion of matter homogeneous throughout or of homogeneous substance in two different conditions as liquid and steam, or solid and vapour of solid, or a piece of apparatus consisting of different parts as glass and metals, and containing as the case may be liquids or gases,—subject only to the condition that the whole matter considered is at one temperature) is the quantity of heat required to raise its temperature by one degree on the absolute thermodynamic scale.

Definition 2.—The specific heat of a substance is the thermal capacity of a stated quantity of it. This stated quantity is generally understood to be the unit of mass, unless some other definite quantity is explicitly designated, as for instance the quantity of the substance which occupies unit of volume at some definite pressure and temperature, for instance, one atmo and temperature 273 absolute. It is of no consequence what unit of mass is chosen provided it be the same as that which is used in defining the thermal unit; but, unless the contrary be explicitly stated, we always understand one gramme as the unit of mass and the thermal unit as the quantity of heat

required to raise one gramme of water from 273 to 274 (compare § 6 above).

§ 69. There is scarcely any subject upon which more skilled labour in scientific laboratories, chemical and physical, has been spent than the measurement of specific heats, whether of solids, liquids, or gases. An ample and well-arranged table of results is to be found in Clarke's *Constants of Nature*, a compilation of numerical results of scientific experiments made in all parts of the world by various observers and experimenters, a most valuable aid to scientific knowledge given to the world as No. 255 of the *Smithsonian Miscellaneous Collections*. It is most interesting as showing how very differently different substances behave in respect to constancy or variation of specific heat with temperature. Thus it shows that, according to the results of all the experimenters, the specific heats of all the substances experimented on, whether simple or compound, are very nearly constant at all events for ranges between -10° and 200° or 300° C., except the three elementary substances, boron, carbon, silicon. The specific heats of these three have been found by F. Weber to vary greatly with temperature. Thus for diamond he finds the specific heat to be $\cdot 1$ at 0° C. and $\cdot 27$ at 206° C., or nearly threefold of the amount at 0° ; at -50° C. the specific heat is $\cdot 063$; and at $+985^{\circ}$ it is $\cdot 459$ or about seven and a half times the specific heat at -50° (a curious practical commentary, we may remark in passing, on the doctrine of the calorists on specific heat referred to in § 8 above). The specific heats of carbon in its other forms of graphite and charcoal through wide ranges of temperature according to the same observer, F. Weber, are particularly interesting and significant. The approximate equality of the product of specific heat into the atomic weight for the simple metals is interesting and important; no less so is the utter want of constancy and uniformity in the corresponding product for other substances, whether simple or compound. If we were to define a metal as a substance for which through the range of temperature from 0° to 250° C. the product of the specific heat into the atomic weight is not less than $5\cdot 86$ and not greater than $6\cdot 93$, we should include every substance commonly called a metal, and no substance not commonly called a metal, except phosphorus, and solid sulphur lately fused.

Some important results of Regnault's regarding the specific heats of gases under constant pressure have been already quoted in §§ 56, 58, and 62 above. Further information from experiments aided by thermodynamic theory, regarding specific heats of gases and vapours under constant pressure and of gases in constant volume, will be found under the heading THERMODYNAMICS. To this also, and to the articles MATTER (PROPERTIES OF), LIQUID, and STEAM, the reader is referred for information respecting latent heats of liquofaction of solids and of evaporation of solids and liquids, also respecting the thermal capacity of a portion of homogeneous substance in two different states, such as the water-liquid and water-steam of an ordinary cryophorus or philosopher's hammer, or of the sulphurous acid liquid and steam of a sulphurous acid steam thermometer (§ 43 above).

TRANSFERENCE OF HEAT.

§ 70. When two contiguous portions of matter are at different temperatures, heat is transferred from the warmer to the colder. This process is called conduction of heat.

When two bodies at different temperatures are separated by a transparent medium, such as air, or water, or glass, or ice, heat passes from the warmer to the colder irrespectively of the temperature of the intervening medium, except in so far as its transparency may in some slight degree be affected by the temperature. Thus the colder of the two bodies be-

comes actually heated above the temperature of the intervening medium if the warmer be kept above this temperature, and if heat is not otherwise drawn off from the colder body in greater quantity than the heat entering it from the warmer. This process of transference from one body to another body at a distance through an intervening medium is called radiation of heat. The condition of the intervening matter in virtue of which heat is thus transferred is called light; and radiant heat is light if we could but see it with the eye, and not merely discern with the mind, as we do, that it is perfectly continuous in quality with the species of radiant heat which we see with the material eye through its affecting the retina with the sense of light. Thus a white hot poker in a room perfectly darkened from all other lights is seen as a brilliant white light gradually becoming reddish and less bright, until it absolutely fades from vision in a dull red glow. Long after it has ceased to be visible to the eye, the fact that heat is being transferred from it to colder bodies all round it, or above it or below it, is proved by our sense of heat in a hand or face held near it on any side or above it or below it. By considering the whole phenomenon of the white hot mass, without much of experimental investigation, we judge that there is perfect continuity through the whole process, in the first part of which the radiant heat is visible and in the second part invisible to the human eye: and thorough experimental investigation confirms this conclusion. Thus radiant heat is brought under the undulatory theory of light, which in its turn becomes annexed to heat as a magnificent outlying province of the kinetic theory of heat.

§ 71. In this article we confine ourselves to a practical evaluation of rate of gain or loss of heat across the surface of an isolated solid placed in a medium such as air, and enclosed in a solid surface all at one temperature, as is approximately the case with the air and the floor, walls, and ceiling of an ordinary room. A rough approximation to the law of this action, founded on supposing the rate of motion to be in simple proportion to the excess of the temperature of the isolated solid above the temperature of the surrounding medium and enclosure was used by Fourier in those of his solutions in which surface emissivity or, as he called it, "Conductibilité extérieure," is concerned. Without adopting any hypothesis, we define thermal emissivity as the quantity of heat per unit of time, per unit of surface, per degree of excess of temperature, which the isolated body loses in virtue of the combined effect of radiation and convection by currents of air. This definition does not involve the hypothesis of simple proportionality; and the surface emissivity is simply to be determined by experiment for any given temperature of the enclosure, and any given temperature of the isolated body. Dulong and Petit made elaborate experiments on this subject, but did not give any results in absolute measure.

So far as we know the first thoroughly trustworthy experiments giving emissivities in absolute measure were made in the laboratory of the natural philosophy class in the university of Glasgow by Mr D. Macfarlane, in a series of experiments on the cooling of a copper ball. The results are given in Table VII. The ball experimented on was 4 centimetres in diameter, and was suspended in the interior of a double-walled tin-plate vessel. The space between the double walls of this vessel was filled with water at the temperature of the air, and the interior surface was coated with lampblack. Two thermo-electric junctions, one at the centre of the ball the other in contact with the exterior surface of the enclosure, in circuit with a sensitive mirror galvanometer, served to measure the difference of temperatures between the centre of the ball and the exterior surface of the enclosure. By this arrangement the exterior junction was kept very uniformly at a tempera-

ture of 14° C., while the other had the varying temperature of the centre of the ball. Two sets of experiments were made. In one the ball had a bright surface, in the other it was coated with soot from the flame of a lamp, and in both the air was kept moist by a saucer of water placed in the interior of the tinplate enclosure. The results are given in terms of the number of units of heat lost per second, per square centimetre of surface of the copper, per degree of difference between the temperatures of the two junctions.

§ 72. Returning to the conduction of heat, we have first to say that the theory of it was discovered by Fourier and given to the world through the French Academy in his *Théorie Analytique de la Chaleur*,¹ with solutions of problems naturally arising from it, of which it is difficult to say whether their uniquely original quality, or their transcendently intense mathematical interest, or their perennially important instructiveness for physical science, is most to be praised. Here we can but give the very slightest sketch of the elementary law of conduction in an isotropic substance, the mathematical expression for it in terms of orthogonal plane or curved coordinates, and a few of the elementary solutions in Fourier's theory.

§ 73. Consider a slab of homogeneous solid bounded by two parallel planes. Let the substance be kept at two different temperatures over these parallel planes by suitable sources of heat and cold. For example, let one side be kept cold by a stream of cold water, or by a large quantity of ice and water in contact with it, and the other kept warm by a large quantity of warm water or by steam blown against it. Whatever particular plans of heater and refrigerator be adopted, care must be taken that the temperature be kept uniform over the whole, or over a sufficiently large area of each side of the slab, to render the isothermal surfaces sensibly parallel planes through the whole of the slab intercepted between the two calorimetric areas, and that the temperature at each side is prevented from varying with time. It will be found that heat must continually be applied at one side and removed from the other, to keep the circumstances in the constant condition thus defined. When this constant condition of surface temperature is maintained long enough, the temperature at every point of the slab settles towards a constant limiting value; and when this limiting value has been sensibly reached by every point of the slab, the temperature throughout remains sensibly constant so long as the surface temperatures are kept constant. In this condition of affairs the temperature varies continuously from one side of the slab to the other; and it is constant throughout each interior plane parallel to the sides; in other words, the isothermal surfaces are parallel planes. Let V and V' be the temperatures in two of these isothermals and a the distance between them. The quotient $\frac{V-V'}{a}$ is the average rate of variation of temperature per unit of length between these two isothermals.

Let Q be the quantity of heat taken in per unit of time at a certain area A on one side, and emitted at the corresponding area of the other side of the slab, measured by proper calorimetric appliances to these areas, which we shall call the calorimetric areas of the apparatus. It will generally be found that the value of the quotient $(V-V')/a$ is not the same for consecutive isothermal surfaces. For metals it is ascertained by experiment that it increases continuously from the cold side to the hot side of the slab. In other words, as we shall see presently, the thermal conductivity of the substance is not generally the same at different temperatures, and for metals it is smaller the higher the temperature.

¹ A translation into English by Freeman has been recently published, in 1 vol. 8vo, by the Cambridge University Press, 1879.

§ 74. Circumstances being as described in § 73, the thermal conductivity of the substance between the isothermals v and v' is the value of

$$\frac{Qa}{A(v-v')} \dots \dots \dots (14)$$

It must be remembered that the temperatures v , v' used in this definition are temperatures of the substance itself. Some experimenters have given largely erroneous results through assuming that the temperatures of the two sides of the slab were equal to those of the calorimetric fluids, such as warm water or steam on one side, and iced water or cold water, with its temperature measured by a thermometer, on the other side. To obtain correct results, the actual temperatures at two points in the conducting body itself must be ascertained by aid of suitable thermometers, or thermometers and differential thermoscopes, applied in such a way as not sensibly to disturb the isothermal surfaces. This, so far as we know, has not been done by any experimenter hitherto in attempting to measure thermal conductivity directly by the method indicated in the definition; and therefore if any results obtained by this method hitherto are trustworthy, it is only in a few cases,—cases in which, unless the substance experimented upon has been of such small conducting power, and the stirring of the calorimetric fluids on its two sides so energetic, that we can feel sure that the observed or assumed temperatures of these fluids, or of the portions of them of which the temperatures have been measured by thermometers, have not differed sensibly from the temperatures of the slab at its surfaces in contact with them.

§ 75. What utter confusion has permeated scientific literature, from experiments on thermal conductivity vitiated through non-fulfilment of this condition, is illustrated by results quoted in Everett's *Units and Physical Constants* (London, 1879), among which we find '19 for the conductivity of copper according to Pécelet, and 1'1 according to Ångström (which we now know to be correct). When we look to Pécelet's and Ångström's own papers the confusion becomes aggravated. Pécelet, in his *Mémoire sur la détermination des coefficients de conductibilité des métaux par la chaleur*,² quotes old experiments of Clément, and others more recent of Thomas and Laurent, regarding which he gives certain details. Taking his information no doubt from Pécelet's paper, Ångström gives a statement³ for the conductivity of copper, according to experimenters who had preceded him, which, with the decimal point shifted two places to the left to reduce to C. G. S., is as follows:—

Clément,	00231
Thomas and Laurent,	0122
Pécelet,	178

But Ångström did not notice that Pécelet had stated the thickness of the plate experimented on by Clément to be between 2 and 3 millimetres. Pécelet himself in his next sentence seems to have forgotten this when he compares the figure '23 which he had calculated from Clément's results, without taking account of the thickness of the plate, with 1'22 which he calculates from Thomas and Laurent's experiments on copper, without stating any thickness for the tube of copper on which (instead of a flat plate) they had experimented. Thus we have no data for finding what their results really were in either Pécelet's or Ångström's paper; but Pécelet seems to show enough regarding it to let us now feel perfectly sure that it is only a question of

² *Annales de Chimie et de Physique*, Paris, 1841.
³ In Ångström's own statement the unit quantity of heat is that required to raise 1000 grammes of water 1°. The conduction is reckoned per square metre of the copper plate per second of time, and the unit chosen for the rate of variation of temperature across the plate is 1° per millimetre. To reduce his numbers to the C. G. S. system we must therefore multiply by $10^3 \times 10^{-6} \times 10^{-1} = 10^{-4}$.

whether it is tens or hundreds of times too small. Omitting it then from the preceding statement, completing the correction by multiplying the .0023 by $2\frac{1}{2}$ (assuming the thickness of the plate to be $2\frac{1}{2}$ millimetres, as Péclet says it was between 2 and 3) to give Clément's result, and appending Ångström's result, which we now know to be correct, we have the following statement for thermal conductivity of copper in C. G. S. units:—

.0057,	according to Clément.
.178,	" " Péclet. ¹
.1,	" " Ångström.

§ 76. The comparison of these results is highly instructive. Clément's result is two hundred times too small, and Péclet's five times too small. Clément experimented by exposing one side of a plate of copper of a square metre surface and about two and a half millimetres thick to steam at 100° C., and the other side to water at 28° C. It was assumed that the difference of temperatures between the two sides was 72°. The difference really was about .36 of a degree, as we know from the quantity of heat actually conducted through it in Clément's experiment, indicated by the amount of steam which he found to be condensed into water. In fact, the amount of steam condensed did not differ sensibly from what it would have been if the copper plate had been infinitely thin, or its substance of infinite thermal conductivity. It is important in engineering, and in many of the arts and manufactures involving thermal processes, and particularly in that one of them of greater everyday value to the human race than all the others put together, cookery, to know that for copper or iron boilers, or steampipes, or pots or frying-pans, the transmission of heat from radiant burning coal or charcoal, or red or white hot fireclay or other solids, and from hot air in contact with them, on one side, to hot water or steam or oil or melted fat on the other side, or hot liquid or steam on one side and cool air on the other side, is for practical purposes sensibly the same as if the thermal conductivity of the metal were infinite, or its resistance to the transmission of heat nothing. The explanation is obvious to us now with the definite and sure knowledge regarding thermal conductivities of different substances and of matter in different conditions, solid, liquid, and gaseous, gained within the last twenty years. Ångström, Forbes, F. Neumann, and Tait have given, each one of them with thoroughly sufficient experimental evidence to leave no room to doubt the substantial accuracy of his results, absolute values for the thermal conductivities of copper and iron. Clausius and Maxwell have given us thermal conductivities of air and other gases, from their splendid development of the kinetic theory, which are undoubtedly trustworthy as somewhat close approximations to the true values, and which it is quite possible are more accurate than we can hope to see obtained from direct measurements of the conduction of heat through gases. J. T. Bottomley has given a trustworthy and somewhat closely accurate direct measurement of the thermal conductivity of water. From the results of these experimenters' work, reduced to uniform C. G. S. reckoning in our table of thermal conductivities (Table VIII.), we see that the thermal conductivity of iron is 80 times, and that of copper 500 times that of water. The thermal conductivity of iron is 3500 times, and that of copper is 20,000 times that of air. Hence, although the water or air at the very interface of its contact with the metal is essentially at the same temperature as the metal, there must be great differences of temperature in very thin layers of the fluid close to the interface when there is large flux of heat through the metal, and the temperature of the fluid as measured by any practicable thermometer, or

inferred from knowledge of the average temperature of the whole fluid, or from the temperatures of entering and leaving currents of fluid, may differ by scores of degrees from the actual temperature of the solid at the interface. It is remarkable that Péclet, while perceiving that Clément's result was largely erroneous on this account, and improving the mode of experimenting by introducing a rotating mechanical stirrer to change very rapidly the fluid in contact with the solid, only multiplied Clément's conductivity by 30 instead of by 200, which would have been necessary to annul the error. Notwithstanding his failure to obtain accurate results for metals, we have ventured to include his results for wood, and solids of lower conductivity than wood, in our table, because we perceive that he was alive to the necessity for very energetic stirring of the liquid, and the mechanical means which he adopted for it, though utterly insufficient for the case of even the least conductive of the metals, were probably not so for wood and solids of lower conductivity than wood; and because it is not probable that the complication of heat generated by the stirring (which Ångström suggests as an objection to Péclet's method) was in any case sufficient to produce a sensible influence upon the experimental results.

§ 77. The first correct determinations of thermal conductivities were given by Forbes in his paper on the temperature of the earth, in the *Transactions of the Royal Society of Edinburgh* for 1846, as calculated from his observations of underground temperature at three localities in the neighbourhood of Edinburgh—the trap rock of Calton Hill, the sand of the Experimental Garden, and the sandstone of Craighleith Quarry—by an imperfect approximate method indicated by Poisson. A more complete analytical treatment of the observational results, analysed harmonically and interpreted by application of Fourier's formula (equation (19) of Math. App.) to each term separately by W. Thomson, gave results (quoted in Table VIII. below) for the conductivities, which differed but little from Forbes's approximate determinations.

§ 78. It has always seemed to us that the best mode of experimenting on the conductivity of metals must, without doubt, be by an artificial imitation in a metallic bar, of the natural periodic variations of underground temperature, produced by periodically varied thermal appliances at one end of the bar. The effect of loss or gain of heat through the sides (or lateral surface) of the bar (ideally annullable by a coating of ideal varnish impermeable to heat) may be practically annulled by making the period of the variation small enough.

Let k be the thermal conductivity of the substance and c its thermal capacity per unit bulk. Let e be the emissivity (§ 71) of its surface. Let the bar be circular-cylindric, and r the radius of its cross section. At time t , let v be the mean temperature in a cross section at distance x from the end, and v' the surface temperature at the circular boundary of this section,—all temperatures being reckoned as differences from the temperature of the surrounding medium, called zero temporarily for brevity. The heat lost from the circumference of the bar between the cross sections $x - \frac{1}{2}dx$ and $x + \frac{1}{2}dx$ in time dt is $c v' \cdot 2\pi r dx dt$, and the heat conducted lengthwise, across the cross section x , in the same time, is $\pi r^2 \frac{dv}{dx}$. Hence we

readily find (see Math. App. below) as the equation of conduction of heat along the bar, very approximately if v' differs very little from v (that is to say, if the temperature is very nearly uniform throughout each cross section),

$$c \frac{dv}{dt} = \frac{d}{dx} \left(k \frac{dv}{dx} \right) - \frac{2e}{r} v' \dots \dots (1).$$

To estimate v' , let v'' be the temperature at the centre of the cross section x , and let $\left(\frac{-dv}{dr} \right)'$ denote the rate of decrease of temperature from within outwards in the substance of the bar close to its surface. We have clearly

$$v'' - v' < r \left(\frac{-dv}{dr} \right)';$$

¹ This result was published by Péclet in 1853, in a work entitled *Nouveaux documents relatifs au chauffage et à la ventilation*.

Estimating and comparing the annual periodic variations of temperature at the depths of the thermometers.

and, because the emission is supplied by conduction from within,

$$c v' = k \left(\frac{-dv'}{dr} \right)$$

Hence

$$v'' - v < \frac{c v'}{k}$$

The value of c for a blackened globe hung within a hollow, with blackened bounding surface, is about $\frac{1}{10000}$ according to Macfarlane's experiments (Table VII. below), and considerably less for surfaces with any degree of polish. We may therefore take $\frac{1}{10000}$ as a maximum value for c . The values of k for copper and iron at ordinary temperatures are, in C. G. S., approximately .95 and .18. Hence, if $r=5$ cms. (or the diameter of the bar 10 cms., which is more than it is likely to be in any laboratory experiments), we find

$$v'' - v < \frac{v'}{880} \text{ for copper,}$$

and

$$< \frac{v'}{100} \text{ for iron.}$$

Hence the error will be practically nothing if we take $v''=v$. Thus, and if we suppose k to be independent of temperature, (1) becomes

$$\frac{dv}{dt} = \frac{k}{c} \frac{d^2v}{dx^2} - \frac{2c}{rc} v \dots \dots \dots (2),$$

or

$$\frac{dv}{dt} = \kappa \frac{d^2v}{dx^2} - hv,$$

which is Fourier's equation for the conduction of heat along a bar or the circumference of a thin ring. Its solution to express simple harmonic variations of temperature produced in an infinitely long bar by properly varied thermal appliances at one end is

$$v = R e^{-\sigma \cos(\omega t - f x + e)} \dots \dots \dots (4),$$

n, R, e being arbitrary constants,—the "speed," the semi-range, and the epoch for $x=0$; and f, g constants given by the formulæ

$$f = \sqrt{\frac{1}{2\kappa} \left\{ (n^2 + h^2)^{\frac{1}{2}} - h \right\}} \dots \dots \dots (5),$$

$$g = \sqrt{\frac{1}{2\kappa} \left\{ (n^2 + h^2)^{\frac{1}{2}} + h \right\}}$$

For iron and copper the values of c are respectively .95 and .845. Hence, with the previously used values of k for these metals, and with $1/4000$ for e , we find $\kappa=1.1$ for copper and $\kappa=.2$ for iron; and for either, $h=1/1700r$ nearly enough.

Suppose, for example, $r=2$ cm., this makes $h=1/3400$; and suppose the period to be 32 m. (the greatest of those chosen by Ångström), this makes $n=2\pi/(60 \times 32)$, or roughly $n=1/310$ and $h/n=1/17$. Now when h/n is small, we have approximately

$$f = \sqrt{\frac{n}{2\kappa}} \cdot \left(1 - \frac{h}{2n} \right),$$

$$g = \sqrt{\frac{n}{2\kappa}} \cdot \left(1 + \frac{h}{2n} \right);$$

and therefore with the assumed numbers

$$f = \sqrt{\frac{n}{2\kappa}} \left(1 - \frac{1}{34} \right), \text{ and } g = \sqrt{\frac{n}{2\kappa}} \cdot \left(1 + \frac{1}{34} \right),$$

by which we see that the propagation of the variation of temperature is but little affected by the lateral surface emissivity. Little as this effect is, it is very perfectly eliminated by the relation

$$fg = 2 \frac{n}{\kappa} \dots \dots \dots (6),$$

which we find from (5).

It is convenient to remark that g is the rate of diminution of the Napierian logarithm of the range, and f the rate of retardation of the epoch (reckoned in radians) per centimetre of the bar. Were there no lateral emissivity these would be equal, and the diffusivity might be calculated from each separately. This was done by William Thomson in his analysis of the Edinburgh underground temperature observations. But in the propagation of periodic variation of temperature along a bar (as of electric potential along the conductor of a submarine cable) lateral emissivity (or imperfect insulation) augments the rate of diminution of the logarithm of the amplitude, and diminishes the rate of retardation of the phase, leaving the product of the two rates unaffected, and allowing the diffusivity to be calculated from it by (6). This was carried out for copper and iron by Ångström in Sweden, and the results communicated to the Royal Swedish Academy in January 1861. German and English editions

of his paper have been published in Poggendorff's *Annalen* for 1863; and the *Phil. Mag.* for 1863 (first half year). The details of the apparatus and of the actual experiments, in which Ångström had the assistance of Thalen, are sufficiently described in this paper,¹ and in a subsequent paper (Pogg. *Annalen* for 1863, p. 428), to allow us to feel perfect confidence in the very approximate accuracy of the results. Hence we have included them in our Table.

§ 79. The question, Does thermal conductivity vary with temperature? was experimentally investigated by Forbes about thirty years ago; and in a first provisional statement of results communicated to the British Association at Belfast in 1852 it was stated that the thermal conductivity of iron is less at high temperatures than at low. Forbes's investigation was conducted by an elaborate method of experimenting, in which the static temperature of a long bar of metal is observed after the example of the earlier experiments of Despretz, with a most important additional experiment and measurement by means of which the static result is reduced to give conductivity in absolute measure, and not merely as in Despretz's experiments to give comparisons between the conductivities of different metals. In 1861 and 1865 Forbes published results calculated from his experiments, including the first determination of thermal conductivity of a metal (iron) in absolute measure, and a confirmation of his old result that the conductivity of iron diminishes with rise of temperature. Forbes's bars have been inherited and further utilized, and bars of copper, lead, and other metals have been made and experimented upon according to the same method, by his successor in the university of Edinburgh, Professor Tait. The investigation was conducted partly with a view to test whether the electric conductivities and the thermal conductivities of different metals, more or less approximately pure, and of metallic alloys, are in the same order, and, further, if their thermal conductivities are approximately in the same proportion as their electric conductivities. The following results quoted from his paper on "Thermal and Electric Conductivity" (*Transactions R.S.E.*, 1878) are valuable as an important instalment, but expressly only an instalment, towards the answering of this interesting question:—

"Taking the inferior copper ('Copper C') as unit both for thermal and for electric conductivity, we find the following table of conductivities at ordinary temperatures, with the rough results as to specific gravity and specific heat referred to in § 15 above:—

	Thermal.	Electric.
Copper, Crown	1.41	1.729
" C.	1.00	1.000
Forbes's iron	0.29	0.264
Lead	0.12	0.149
German silver.....	0.14	0.117

¹ The first paper is marred unhappily by two or three algebraic and arithmetical errors. One algebraic error is very disturbing to a careful reader, and might even to a hasty judgment seem to throw doubt on the validity of the experimental use which is made of the formulæ. There is, however, no real foundation for any such doubt. The following little correction suffices to put the matter right. For the general term as printed in Ångström's paper read

$$e^{-2g_i \sqrt{i}} \sin \left(\frac{2i\pi t}{T} - \alpha g_i \sqrt{i} + \beta' \right),$$

with the following values for g_i, g'_i :—

$$g_i = \sqrt{\sqrt{\frac{\pi^2}{K^2 T^2} + \frac{H^2}{4K^2 i^2} + \frac{H}{2K i}}}$$

$$g'_i = \sqrt{\sqrt{\frac{\pi^2}{K^2 T^2} + \frac{H^2}{4K^2 i^2} - \frac{H}{2K i}}}$$

instead of these formulæ without the i , as Ångström gives them. Here we see that $g_i g'_i = \frac{\pi}{KT}$; and it is the product $g_i g'_i$ that Ångström uses in his experimental application, not the separate values of either g_i or g'_i . Hence no error is introduced by his having overlooked that g_i is not equal to g_1 except for $i=1$.

"The agreement of these numbers is by no means so close as is generally stated; but this is no longer remarkable, for it is well known that the electric conductivity of all pure metals alters very much with the temperature, while we have seen that as regards thermal conductivity there is but slight change with either copper or lead, though there is a large change with iron. This accords with some results of my own on the electric conductivity of iron at high temperatures (*Proc. R.S.E.*, 1872-73, p. 32), and with the results of the repetition of these experiments by a party of my laboratory students."—*Proc. R.S.E.*, 1875-76, p. 629.

§ 80. The absolute values of Tait's results for the five metals of the preceding list are given in C.G.S. units in our general table. As to change of conductivity with temperature there is a discrepancy between the results of Ångström's and Tait's experiments. Tait finds but little difference in the conductivity of copper through the wide range of temperatures from 0° to 300° C., and that difference an augmentation instead of a diminution at the high temperatures as shown in the following results (where t is measured from 0° C.):¹—

Copper, Crown	0.076 (1+0.0004 <i>t</i>)
" C.	0.054 (1+0.00055 <i>t</i>)
Iron	0.015 (1-0.00144 <i>t</i>)

On the other hand, Ångström finds for copper from experiments described in his second paper referred to above, at mean temperatures of from 28°·8 to 71°·5 C., results which reduced to C.G.S. are as follows:—

Copper.....	.982 (1 - .001519 <i>t</i>)
Iron.....	.199 (1 - .002874 <i>t</i>)

From the admirable method of experimenting, and the care with which experiments were carried out by himself and Thalen, it is impossible for us to doubt the validity and somewhat closely approximate numerical truth of the result. On account of the discrepancy from Tait's results it is desirable that Ångström's method should be carried out for copper through a much wider range of temperatures. This can be done with great ease from the lowest temperature obtainable by freezing mixtures to temperatures up to the melting point of copper, so excellently plastic is Ångström's method. Our proposed extension of it is to be carried out by proper thermal appliances to the end of the bar which Ångström left to itself,—appliances by which in one series of experiments it may be kept constant at -50° or -60° C., in others left to itself to take nearly the atmospheric temperature, in others kept at high temperatures limited only by the melting temperature of copper, if the experimenter desires to go so far. We would also suggest that the thermo-electric method first introduced by Wiedemann and Franz in their experiments on the static temperature of bars or wires heated at one end and allowed to lose heat by convection and radiation from their sides, (which was rejected, not, we think, judiciously, by Ångström), might be used with advantage instead of the mercury thermometers inserted in holes in the bar in Ångström's apparatus; or that, if thermometers are to be used, air thermometers in which the bulb of the thermometer is itself a very small hole in the bar experimented on, and the tube a fine-bore glass tube fitted to this hole, would be much preferable to the mercury thermometers hitherto employed in, we believe, all experiments except those of Wiedemann and Franz, on the conduction of heat along metallic bars.

§ 81. Fourier's ninth chapter is entitled "De la Diffusion de la Chaleur." The idea embodied in this title is the spreading of heat in a solid tending to ultimate equalization of temperature throughout it, instead of the transference of heat from one body to another by conduction through the

¹ These results are, like those given above in this section, expressed in terms of the foot and minute, but the unit of heat employed is the amount of heat required to raise the temperature of a cubic foot of the substance by 1°. In other words, these results are "diffusivities" (§ 82) in square feet per minute.

solid considered. Though Fourier makes the special subject of his chapter on "Diffusion" the conduction of heat through an infinite solid, we may conveniently regard as coming under the several designations "Diffusion of Heat" every case of thermal conduction in which the heat conducted across any part of the solid has the effect of warming contiguous parts on one side of it, or of leaving contiguous parts on the other side cooler,—in other words, every case in which the temperature of the body through which the conduction of heat takes place is varying with time, as distinguished from what Fourier calls "Uniform Motion of Heat," or the class of cases in which the temperature at every point of the body is constant. The experiments of Pécelet, Despretz, Forbes and Tait, Wiedemann and Franz, were founded on the uniform conduction of heat across slabs or along bores, and their determinations of relative and absolute conductivities were made by comparing or by measuring absolutely quantities of heat that were conducted out of the body tested. On the other hand, it is the diffusion of heat that is used in the determinations of thermal conductivity in absolute measure by Forbes and William Thomson from the periodic variations of under-ground temperature; in those of Ångström, from his experiments on the spreading of periodic variations of temperature through bars of iron and copper, and a series of valuable experiments a year or two later by F. Neumann, applying the same general method to bars of brass, zinc, German silver, and iron; in experiments by F. Neumann on substances of lower conductivity (coal, cast sulphur, ice, snow, frozen earth, gritstone) formed into cubes or globes of 5 or 6 inches diameter, and heated uniformly, and then left to cool in an atmosphere of lower temperature, and from time to time during the cooling explored by thermo-electric junctions imbedded in them to show their internal distribution; in similar experiments on the cooling of globes of 14 cm. diameter of porphyritic trachyte by Ayrton and Perry in Japan; and in Kirchof and Hansemann's recent experiments,² to find the thermal conductivity of iron by the not well-chosen method of suddenly cooling one side of a cube of iron of 14 cm., and observing the temperatures by aid of thermo-electric junctions in several points of the line perpendicular to this side through its middle.

By diffusion of heat.

§ 82. When the effect of heat conducted across any part of a body in heating the substance on one side or leaving the substance on the other side cooler is to be reckoned, it is convenient to measure the thermal conductivity in terms, not of the ordinary general grammo water-unit of heat, but of a special unit, the quantity required to raise unit bulk of the substance in 1°. In other words, if k be the conductivity in terms of any thermal unit, and c the thermal capacity of unit bulk of the substance, it is kc , not merely k , that expresses the quantity of the substance on which the phenomenon chiefly depends. We therefore propose to give to kc the name of thermal diffusivity (or simply diffusivity when heat is understood to be the subject), while still using the word thermal conductivity to denote the conducting power as defined in § 73, without restriction as to the thermal unit employed. It is interesting and important to remark that "diffusivity" is essentially to be reckoned in units of area per unit of time, that its "dimensions" are L^2D (see DIMENSIONS). Its regular C.G.S. reckoning is therefore in square centimetres per second. In the article DIFFUSION the relation between diffusion of heat and diffusion of matter is explained. We have added diffusion of electricity through a submarine cable, which has been shown³ to follow the same law as the

Thermal diffusivity.

² Wiedemann's (late Poggenorff's) *Annalen*, 1880, No. 1.

³ *Proc. Roy. Soc.*, May 1855, Wm. Thomson "On the Theory of the Electric Telegraph."

"linear" diffusion of heat, as Fourier calls the diffusion of heat when the isothermal surfaces are parallel planes. The curves of the following diagram and Tables A, B, and C show in a practically useful way the result in the course of the times noted, of from fractions of a second to thousands of millions of years, of linear diffusion of two different qualities in an infinite line from an initial condition in which there is sudden transition from one quality to the other, in the thoroughly practical cases specified in the accompanying explanations.

Equation of No. 2 is

$$v = \frac{\sigma}{2(\pi k t)} e^{-x^2/4kt}$$

proved in Math. App. xii. (27). Curve No. 1 is found by quadrature from (2) thus—

$$y = \text{const.} \times \int v dx.$$

FIG. 11.—Diagram of Diffusion.

Curve No. 1 shows temperature; or quantity of substance in solution; or potential in the conductor of a submarine cable through which electricity is diffusing. Curve No. 2 shows rate per unit of distance of variation of the temperature, or of the quantity of substance in solution. Vertical ordinates are actual distances through the medium. Horizontal ordinates represent temperature or quantity of diffusing substances in No. 1 curve, and rate of variation of temperature or of diffusing substance or of electric potential in No. 2 curve.

Diffusions.—Table A.

Substance.	Time in Seconds from the commencement of the Diffusion until the Condition represented by the Curves on the Actual Scale (b=2 Centimetres) is reached.
Carbonic acid through air	6.97 seconds.
Heat through hydrogen89 of a second.

TABLE III.—Expansions of Liquids.

Pierre, having measured the expansions of many different liquids, embodies the results in the empirical formula $\delta_t = at + bt^2 + ct^3$, where δ_t represents the expansion of unit volume from 0° to t° cent., and a, b, c have the values given in the Table for the different liquids specified. The substances and formulæ in quotation marks are quoted from Dixon's *Heat*, Dublin, 1849.

	Name of Liquid.	Atomic Constitution.	Temperature of Boiling Point.	Observed Pressure of Boiling Point.	Value of Coeff. a.	Value of Coeff. b.	Value of Coeff. c.

MATHEMATICAL APPENDIX.

Let v be the temperature at any point P specified by ξ, η, ζ according to any system of three sets of plane or curved orthogonal surfaces used for co-ordinates. Let $\lambda d\xi, \mu d\eta, \nu d\zeta$ be the lengths of the edges of the infinitesimal rectangular parallelepiped having P for its centre, and its sides parts of the six surfaces $\xi - \frac{1}{2}d\xi, \xi + \frac{1}{2}d\xi, \eta - \frac{1}{2}d\eta, \eta + \frac{1}{2}d\eta, \zeta - \frac{1}{2}d\zeta, \zeta + \frac{1}{2}d\zeta$.

The rates of variation of temperature per unit of length in the directions corresponding to the variations of ξ, η, ζ are respectively

$$-\frac{1}{\lambda} \frac{dv}{d\xi}, \quad -\frac{1}{\mu} \frac{dv}{d\eta}, \quad -\frac{1}{\nu} \frac{dv}{d\zeta}$$

Hence the fluxes across three infinitesimal rectangles having their edges parallel to the three pairs of sides of the parallelepiped, and each having its centre at P, are respectively

$$-\frac{k}{\lambda} \frac{dv}{d\xi} \cdot \mu \nu d\eta d\zeta, \quad -\frac{k}{\mu} \frac{dv}{d\eta} \cdot \nu \lambda d\xi d\zeta, \quad -\frac{k}{\nu} \frac{dv}{d\zeta} \cdot \lambda \mu d\xi d\eta$$

Hence the excess of the quantities of heat conducted in to the parallelepiped above those conducted out across the three pairs of faces is

$$\left\{ \frac{d}{d\xi} \left(k \frac{\mu \nu}{\lambda} \frac{dv}{d\xi} \right) + \frac{d}{d\eta} \left(k \frac{\nu \lambda}{\mu} \frac{dv}{d\eta} \right) + \frac{d}{d\zeta} \left(k \frac{\lambda \mu}{\nu} \frac{dv}{d\zeta} \right) \right\} d\xi d\eta d\zeta \dots (1)$$

The effect of this gain of heat is to warm the matter of the parallelepiped at a rate per unit of time equal to the rate of gain of heat divided by $c\lambda\mu\nu d\xi d\eta d\zeta$, the thermal capacity of the matter.

Hence

$$\frac{dv}{dt} = \frac{1}{c\lambda\mu\nu} \left\{ \frac{d}{d\xi} \left(k \frac{\mu \nu}{\lambda} \frac{dv}{d\xi} \right) + \frac{d}{d\eta} \left(k \frac{\nu \lambda}{\mu} \frac{dv}{d\eta} \right) + \frac{d}{d\zeta} \left(k \frac{\lambda \mu}{\nu} \frac{dv}{d\zeta} \right) \right\} \dots (2)$$

This, for the case of the uniform motion of heat ($dv/dt=0$), was first given by Lamé, to whom the generalized system of curvilinear coordinates for a point is due ("Mémoire sur les Lois de l'Équilibre des Fluides Étherés," *Journal de l'École Polytechnique*, vol. iii, cahier xxiii.). He deduced it from Fourier's equation [(3) below] in terms of plane rectangular coordinates by a laborious transformation. Equation (2) was first given, proved as above, as the direct expression of Fourier's fundamental law of conduction, by W. Thomson (*Cambridge Mathematical Journal*, Nov. 1843).

For plane rectangular coordinates we have $\lambda=\mu=\nu=1$ and if we put x, y, z for ξ, η, ζ in this case, (2) becomes

$$\frac{dv}{dt} = \frac{1}{c} \left\{ \frac{d}{dx} \left(k \frac{dv}{dx} \right) + \frac{d}{dy} \left(k \frac{dv}{dy} \right) + \frac{d}{dz} \left(k \frac{dv}{dz} \right) \right\} \quad (3)$$

which is Fourier's celebrated fundamental equation. From it we may deduce by transformation the proper forms of the corresponding equation for polar coordinates; but they are more easily got direct from the equation (2) for generalized coordinates. Thus for ordinary polar coordinates r, θ, ϕ we have, if we take these for ξ, η, ζ respectively,

$$\lambda=1, \quad \mu=r, \quad \nu=r \sin \theta.$$

Hence (2) becomes

$$\frac{dv}{dt} = \frac{1}{cr^2} \left\{ \frac{d}{dr} \left(kr^2 \frac{dv}{dr} \right) + \frac{1}{\sin \theta} \frac{d}{d\theta} \left(k \sin \theta \frac{dv}{d\theta} \right) + \frac{1}{\sin^2 \theta} \frac{d}{d\phi} \left(k \frac{dv}{d\phi} \right) \right\} \quad (4)$$

If k be constant, and we put $k/c = \kappa$, this becomes

$$\frac{dv}{dt} = \frac{\kappa}{r^2} \left\{ \frac{d}{dr} \left(r^2 \frac{dv}{dr} \right) + \frac{1}{\sin \theta} \frac{d}{d\theta} \left(\sin \theta \frac{dv}{d\theta} \right) + \frac{1}{\sin^2 \theta} \frac{d^2 v}{d\phi^2} \right\} \quad (5)$$

or

$$\frac{du}{dt} = \kappa \left\{ \frac{d^2 u}{dr^2} + \frac{1}{\sin \theta} \frac{d}{d\theta} \left(\sin \theta \frac{du}{d\theta} \right) + \frac{1}{\sin^2 \theta} \frac{d^2 u}{d\phi^2} \right\} \quad (6)$$

where $u = vr$

If again we take for the coordinates r, ϕ, z (polar coordinates in the plane perpendicular to z being denoted by r, ϕ), we have $\lambda=1, \mu=r, \nu=1$, and so find

$$\frac{dv}{dt} = \frac{1}{c} \left\{ \frac{d}{dr} \left(kr \frac{dv}{dr} \right) + \frac{d}{r d\phi} \left(k \frac{dv}{d\phi} \right) + \frac{d}{dz} \left(k \frac{dv}{dz} \right) \right\} \quad (7)$$

For the case of k constant we may take it outside the brackets in each of these equations, as we have already done in (4); thus (2) becomes

$$\frac{dv}{dt} = \frac{k}{c} \left(\frac{d^2 v}{dx^2} + \frac{d^2 v}{dy^2} + \frac{d^2 v}{dz^2} \right) \quad (8)$$

or, with κ for k/c , the diffusivity (§§ 81, 82),

$$\frac{dv}{dt} = \kappa \left(\frac{d^2 v}{dx^2} + \frac{d^2 v}{dy^2} + \frac{d^2 v}{dz^2} \right) \quad (9)$$

It is this restricted form which, with the further restriction that c be constant, is most generally recognized as Fourier's equation of conduction, and it is for it, with these restrictions, that his brilliant solutions were given. These solutions are available for practical use by limiting the range of temperature within which any one solution is continuously applied to a range of temperature within which the values of k and c are each nearly enough constant. We may expect 10° or 20° C. on each side of the mean temperature to be practically not too wide a range for any case, judging from copper and iron (§ 80), the only substances for which hitherto we have any information as to variations of both k and c with temperature.

Each of the following expressions I. . . XVII. for v satisfies (9) or its equivalent (6), as the reader will readily verify for himself. The special condition corresponding to the peculiar character of the particular solution is specially noted in each case.

I. Instantaneous simple point-source; a quantity θ of heat suddenly generated at the point (0, 0, 0) at time $t=0$, and left to diffuse through an infinite homogeneous solid.

EVERY OTHER SOLUTION IS OBTAINABLE FROM THIS BY SUMMATION.

$$v = \frac{Q e^{-r^2/4\kappa t}}{8\pi^{3/2}(\kappa t)^{3/2}} \quad (10)$$

where $r^2 = x^2 + y^2 + z^2$

where

Verify that $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} v dx dy dz = 4\pi \int_0^{\infty} v r^2 dr = Q$; and that $v=0$ when $t=0$; unless also $x=0, y=0, z=0$.

Remark that

$$\frac{dv}{dt} = 0 \text{ when } t = \frac{r^2}{6\kappa} \quad (11)$$

II. Constant simple point-source, rate q :

$$v \left[-q \int_{-\infty}^{\infty} dt \frac{e^{-r^2/4\kappa t}}{8\pi^{3/2}(\kappa t)^{3/2}} \right] = \frac{q}{4\pi r} \quad (12)$$

The formula within the brackets shows how this obvious solution is derivable from (11).

III. Continued point-source; rate per unit of time, at time t , an arbitrary function, $f(t)$:

$$v = \int_0^{\infty} d\chi f(t-\chi) \frac{e^{-r^2/4\kappa\chi}}{8\pi^{3/2}(\kappa\chi)^{3/2}} \quad (13)$$

IV. Time-periodic simple point-source, rate per unit of time at time t , $q \sin 2nt$.

$$v \left[q \int_0^{\infty} d\chi \sin 2n(t-\chi) \frac{e^{-r^2/4\kappa\chi}}{8\pi^{3/2}(\kappa\chi)^{3/2}} \right] = \frac{q}{4\pi r} e^{-(\kappa n)^{1/2} r} \sin \{2nt - (\kappa n)^{1/2} r\} \quad (14)$$

Verify that v satisfies (6); also that $-4\pi r^2 \frac{dv}{dr} = q \sin 2nt$ where $r=0$.

V. Instantaneous spherical surface source; a quantity Q suddenly generated over a spherical surface of radius a , and left to diffuse outwards and inwards:

$$v = Q \frac{e^{-(r-a)^2/4\kappa t} - e^{-(r+a)^2/4\kappa t}}{8\pi^{1/2}ar(\kappa t)^{1/2}} \quad (15)$$

To prove this most easily, verify that it satisfies (6); and farther verify that

$$4\pi \int_0^{\infty} v r^2 dr = Q;$$

and that $v=0$ when $t=0$, unless also $r=a$.

Remark that (15) becomes identical with (10) when $a=0$; remark farther that (15) is obtainable from (10) by integration over the spherical surface.

VI. Constant spherical surface source; rate per unit of time from the whole surface, q :

$$v \left[-q \int_0^{\infty} dt \frac{e^{-(r-a)^2/4\kappa t} - e^{-(r+a)^2/4\kappa t}}{8\pi^{1/2}ar(\kappa t)^{1/2}} \right] \left. \begin{array}{l} = q/4\pi r, \text{ where } r > a \\ = q/4\pi a, \text{ where } r < a \end{array} \right\} \quad (16)$$

The formula within the brackets shows how this obvious solution is derivable from (13).

VII. Time-periodic spherical surface source; rate per unit of time, at time t , from whole surface, $q \sin 2nt$:

$$v \left[-q \int_0^{\infty} d\chi \sin 2n(t-\chi) \frac{e^{-(r-a)^2/4\kappa\chi} - e^{-(r+a)^2/4\kappa\chi}}{8\pi^{1/2}ar(\kappa\chi)^{1/2}} \right] \left. \begin{array}{l} = \frac{A}{r} e^{-(\kappa n)^{1/2} r} \sin \{2nt - (\kappa n)^{1/2} r + B\}, \text{ where } r > a, \\ = \frac{C}{r} \left\{ e^{-(\kappa n)^{1/2} r} \sin \{2nt - (\kappa n)^{1/2} r + D\} - e^{(\kappa n)^{1/2} r} \sin \{2nt + (\kappa n)^{1/2} r + D\} \right\} \end{array} \right\} \quad (17)$$

where $r < a$

where A, B, C, D are constants determined by the conditions that

$$\text{and } -4\pi a^2 \left\{ \left(\frac{dv}{dr} \right)_{r>a} - \left(\frac{dv}{dr} \right)_{r<a} \right\} = q \sin 2nt,$$

when the two values of r exceed a and fall short of a by infinitely small differences. Verify that v satisfies (6). Also that v is finite when $r=0$.

VIII. Fourier's "Linear Motion of Heat"; instantaneous plane-source; quantity per unit surface, σ :

$$v = \frac{\sigma e^{-x^2/4\kappa t}}{2\pi^{1/2}(\kappa t)^{1/2}} \quad (18)$$

Verify that this satisfies (9) for the case of v independent of y and z , and that

$$\int_{-\infty}^{\infty} c d\kappa = \sigma$$

Remark that (18) is obtainable from (15) by putting $Q/4\pi a^2 = \sigma$, and $a = \infty$; or directly from (10) by integration over the plane.

IX. "Linear Motion of Heat"; time-periodic plane-source; rate per unit of area, per unit of time, at time t , $\sigma \sin 2nt$:

$$\left. \begin{aligned} v &= \left[-q \int_0^{\infty} d\chi \sin 2n(t - \chi) \frac{e^{-x^2/4\kappa\chi}}{2\pi^{1/2}(\kappa\chi)^{1/2}} \right] \\ &= \frac{\sigma}{(2n)^{1/2} 2\pi} e^{-n^2 t^2} \sin(2nt - n^2 t - \frac{1}{2}\pi) \text{ where } x > 0 \\ &= \frac{\sigma}{(2n)^{1/2} 2\pi} e^{+n^2 t^2} \sin(2nt + n^2 t - \frac{1}{2}\pi) \text{ where } x < 0 \end{aligned} \right\} \quad (19).$$

Verify that v satisfies $\frac{dv}{dt} = \kappa \frac{d^2v}{dx^2}$, which is what (9) becomes when v is independent of y and z ; also that

$$-2\pi \frac{dv}{dx} = \sigma \sin 2nt \text{ when } x \text{ is infinitely small positive,}$$

$$\text{and } +2\pi \frac{dv}{dx} = \sigma \sin 2nt \text{ when } x \text{ is infinitely small negative.}$$

X. "Linear Motion of Heat"; space-periodic simple harmonic solid source, with plane isothermal surfaces. Initial distribution, $v = V \sin ax$, when $t = 0$. Solution for any value of t

$$v \left[= V \int_{-\infty}^{\infty} d\xi \sin a(x - \xi) \frac{e^{-\xi^2/4\kappa t}}{2\pi^{1/2}(\kappa t)^{1/2}} \right] = V e^{-\kappa a^2 t} \sin ax \quad (20).$$

Modifying the integral within the brackets to make it appear as an analytical expression belonging to the general theory of images, for the case of a single infinite row of images, and equating the result to the right-hand member, we see that

$$\frac{1}{4\kappa t} \int_0^{2\pi/a} d\xi \frac{\sin a(x - \xi)}{\cos a(x - \xi)} \sum_{i=-\infty}^{i=\infty} e^{-\left(\xi + \frac{2i\pi}{a}\right)^2/4\kappa t} = e^{-\kappa a^2 t} \frac{\sin ax}{\cos ax} \quad (21),$$

i being any integer.

It is obvious that for a we may substitute ja in the second member, and in the factor $\frac{\sin a(x - \xi)}{\cos a(x - \xi)}$ under the integral sign of the first member, without altering it elsewhere, j being any integer: thus we have

$$\left. \begin{aligned} \frac{1}{4\kappa t} \int_0^{2\pi} d\xi \frac{\sin j a(x - \xi)}{\cos j a(x - \xi)} S &= e^{-\kappa j^2 a^2 t} \frac{\sin j a x}{\cos j a x} \\ \text{where } S &= \sum_{i=-\infty}^{i=\infty} e^{-\left(\xi + \frac{2i\pi}{a}\right)^2/4\kappa t} \end{aligned} \right\} \quad (22).$$

XI. "Linear Motion of Heat"; space-periodic arbitrary solid source, isothermals plane. Initial distribution, $v = f(x)$, when $t = 0$, f denoting an arbitrary periodic function, period l ; so that $f(x + il) = f(x)$, i being any integer. Two solutions (A), (B).

(A) derived synthetically from (10):

$$v = \frac{1}{2(\pi\kappa t)^{1/2}} \int_0^l d\xi f(x - \xi) S \quad (23),$$

$$\text{where } S = \sum_{i=-\infty}^{i=\infty} e^{-\left(\xi + il\right)^2/4\kappa t} \quad (24);$$

(B) derived analytically and synthetically from (20).

Find $A_0, A_1, A_2, \dots, B_1, B_2, \&c.$, by the harmonic analysis, to satisfy the condition

$$\left. \begin{aligned} jx &= A_0 + A_1 \cos \theta + A_2 \cos 2\theta + \&c. \\ &+ B_1 \sin \theta + B_2 \sin 2\theta + \&c. \end{aligned} \right\} \quad (25).$$

$$\text{where } \theta = \frac{2\pi x}{l}$$

$$\text{Then } v = A_0 + \sum_{j=1}^{j=\infty} e^{-\kappa \left(\frac{2j\pi}{l}\right)^2 t} \left(A_j \cos \frac{2j\pi x}{l} + B_j \sin \frac{2j\pi x}{l} \right) \quad (26).$$

XII. Uniform row of simple instantaneous plane sources. Two solutions (A) and (B).

(A), from XI. (A), (23):

$$v = \frac{\sigma}{2(\pi\kappa t)^{1/2}} \sum_{i=-\infty}^{i=\infty} e^{-\left(x + il\right)^2/4\kappa t} \quad (27).$$

The No. 2 diffusion curve of § 82 is the representation of the first term ($i = 0$) of this formula.

(B), from XI. (B), (25) and (26):

$$v = \frac{\sigma}{l} \left\{ 1 + 2 \sum_{j=1}^{j=\infty} e^{-\kappa \left(\frac{2j\pi}{l}\right)^2 t} \cos \frac{2j\pi x}{l} \right\} \quad (28).$$

The comparison of these two solutions is very interesting physi-

cally, and useful arithmetically. To facilitate the comparison, put

$$i/2(\pi\kappa t)^{1/2} = q, \text{ and } x/2(\pi\kappa t)^{1/2} = p \quad (29);$$

the two solutions become

$$\frac{dv}{\sigma} = q \sum_{i=-\infty}^{i=\infty} e^{-\pi(p+iq)^2} = 1 + 2 \sum_{j=1}^{j=\infty} e^{-\frac{j^2\pi}{q^2}} \cos \frac{2j\pi p}{q} \quad (30).$$

The equation between the second and third member, virtually due originally to Fourier, is also an interesting formula of Jacobi's, *Fundamenta Nova Theoriae Functionum Ellipticarum*, as was long ago pointed out by Cayley.² Each formula is a series which converges for every value of l however small or however great; the first, (27), the more rapidly the less is l ; the second, (28), the more rapidly the greater is l . For the case of $l = l^2/4\kappa\pi$, and $x = 0$ (that is, $q = 1$ and $p = 0$), the two series become identical. For the more comprehensive case of $p = 0$, but q unrestricted, the comparison gives the following very curious arithmetical theorem—

$$q \frac{1 + 2(\epsilon^{-\pi q^2} + \epsilon^{-4\pi q^2} + \epsilon^{-9\pi q^2} + \&c.)}{1 + 2(\epsilon^{-\pi/q^2} + \epsilon^{-4\pi/q^2} + \epsilon^{-9\pi/q^2} + \&c.)} = 1 \quad (31).$$

When $l \geq l^2/4\kappa\pi$ (or $q \geq 1$) the first solution (27) converges with so great suddenness that three terms suffice for most practical purposes; when $l \leq l^2/4\kappa\pi$ (or $q \leq 1$) the second solution (28) converges with so great suddenness that one term (after the constant first term) suffices for most practical purposes. Thus by using the solution (27) for all values of l from zero to something less than $l^2/4\kappa\pi$, and (28) for all values greater than the greatest for which (27) is used, we have an exceedingly rapid convergence and easy calculation to find v for any values of x and t . These formulae, thus used, have been of great practical value in calculating what is now known as the arrival curve of signals through a submarine cable, and in designing instruments to record it automatically and allow its telegraphic meaning to be read, or without recording it to allow its meaning to be read by watching the motions of a spot of light. It is clear that (27) and (28) express the potential at a point at distance x from one end of a cable of length l , at time t from an instant when a quantity $\frac{1}{2}oc$ of electricity has been suddenly communicated to that end of the cable, both ends being always kept insulated after that instant (as is done practically by an exceedingly short contact with one pole of a voltaic battery, the other being kept to earth). The value of v for $x = \frac{1}{2}l$, and for all values of t from 0 to ∞ , represents the rise of the potential at the remote end towards the limiting value $\frac{\sigma}{\epsilon}$, towards which the potential rises throughout the conductor.

XIII. (X. in three dimensions.) Space triple periodic solid source; in other words $v = V \sin ax \sin by \sin cz$, when $t = 0$. Solution for any value of t —

$$\left. \begin{aligned} v &= \left[-V \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} d\xi d\eta d\zeta \sin a(x - \xi) \sin b(y - \eta) \sin c(z - \zeta) \frac{e^{-\xi^2 + \eta^2 + \zeta^2}}{8\pi^{3/2}(\kappa t)^{3/2}} \right] \\ &= V \sin ax \sin by \sin cz e^{-\kappa(a^2 + b^2 + c^2)t} \end{aligned} \right\} \quad (32).$$

Remark that, as an analytical expression for the present case of the general theory of triply-multiple images, the triple integral within the brackets may be written

$$\left. \begin{aligned} V \int_0^{2\pi/a} \int_0^{2\pi/b} \int_0^{2\pi/c} d\xi d\eta d\zeta \sin a(x - \xi) \sin b(y - \eta) \sin c(z - \zeta) \frac{S}{8\pi^{3/2}(\kappa t)^{3/2}}, \\ \text{where } S = \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \sum_{k=-\infty}^{\infty} e^{-\frac{\left(\xi + \frac{2i\pi}{a}\right)^2 + \left(\eta + \frac{2j\pi}{b}\right)^2 + \left(\zeta + \frac{2k\pi}{c}\right)^2}{4\kappa t}} \end{aligned} \right\} \quad (33),$$

i, j, k , being any positive or negative integers.

XIV. and XV. (X. and XI. in three dimensions. The formulae may be written down by inspection; from I., with X. and XI. for guides. The analytical theorem thus obtained, corresponding to (30); in three dimensions, is interesting to pure mathematicians.

XVI. Harmonic solutions. Any distribution of heat, whether in an infinite or in a bounded solid, which keeps its type unchanged in subsiding towards uniformity, when left without positive or negative sources, except such, essentially negative, as are required to fulfil a proper boundary condition, is called a harmonic distribution, provided the temperature does not increase to infinity in any direction. The boundary condition, if the solid is bounded, is essentially that the rate of emission from the surface at every point of it varies in simple proportion to the temperature, and at such a rate per l^2 of temperature at each part of the surface as the solution requires. X. and XIII. are examples. The general condition for a harmonic solution is

$$v = f(t)F(x, y, z) \quad (34);$$

² Quarterly Journal of Mathematics for 1857; Note by Cayley on an article by W. Thomson, entitled "On the Calculation of Transcendents of the form $\int_0^x e^{-x^2} f(x) dx$."

¹ This is Fourier's (c) of Art. 374 for the case of $f(x)$ a periodic function.

and this tried in (9) gives

$$\frac{1}{f(t)} \frac{df(t)}{dt} = \kappa \frac{\frac{d^2F}{dx^2} + \frac{d^2F}{dy^2} + \frac{d^2F}{dz^2}}{F} \quad (35).$$

The first member being independent of x, y, z , and the second being independent of t , the common value of the two must be independent of x, y, z, t , that is to say, must be an absolute constant. Let it be denoted by $-\epsilon$; we have

$$f(t) = C\epsilon^{-\rho t} \quad (36),$$

$$\text{and } \frac{d^2F}{dx^2} + \frac{d^2F}{dy^2} + \frac{d^2F}{dz^2} + \frac{\rho}{\kappa} F = 0 \quad (37),$$

or in terms of polar coordinates, by (6),

$$\left. \begin{aligned} \frac{d^2U}{dr^2} + \frac{1}{r^2} \frac{d}{d\theta} \left(\sin\theta \frac{dU}{d\theta} \right) + \frac{1}{r^2 \sin^2\theta} \frac{d^2U}{d\phi^2} + \frac{\rho}{\kappa} U = 0 \end{aligned} \right\} (38).$$

where $U = \frac{F}{r}$.

Of this we have a spherical harmonic solution,

$$U = [A\phi_i(r) + B\psi_i(r)]S_i \quad (39),$$

where S_i denotes a spherical surface-harmonic of order i , and $\phi_i(r), \psi_i(r)$, two particular solutions of the equation

$$\frac{d^2u}{dr^2} + \left[\frac{\rho}{\kappa} - \frac{i(i+1)}{r^2} \right] u = 0 \quad (40).$$

Then (36) and (35) give finally

$$v = \epsilon^{-\rho t} \frac{A\phi_i(r) + B\psi_i(r)}{r} S_i \quad (41).$$

This solution is in its generality applicable to an infinite solid occupying all space except a hollow round the origin. The solid may of course be bounded externally also by a finite closed surface. If there be no hollow, A/B must fulfil the condition that $[A\phi_i(r) + B\psi_i(r)]/r$ is finite when $r=0$. If there are two boundaries, concentric spherical surfaces, with their common centre at the origin of coordinates, the boundary condition obviously requires uniform emissivity over each, but not necessarily equal for the two. If the two emissivities be denoted by h and h' , and the radii of the surfaces by a (outer) and a' (inner), the boundary conditions are

$$\left. \begin{aligned} \frac{dv}{dr} &= -hv, \text{ when } r=a \\ \text{and } \frac{dv}{dr} &= h'v, \text{ when } r=a' \end{aligned} \right\} \quad (42).$$

From these we may find h and h' , so as to let the harmonic character of the solution be fulfilled in the subsidence. Or if h and h' be given, we have in (41) two equations which determine the two unknown quantities A/B and ρ . Eliminating A/B, we thus find a single transcendental equation for ρ , which is proved to have no imaginary or negative roots, and an infinite number of real positive roots, each $> \kappa i(i+1)/r^2$. In the case of $i=0$, or temperature independent of ϕ and θ , (40) gives

$$u = A \cos r \sqrt{\frac{\rho}{\kappa}} + B \sin r \sqrt{\frac{\rho}{\kappa}}.$$

For this case the transcendental equation for determining values for ρ is very simple, and its roots are calculated numerically with great ease. With the further restriction of no central hollow, we must have $A=0$, so that u/r may be finite when $r=0$. This case was fully investigated by Fourier, and very beautifully worked out in his fifth chapter. The more general problem of a solid sphere, with any given initial distribution of temperature, without the restriction of temperature independent of θ and ϕ , was solved first we believe by Poisson in the 11th chapter of his *Théorie Mathématique de la Chaleur*, in terms of the formulæ (36), (38), (40) above.

XVII. The equation of the transference of heat in terms of columnar coordinates, (7) above, affords naturally another beautiful case of harmonic solution. Assume

$$v = \epsilon^{-\rho t} u_i \frac{\sin u_i}{\cos u_i} i\phi \frac{\sin m z}{\cos m z} \quad (43);$$

we find by (7)

$$\frac{d^2u_i}{dr^2} + \frac{1}{r} \frac{du_i}{dr} + \left(\frac{\rho}{\kappa} - m^2 - \frac{i^2}{r^2} \right) u_i = 0 \quad (44).$$

The treatment of this equation and its integral (obviously derivable by i differentiations from u_0 , which is a Bessel's function) for the full solution of the thermal problem is most interesting, and very instructive and suggestive in respect to pure analysis. It was splendidly worked out for the case of $m=0$ and $i=0$ by Fourier in his 6th chapter. "The Motion of Heat in a Solid Cylinder," truly a masterpiece of art. When it was printed in 1821, and published after having with the rest of Fourier's work been buried alive for fourteen years in the archives of the French Academy, and when Bessel found in it so thorough an investigation and so strikingly beautiful an application of the "Besselsche Function," we can imagine the ordinary feeling towards those "qui ante nos nostra dixerunt" reversed into the pleasure of genuine admiration.

HEATH, the English form of a name given in most Teutonic dialects to the common ling or heather, but now applied to all species of *Erica*, an extensive genus of monopetalous plants, belonging to the order *Ericaceæ*. The heaths are evergreen shrubs, with small narrow leaves, in whorls usually set rather thickly on the shoots; the persistent flowers have 4 sepals, and a 4-cleft campanulate or tubular corolla, in many species more or less ventricose or inflated; the dry capsule is 4-celled, and opens, in the true *Erica*, in 4 segments, to the middle of which the partitions adhere, though in the ling the valves separate at the dissepiments. The plants are mostly of low growth, but several African kinds reach the size of large bushes, and a Spanish variety, *E. arborea*, occasionally attains almost the aspect and dimensions of a tree.

One of the best known and most interesting of the family is the common heath, heather, or ling, *Calluna vulgaris*, placed by most botanists in a separate genus on account of the peculiar dehiscence of the fruit, and from the coloured calyx, which extends beyond the corolla, having a whorl of sepal-like bracts beneath. This shrub derives some economic importance from its forming the chief vegetation on many of those extensive wastes that occupy so large a portion of the more sterile lands of northern and western Europe, the usually desolate appearance of which is enlivened in the latter part of summer by its abundant pink blossoms. When growing erect to the height of a yard or more, as it often does in sheltered places, its purple stems, close-leaved green shoots, and feathery spikes of bell-shaped flowers render it one of the handsomest of the heaths; but on the bleaker elevations and more arid slopes it frequently rises only a few inches above the ground. In

all moorland countries the ling is applied to many rural purposes; the larger stems are made into brooms, the shorter tied up into bundles that serve as brushes, while the long trailing shoots are woven into baskets. Pared up

FIG. 1.—*Erica cinerea*.

FIG. 2.—*Calluna vulgaris*.

with the peat about its roots it forms a good fuel, often the only one obtainable on the drier moors. The shielings of the Scotch Highlanders were formerly constructed of heath stems, cemented together with peat mud, worked into a

kind of mortar with dry grass or straw; hovels and sheds for temporary purposes are still sometimes built in a similar way, and roofed in with ling. Laid on the ground, with the flowers above, it forms a soft springy bed, the luxurious couch of the ancient Gael, still gladly resorted to at times by the hill shepherd or hardy deer-stalker. The young shoots were in former days employed as a substitute for hops in brewing, while their astringency rendered them valuable as a tanning material in Ireland and the Western Isles. They are said also to have been used by the Highlanders for dyeing woollen yarn yellow, and other colours, are asserted to have been obtained from them, but some writers appear to confuse the dyer's-weed, *Genista tinctoria*, with the heather. The young juicy shoots and the seeds, which remain long in the capsules, furnish the red grouse of Scotland with the larger portion of its sustenance; the ripe seeds are eaten by many birds. The tops of the ling afford a considerable part of the winter fodder of the hill flocks, and are popularly supposed to communicate the fine flavour to Welsh and Highland mutton, but sheep seldom crop heather while the mountain grasses and rushes are sweet and accessible. In recent times ling has been suggested as a material for paper, but the stems are hardly sufficiently fibrous for that purpose. The purple or fine-leaved heath, *E. cinerea*, one of the most beautiful of the genus, abounds on the lower moors and commons of Great Britain and western Europe, in such situations being sometimes more prevalent than the ling. The flowers of both these species yield much honey, furnishing a plentiful supply to the bees in moorland districts; from this heath honey the Picts probably brewed the mead said by Boetius to have been made from the flowers themselves.

It was until recently supposed that no species of heath existed in America; but of late years isolated plants of ling have been found in various parts of New England, Nova Scotia, and Cape Breton, while it has been stated to occur in some abundance in several places in Newfoundland; probably in distant ages it may have had a wider range on the American continent. The whole group, as observed by Bentham, is "eminently Atlantic" in its present distribution,—of nearly 500 known species by far the greater part being indigenous to the western districts of South Africa, and nearly all the remainder limited to Europe and its adjacent islands.

The Cape heaths have long been favourite objects of horticulture. In the warmer parts of Britain several will bear exposure to the cold of ordinary winters in a sheltered border, but most need the protection of the conservatory. They are sometimes raised from seed, but are chiefly multiplied by cuttings "struck" in sand, and afterwards transferred to pots filled with a mixture of black peat and sand; the peat should be dry and free from sourness. Much attention is requisite in watering heaths, as they seldom recover if once allowed to droop, while they will not bear much water about their roots: the heath-house should be light and well ventilated, the plants requiring sun, and soon perishing in a close or permanently damp atmosphere; in England little or no heat is needed in ordinary seasons. The European heaths succeed well in English gardens, only requiring a peaty soil and sunny situation to thrive as well as in their native localities: *E. carnea*, *mediterranea*, *ciliaris*, *vagans*, and the pretty cross-leaved heath of boggy moors, *E. tetralix*, are among those most worthy of cultivation. The beautiful large-flowered St Dabeoc's heath, belonging to the closely allied genus *Menziesia*, is likewise often seen in gardens.

(C. P. J.)

HEATHCOAT, JOHN (1783-1861), the author of important inventions for facilitating the manufacture of Buckingham or French lace, was born at Duffield near Derby in 1783. During his apprenticeship to a framesmith near

Loughborough, he made an improvement in the construction of the warp-loom, so as to produce mitts of a lace-like appearance by means of it. He commenced business on his own account at Nottingham, but finding himself subjected to the intrusion of competing inventors he removed to Hathern. There he diligently prosecuted his experiments, and in 1808 constructed a machine capable of producing an exact imitation of real pillow-lace. This was by far the most expensive and complex textile apparatus till then existing; and in describing the process of his invention, Heathcoat said in 1836, "The single difficulty of getting the diagonal threads to twist in the allotted space was so great that, if now to be done, I should probably not attempt its accomplishment." Some time before perfecting his invention, which he patented in 1809, he removed to Loughborough, where he entered into partnership with Mr Lacy, a Nottingham manufacturer; but in 1816 their factory was attacked by the Luddites and the lace frames destroyed. The damages were assessed in the King's Bench at £10,000; but as Heathcoat declined to expend the money in the county of Leicester he never received any part of it. Undaunted by his loss, he began at once to construct new and greatly improved machines in an unoccupied factory at Tiverton, Devonshire, propelling them by water-power and afterwards by steam. His claim to the invention of the twisting and traversing lace machine was disputed, and a patent was taken out by a clever workman for a similar machine, which was decided at a trial in 1816 to be an infringement of Heathcoat's patent. He followed his great invention by others of much ability, as, for instance, contrivances for ornamenting net while in course of manufacture and for making ribbons and platted and twisted net upon his machines, improved yarn spinning-frames, and methods for winding raw silk from cocoons. He also patented an improved process for extracting and purifying salt. An offer of £10,000 was made to him in 1833 for the use of his processes in dressing and finishing silk nets, but he allowed the highly profitable secret to remain undivulged. In 1832 he patented a steam plough, which stood foremost in public estimation until superseded by those of Fowler and others. Heathcoat was elected member of parliament for Tiverton in 1832. Though he seldom spoke in the House he was constantly engaged on committees, where his thorough knowledge of business and sound judgment were highly valued. He retained his seat until 1859, and after two years of declining health he died in January 1861 at Bolham House, near Tiverton.

HEATING. In temperate latitudes the climate is generally such as to necessitate in dwellings, during a great portion of the year, a temperature warmer than that out of doors, and, similarly, tropical plants growing in temperate climates require artificial heat in the house in which they are preserved. Thus heating is required for health and comfort: the object of the application of science is to obtain these with the greatest degree of economy. In its aspect as to health it may be assumed that no system of heating is advisable which does not provide for a constant renewal of the air in the locality warmed. In climates such as that of the United Kingdom, the temperature of living rooms should be maintained at from 54° to 68° Fahr. in the daytime; the night temperature may be lower, but should not fall below 40°; and the humidity of the air as measured by the wet and dry bulb thermometers should show a difference of not less than 4° nor much exceeding 8° between the two thermometers, although with an ample supply of air a greater degree of dryness would probably not be found objectionable.

All heating apparatus depends upon the transference of heat from the fire to the various parts of the building which

it is intended to warm, and this transfer may be effected by radiation, by conduction, or by convection. Radiant heat is emitted and absorbed in an accelerating ratio in proportion as the difference of temperature between the radiant and the recipient increases, and, with the same difference of temperature between the recipient and the radiant, the effect of the radiant will be greater according to the increased temperature of the recipient. In other words, the ratio of the emission of heat increases with the temperature. It is thus easier to effect the warming of a given space by means of a highly-heated surface than by a surface emitting a lower temperature.

An open fire acts by radiation; it warms the air in a room by first warming the walls, floor, ceiling, and articles in the room, and these in their turn warm the air. Therefore in a room with an open fire the air of the room is, as a rule, less heated than the walls. In this case the warming of the air depends on the capacity of the surfaces to absorb or emit heat; except that the heat received by the walls may be divided into two parts, one part heating the air in contact with the wall, and the other passing through the wall to the outer surface, where it is finally dissipated and wasted. Fireplaces are sometimes constructed to assist the warming of the air of a room. For instance, in Sylvester's grate iron bars of which one end terminates under the fire are laid so as to form a projecting radiating hearth. The ventilating fireplace warms the fresh air before its admission into the room by means of gills cast on the back of the grate.

In a close stove, heated to a moderate temperature, the heat, as it passes from the fire, warms the surface of the materials which enclose and are in contact with the fire and with the heated gases. The materials next transfer the heat to the outer surface in contact with the air; and the air is warmed by the agency of this outer surface. If heated to high temperatures a stove gives out radiant heat, which passes through the air to warm the objects on which the rays impinge.

With hot-water pipes, the heat from the water heats the inner surface of the pipe, and this surface transfers its heat to the outer surface through the material of the pipes. The rate at which the heat can pass from the inner to the outer surface, and be thus utilized instead of passing away straight into the chimney, depends on the heat evolved by the fire, on the extent of surfaces exposed to the heat and their capacity to absorb and emit heat, and on the quality of the material between the inner and the outer surface as a good or bad conductor of heat. This passage of heat through a body by conduction varies directly with the quality of material, and with the difference between the temperature of the inner surface exposed to the heat and the outer surface exposed to a cooling influence, and inversely as the thickness between the surfaces. Other things being equal, copper is a better material than iron for conveying the heat from the fire to water or air; and coverings of brickwork, wood, or woollen fabrics are better adapted than iron for retaining the heat. The property which appears more than any other to make materials good non-conductors of heat is their porosity to air, and the retention of the air in their pores.

The direct warming of the air may be effected by stoves with brick or iron flues, or by hot-water or steam pipes. The sizes of the heating surfaces for this object must be proportioned to the volume of air required to be warmed for ventilation, and the degree of heat to be maintained, the thickness of the material, and its capacity for absorbing and radiating heat and for transferring heat from one surface to the other. When a large volume of air is supplied and removed for ventilation, rapidity in transferring the heat from the fuel to the air is an important consideration. Brick stoves and flues are worse conductors of heat than iron stoves or flues, but the surface of a brick stove parts with the heat which reaches it somewhat more rapidly than do the surfaces of an iron flue. The slow conducting power of the material and the greater thickness of

a brick stove prevent alternations which may take place in the fire from being felt so much as with iron stoves or flues; and therefore the brick stove warms the air more equably, without sudden variations; the air so warmed is free from objectionable elements; and where they can be conveniently applied, it is advisable to use brick stoves for warming air for ventilating purposes.

With an iron flue pipe from a stove, almost the whole heat which any fuel is capable of developing may be utilized by using a sufficiently long pipe, horizontal for the greater part of its length, to convey the products of combustion to the outer air. The heat given out by a stove pipe varies with the temperature from end to end, being of course greatest at the end next the stove, where the emission of heat is very rapid; and the amount of heat given out per square foot will vary at each point as the distance from the stove increases. The proportions also into which the heat divides itself between radiation and convection vary greatly with the temperature. Thus, with a stove pipe heated at the end nearest the stove to a dull red heat of 1230° Fahr., and of sufficient length to allow the heat to be diminished to 150° at the further end, it would be found that at the stove end of the flue pipe 92 per cent. of the total heat emitted by the pipe is given out by radiation to the walls and only 8 per cent. to the air; but at the exit end the heat is nearly equally divided, the walls receiving 55 and the air 45 per cent. Taking the whole length of such a pipe, the walls would receive 74 per cent. and the air 26 per cent. of the heat emitted. But with a flue pipe heated to lower temperatures, the air might receive half the heat or even more. When therefore the object is to heat the walls rather than the air, the temperature of the pipes should be high; and for this purpose stove pipes are more effective than hot-water or low-pressure steam pipes. At high temperatures there will be practically little difference of effect between horizontal and vertical flue pipes, because the heat given out is principally that due to radiation, which is independent of the form and position of the radiant. An adequate proportion of flue pipes to the form and size of the stove involves a large surface for the flue pipe; with a careful observance of proportion, as much as 94½ per cent. of the heat in the fuel has been utilized.

There are, however, several serious objections to iron stoves, especially for small rooms: a long flue pipe is unsightly, and on that account often inadmissible; iron stoves heat rapidly, and easily become red-hot, and the effect produced therefore is unequal. Carbonic oxide, too, has been found in air warmed by iron stoves very highly heated. It is alleged that highly-heated iron may take oxygen from the carbonic acid in the air in contact with its surface, and thus reduce the acid to carbonic oxide.

Whenever iron stoves or cookles are used for heating air, care should be taken to prevent the iron from attaining a high temperature, and with this object all iron stoves should have a lining of fire-brick, so as to prevent the fire from coming in direct contact with the iron; such an arrangement preserves greater regularity in the heating of the air. This object may be also attained by giving the stove a large surface in proportion to the fire by means of flanges or gills to carry off the heat as fast as it is generated. Iron coated with a surface of glazed enamel would enable the heat to pass rapidly from the fire to the surface, while the enamel surface would emit the heat more rapidly than the iron surface.

Hot-water pipes for warming air are free from many of the objections arising from the direct application of heat to iron, because the heat can be regulated with exactness.

A high temperature may be obtained from water without generating steam by heating it under pressure. In Perkins's high-pressure system, a continuous iron tube, about 1 inch diameter, is filled with water; about one-sixth of the length of the tube is coiled and placed in a furnace, and the remainder, forming the heating surface, is heated by the circulation of the water. At the highest level to which the tube is carried it is enlarged so as to allow of a space for expansion of the heated water equal to 5 per cent. of the contents of the small tube.

Pipes may be heated by either hot water or by steam. The higher the temperature, the greater is the comparative effect in warming air; therefore, with a small heating surface, steam pipes are more efficient than hot-water pipes, and steam at a high pressure more efficient than low-pressure steam. The efficient action of hot-water pipes depends upon the upward flow of the heated and expanded water as it passes from the boiler, the passage being made as direct as possible, and so protected as to lose little heat between the boiler and the place where the heat is to be utilized. The return pipe, which brings back the water after it has been cooled down by the abstraction of heat in warming the air, should be passed into the bottom of the boiler as directly and in as uniform a line from the place where the heat has been used as possible. The velocity of flow in the pipes will depend upon the temperature at which the water leaves the boiler, the height to which the heated water has to rise, and the temperature at which it passes down the return pipe back into the boiler. The efficiency of a hot-water apparatus will be regulated by these conditions, by the size of the pipe, and by such other conditions as affect the flow

of water in pipes. When the boiler or source of heat is very near the level of the pipes for heating the air, the average temperature which can be obtained in the pipes will be lower than when the vertical column is long. The heating surface must be regulated with reference to this difference of level. It may further be assumed that with small pipes, the temperature being constant, the velocity of flow in the pipe necessary to furnish a given amount of heat will vary in the ratio of the length of the pipe. When the water circulates through the pipes by virtue of the difference of temperature of the flow and return currents only, it is impossible to count upon a greater mean temperature of the pipes than from 160° to 180°, because above that temperature the water in the boiler begins to boil. To obtain a sufficient velocity of circulation for long distances, or with small differences of level, a forced circulation may be resorted to. This has been done by Messrs Easton and Anderson at the county lunatic asylum at Banstead, in the following manner. The whole hot-water service is supplied from boilers placed at one end of the asylum buildings, which extend to a distance of several hundred yards. There are two pipes; one of them, which may be called the flow pipe, is connected directly with the boiler, terminating at the point furthest from the boiler in a dead end; the other, which may be termed the return pipe, is parallel to the first, and terminates at one end in a cistern which is placed about 6 feet above, and supplies the boiler. At the other end furthest from the cistern the second pipe also terminates in a dead end. At each pavilion or place to which hot water is required to be conveyed, there is a connexion between the two pipes, which can be closed or opened at will; when it is opened, the water can pass from the flow to the return pipe. In the second, or return pipe, near the point where it ascends to the cistern, is placed a rotary pump, or fan wheel, which is always kept revolving. When the openings are all closed between the two pipes, this pump or fan simply slips through the water; but as soon as the return pipe obtains a supply of water from any of the openings between it and the flow pipe, a circulation is established.

The following diagram, resulting from Mr Anderson's experiments, published in the *Journal of the Institution of Civil Engineers* for 1877, shows the total units of heat given out by cast-iron and wrought-iron pipes per square foot of surface per hour for various differences of temperature applicable either to hot-water or steam pipes. Suppose, for example, it is required to know how much heat will be given out by 4-inch cast-iron, or 2-inch wrought-iron pipes at 190° in a room, the temperature of which is 60°; the difference of temperature is 130°, and corresponding to this will be found 232.7 units for 4-inch pipes and 356 units for 2-inch wrought-iron pipes per square foot per hour.

Diagram for ascertaining the heat given out by 4-inch cast-iron and 2-inch wrought-iron pipes at various differences of temperature. The dotted line shows the 4-inch, and the solid line the 2-inch pipes.

The amount of heating surface to be afforded with hot-water pipes depends mainly upon the volume of air to be admitted and removed, and the temperature desired to be maintained, but in any given building there are other circumstances to be taken into account, viz., the position, aspect, subsoil, temperature of locality, thickness of walls, size and form of windows, and other influences affecting the temperature of the incoming air, or causing loss of heat. An empirical rule has been laid down that in a dwelling-house 1 square foot of heating surface is required for every 65 cubic feet of space to be warmed, and in a greenhouse 1 square foot to every 24 cubic feet. This empirical rule does not take into account the sanitary considerations as to the renewal of air.

Steam-heated pipes present important advantages in some cases over hot-water pipes for heating purposes, because of the higher temperature to which the pipes can be raised, their consequent smaller size, and the facility of conveying the heat to a distance. Steam heating may be applied directly; and the waste steam from an engine is also applicable for heating.

The direct application of steam heating on a large scale has been made at Lockport, New York. About 200 houses in the city are heated from a central supply through about 3 miles of piping, radiating from a boiler-house, which contains two boilers 16 feet by 5 feet, and one boiler 8 feet by 8 feet. These boilers are fired during the winter to a pressure of 35 lb to the inch, with a consumption of 4 tons of anthracite coal in twenty-four hours. The boiler pressure of 35 lb in winter and 25 lb in summer is maintained through a total length of 3 miles of piping up to the several points of consumption, where there is a cut-off under the control of the consumers. The first 600 feet of mains from the boilers are 4 inches in diameter. There are 1400 feet of 3-inch pipes, 1500 feet of 2½-inch pipes, and 2000 feet of 2-inch pipes. The supply pipes from these mains to the houses are 1½ inches in diameter, and within each house ¾-inch pipes are used. In addition to the cut-off tap from the main under the control of the consumer, there is a pressure valve regulated to a 5-lb pressure under the control of the company; and beyond this is an ingeniously constructed meter, which indicates, not only the total consumption in cubic feet of steam, but also the quantity of steam in each apartment. At each 100 feet of main an expansion valve, like an ordinary piston and socket, is inserted, allowing an expansion in each section of 100 feet of 1½ inches for the heat at 35-lb pressure. No condensation occurs in the mains. They are covered with a thin layer of asbestos paper next the iron, then a wrapping of Russian felt, and finally manilla paper, and the whole is encased in timber bored out three-quarters of an inch larger than the felt-covered pipes, and laid along the street like gas-pipes. The distribution of heat in the apartments is by means of radiators consisting of inch pipes, 30 inches long, placed vertically either in a circle or as a double row, and connected together at top and bottom, with an outlet pipe for the condensed water, which escapes at a temperature a little below boiling, and is sufficient for all the domestic purposes of the house, or it may be used as accessory heating power for horticultural and other purposes. The steam has also been applied at a distance of over half a mile from the boilers for motive power, and two steam engines of 10-horse and 14-horse power are worked from the boilers at a distance of half a mile with but a slightly increased consumption of fuel. The laid-on steam is also used for cooking purposes, for boiling, and even for baking. As in the case of gas supply, the steam supply company lay their pipes up to the houses, the consumer paying for all internal pipes, fittings, and radiators. In a moderately-sized eight-roomed house the expense of these amounted to \$150, and in larger houses with costlier fittings to \$500.

Boulton's system of heating with exhaust or waste steam is devised to cause the steam from a steam engine to travel long distances without any back pressure on the engine. It is especially applicable to drying rooms in which 150° Fahr. has been obtained by a large heating surface; for a lower temperature less heating surface is required. The capacity of heating by exhaust steam is nearly in a ratio with the fuel expended in the boiler. There is some cooling in passing through the engine, and in the conveyance along the pipes to the rooms to be heated, but this loss is comparatively small if the pipes and the cylinder are covered with a good non-conductor, and the condensed water is taken back hot into the boiler. Thus, if the steam be taken from the boiler direct to the pipes at five atmospheres, the temperature would be 307°, and if a comparative capacity of steam were allowed to pass through the engine to create power, and discharged into the pipes at one atmosphere, it would decrease in temperature to 213°; but it would increase in bulk according to the expansion; and thus to obtain nearly the same temperature in the room the heating surface should be increased.

With an engine of 17-inch cylinder and 25-horse power nominal, the exhaust steam has been made to travel 200 yards in a direct line, as well as to pass into various branches, amounting in the aggregate to about 2386 yards (or 1½ miles) of 1½-inch pipes. After this it warms the water for the boiler, and the steam is not all used up. The whole efficiency of the system depends upon so arranging the pipes as to prevent back pressure. Mr Boulton assumed that one-horse power if properly applied should warm about 30,000 cubic feet of space, subject to reductions for window space, wall space, the number of cubic feet of air allowed to escape for ventilation, and other considerations, and lays down the following empirical rule, viz.:—1 square foot of steam pipe is allowed for each 6 square feet of glass in the window, 1 for every 6 cubic feet of air escaping for ventilation per minute, and 1 for every 120 feet of wall, roof, or ceiling, adding about 15 per cent. for contingencies.

Wrought-iron pipes 1½-inch bore are the most economical for steam, as they afford a large heating surface with small area. In heating living rooms by steam, the high temperature of the pipes affords one of the advantages of an open fire, viz., warmth by radiation, and combines with this the advantage which hot-water pipes possess of directly warming the air. (D.G.)

HEBBEL, FRIEDRICH (1813-1863), a German poet and dramatist, was born of peasant parents at Wesselburen, in Schleswig-Holstein, 18th March 1813. In his fourteenth year he obtained a humble clerkship in his native parish, but already his ambition was soaring towards higher things. At an early period he began to practise poetical composition, and several of his poems published in the *Modezeitung* at Hamburg awakened such interest that several gentlemen procured him in his twenty-second year the means of preparing himself in Hamburg for the university. He afterwards studied philosophy and history at Heidelberg and Munich. In 1841 he returned to Hamburg, where he published his first tragedy, *Judith*. In a journey which he made to Copenhagen in 1842 he formed the acquaintance of Thorwaldsen and Oehlenschläger, and acquired the more substantial advantage of a travelling annuity from the king of Denmark. He accordingly visited Paris, after which he went to Italy, where he remained several years, staying principally at Rome, Pisa, and Palermo. Having in the spring of 1846 stopped at Vienna on his way home to Germany, he made the acquaintance of the actress Christine Engehaus, whom he married in May of the same year. His marriage led him to take up his permanent residence in Vienna, and probably deepened his interest in dramatic composition, which from that time chiefly occupied his attention. He died in 1863. His principal dramas are *Genoveva*, 1843; *Maria Magdalena*, 1844; *Julia*, 1851; *Agnes Bernauer*, 1855; and *Die Nibelungen*, 1862. They exhibit considerable skill in the portraiture of character, great glow of passion, and a true feeling for dramatic situations, but their poetic effect is marred by frequent extravagances which border on the grotesque, and by the introduction of incidents the unpleasant character of which is not sufficiently relieved. In many of his smaller poems his undoubted poetic gifts found a truer and more artistic utterance.

His collected works appeared at Hamburg in 12 vols. (1865-68). His biography by Emil Kuh was published at Vienna in 1877.

HEBE, in Greek mythology, is a personification of the blooming freshness and youth of nature. Originally she appears almost identical with the pure Greek Aphrodite (as distinguished from the Oriental goddess). Hebe is the daughter of Zeus and Hera, as Aphrodite of Zeus and Dione; but Dione and Hera are only two names for the same goddess. Like Aphrodite, Hebe is called the most beautiful of the gods (Pind., *N.*, 10, 17). In Sicyon and Phlius Hebe is called Dia, a regular epithet of Aphrodite. In Phlius, where Hebe was worshipped on the citadel in a temple where no image of her was allowed and to which right of asylum was attached, a festival called *κισσοτόμοι* was celebrated to her every year; and ivy was sacred also to Aphrodite. It is in accordance with the close resemblance between Aphrodite and Core that Hebe also has many points of analogy with the latter, to whom she is compared by Gerhard and Welcker (*Gr. Gött.*, I. 369). According to the custom for the unmarried daughters of a family, Hebe acts in the Homeric poems as a sort of attendant to the gods and especially to her own mother Hera. She offers the cup to the gods, just as on earth the women, and especially the youngest daughter, did to guests and to warriors departing or returning. She bathes Ares (*Il.*, v. 905), as Polycaste does Telemachus. She harnesses the horses for Hera (*Il.*, v. 722). She appears very often in connexion with the worship of Hera. A statue of her by Naucydes stood beside the Hera of Polyclitus in the Heræum at Argos. Praxiteles placed statues of her and Athene beside that of Hera in the temple at Mantinea, and Kekulé (*Ihebe*) maintains that the artistic conception of Hebe which prevailed in the finest period of Greek art

was a slight modification of that of Hera, and he believes that a bust, now in private possession, is the single remaining example of its kind. Welcker's opinion that the so-called Farnese Flora is really a Hebe has not been generally accepted. In later art she is often represented, like Ganymedes, caressing the eagle; and it is possible that the epithet Ganymeda, by which she was called in Phlius, is not really ancient, but arises from the supposed analogy of her office with that of Ganymedes. The meaning of the word Hebe tended to transform the goddess into a mere personification of the eternal youth that belongs to the gods, and this conception is frequently met with. Then she becomes identical with the Roman Juventas, who is simply an abstraction of an attribute of Jupiter Juventus, the god of increase and blessing and youth. By a most transparent allegory it was said that Juventas and Terminus alone of all the gods refused to give way when the temple of Jupiter Capitolinus was being built. Perhaps the most interesting point about Hebe is her connexion with Heracles. When he was received among the gods and reconciled to Hera, Hebe was given him in marriage. This legend appears only in a doubtful line of Homer (*Od.*, xi. 603); but Hesiod (*Th.*, 950) and Pindar (*N.*, 10, 17) also know it. They were worshipped together in the Cynosarges at Athens, and represented side by side on the Amyclæan throne. The apotheosis of Heracles and his marriage with Hebe became a favourite subject with poets and painters. Many instances occur on vases, though several of those enumerated by Kekulé are otherwise explained by other writers on art.

HEBER, REGINALD (1783-1826), a distinguished prelate and hymn-writer, was born at Malpas in Cheshire in 1783. He early showed remarkable promise, and was entered in November 1800 at Brasenose College, Oxford, where he proved a distinguished student, carrying off prizes for a Latin poem entitled *Carmen Seculare*, an English poem on *Palestine*, and a prose essay on *The Sense of Honour*. In November 1804 he was elected a fellow of All Souls College; and, after finishing his distinguished university career, he made a long tour on the Continent. He was admitted to holy orders in 1807, and was then presented to the family living of Hodnet in Shropshire. In 1809 Heber married Amelia, daughter of Dr Shipley, dean of St Asaph. He was appointed Bampton lecturer for 1815, prebendary of St Asaph in 1817, preacher at Lincoln's Inn in 1822, and bishop of Calcutta in January 1823. Before sailing for India he received the degree of D.D. from the university of Oxford. In India Bishop Heber laboured indefatigably, not only for the good of his own diocese, but for the spread of Christianity throughout the East. Animated by apostolic zeal, he undertook numerous tours in India, consecrating churches, founding schools, and discharging other Christian duties. Such devotion to his work in a trying climate told severely on his health. At Trichinopoly he was seized with an apoplectic fit when in his bath, and expired on 3d April 1826.

Heber was a man of profound learning, refined literary taste, and great practical energy. His Christian character manifested all the beauty and simplicity of the days of the early church. As a poet he has attained a high place. His *Palestine* is generally considered the best prize poem ever written at Oxford. Heber's fame rests mainly on his hymns, which, as literary compositions, rank among the best in the English language. These beginning as follows may be instanced:—"Lord of mercy and of might"; "Brightest and best of the sons of the morning"; "By cool Siloam's shady rill"; "Lo, He comes in clouds descending"; "The Lord of might from Sinai's brow"; "Jesus Christ is risen to-day"; "Holy, holy, holy, Lord God Almighty"; "From Greenland's icy mountains"

"Thou art gone to the grave! but we will not deplore thee." Heber's hymns and other poems are distinguished by finish of style, pathos, and soaring aspiration; but they lack originality, and are rather rhetorical than poetical in the strict sense.

Heber was a voluminous author, as may be seen from the following works:—*Palestine; a Poem, to which is added the Passage of the Red Sea*, 1809; *Europe: Lines on the Present War*, 1809; *The Personality and Office of the Christian Comforter asserted and explained*, being the Bampton Lectures for 1815; *The Whole Works of Bishop Jeremy Taylor, with a Life of the Author, and a Critical Examination of his Writings*, 1822; *Hymns written and adapted for the Weekly Church Service of the Year, principally by Bishop Heber*, 1827; *A Journey through India*, 1828; *Sermons preached in England, and Sermons preached in India*, 1829; *Parish Sermons*, 1837.

For further information about Heber see his *Life*, by his widow, 1830, which also contains a number of Heber's miscellaneous writings; *The Last Days of Bishop Heber*, by Thomas Robinson, A.M., archdeacon of Madras, 1830; and *Memorials of a Quiet Life*, by Augustus J. C. Hare, 1874.

HEBERDEN, WILLIAM (1710–1801), a practical physician of some celebrity, was born in London in the year 1710. In the end of 1724 he was sent to St John's College, Cambridge, where he obtained a fellowship about 1730, became master of arts in 1732, and took his degree in physic in 1739. He remained at Cambridge about ten years longer as a practitioner of physic, and gave an annual course of lectures on materia medica. In 1746 he became a fellow of the Royal College of Physicians in London; and two years afterwards he left Cambridge to establish himself in London, where he was elected a fellow of the Royal Society in 1769, and was employed in a very extensive medical practice for more than thirty years. Latterly he passed his summers at a house which he had taken at Windsor, but he continued his practice during the winter for some years longer. In 1778 he was made an honorary member of the Royal Society of Medicine at Paris. He died 17th May 1801.

Heberden's first publication seems to have been a short essay on the incongruous composition of the mithridate and theriac, entitled *Antitheriaca* (1745). He also wrote several papers for the Royal Society, which were published in its *Transactions*; and he was one of the principal contributors to the first three volumes of the *Medical Transactions*, published, in a great measure at his suggestion, by the College of Physicians. He is, however, best known by his *Commentaries on the History and Cure of Diseases*, the result of careful notes made in his pocket-book at the bedside of his patients. In accordance with his directions the work was published posthumously in 1802; prefixed to it is a short notice of his life.

HÉBERT, JACQUES RENÉ (1755–1794), a French revolutionist, surnamed from the newspaper he edited "Le Père Duchesne," was born of obscure parents at Alençon in 1755. He came at an early age to Paris, where he lost more than one situation through malversation, and was in abject poverty when the occurrence of the French Revolution opened up to him a career in which he obtained considerable temporary success and permanent notoriety. Having shown great readiness and proficiency in a style of writing and of oratory which appealed to the worst feelings of the revolutionary mob, he soon acquired great influence in the clubs, and was chosen to oppose the constitutional paper *Le Père Duchesne* by editing a revolutionary paper of the same name. The scurrilous and extravagant language of the new print exactly coincided with the sentiments of the class to whom it was addressed, and it contributed not a little to several of the worst and most violent manifestations of the revolutionary spirit. It had a very beneficial influence on the fortunes of its editor, who after the 10th August 1792 was one of the chief members of the revolutionary commune, and on the 2d September was appointed substitute to the *procureur syndic*. On the 24th May 1793 an order was sent out for his arrest by the more moderate party of the commune on the ground that he was plotting their assassination, but on account of a formidable outbreak of the mob he was set at liberty,

and when he appeared again at the commune he was presented with a civic crown. Having been appointed a member of the commission to examine Marie Antoinette, he with unsurpassed moral baseness foully accused her of a crime too scandalous to be mentioned. Along with several of his colleagues he invented the worship of the goddess "Reason," and subsequently he organized a party of ultra-revolutionists known as the Hébertists or *enragés*. The faction were, however, arrested by the committee of public safety, and on the 24th March 1794 were led forth to execution. Hébert behaved with great cowardice at his trial, and died amid the jeers and insults of the mob over whose passions he had at one time exercised such sway and to whom he owed his promotion to power.

He was the author of *Vitres cassées par le véritable Père Duchesne*, 1791; *Vie privée de l'abbé Maury*, 1790; *Petit carême de l'abbé Maury*, 1791; *Nouvelle lanterne magique*, 1792.

HEBREW LANGUAGE AND LITERATURE. The name *Hebrew* (Latin, *Hebræus*; Greek, Ἑβραῖος) is a transcription of 'ēbráyā, the Aramaic equivalent of the original Old Testament word עִבְרִי, 'ibrī, pl. 'ibrīm, which is the proper Gentile name of the people who also bore the collective name of Israel or Children of Israel (B'né Israel). The name of Israel with its sacred associations in the patriarchal history is that by which the Old Testament writers prefer to designate their nation; and this circumstance, combined with the fact that the Sacred Text frequently employs the term Hebrews where foreigners are introduced as speaking or spoken to (e.g., Exod. ii. 6; 1 Sam. iv. 6, 9; Gen. xl. 15; Ex. iii. 18), has led to the conjecture that the name of Hebrews (men from the other side, scil. of the Euphrates) was originally given to the descendants of Abraham by their Canaanite neighbours, and continued to be the usual designation of the Israelites among foreigners, just as the Magyars are known to other Europeans as Hungarians (foreigners), as we call the High-Dutch Germans (warriors), or as the Greeks gave the name of Phœnicians to the people that called themselves Canaanites.¹ A closer view of the case does not confirm this conjecture. The name of Israel is often found in the Old Testament in the mouth of foreigners, and the whole *usus loquendi* is explained by the observation that the Gentile noun corresponding to the collective "Israel" is regularly "Hebrew" and not "Israelite," the latter word being rare and apparently of late formation.² Nor has the word Hebrew been hitherto found in the early monuments of other Eastern nations; for the identification proposed by Chabas which finds the Hebrews in the hieroglyphic Apurū is more than doubtful.³ On the other hand the name of Israel appears on the stone of Mesha king of Moab, and perhaps has been deciphered on Assyrian monuments.⁴

The form 'ibrī is, in the language of Semitic grammarians, a relative noun, presupposing the word 'Eber as the name of the tribe, place, or common ancestor, from whom the Hebrews are designated. Accordingly we find Eber as a nation side by side with Assyria in the obscure poetical passage Num. xxiv. 24, and Eber as ancestor of the Hebrews in the genealogical lists of Gen. x., xi. Here we must apparently distinguish two records.⁵ According to

¹ See especially Gesenius, *Geschichte der Hebräischen Sprache und Schrift*, pp. 9 seq.; most recently Kautzsch in Riehm's *Handwörterbuch*.

² In 2 Sam. xvii. 25 Israelite must be corrected to Ishmaelite, as in the parallel passage 1 Chron. ii. 17.

³ Chabas, *Mélanges Égyptologiques*, i. 42; Ebers, *Ägypten und die Bücher Moses*, i. 316; Brugsch-Bey, *Geschichte Ägyptens*, 582 (Eng. trans., ii. 128–9); Birch, *Ägypt.*, p. 128.

⁴ Schrader, *Keilschriften und Geschichtsforschung* (Giesesen, 1878), pp. 359, 536, gives the latest arguments for this now undisputed reading.

⁵ See De Goeije in the *Theol. Tijdschrift*, 1870, p. 443; and Wellhausen in *Jahrb. f. D. Theol.*, 1876, p. 395.

Gen. xi. (and Gen. x. 24) Eber is the great-grandson of Shem through Arphaxad, and ancestor of Terah through Peleg, Reu, Serug, and Nahor. These are not to be taken as the names of individual men. Several of them are designations of places or districts near the upper waters of the Euphrates and Tigris, and among other circumstances the place at the head of the series assigned to the district of Arrapachitis (Arphaxad), through which a migration from Ararat to the lands occupied by the Semites in historical times would first pass, suggests the probability that the genealogy is not even meant to exhibit a table of ethnological affinities, but rather presents a geographical sketch of the early movements of the Hebrews, who are personified under the name of Eber. If this is so we can hardly venture to assert (with some scholars) that the author of the list (the Levitical Elohists) extended the name of Hebrews to all descendants of Terah.¹ The case is different with another and apparently older record of which a fragment seems to be preserved in Gen. x. 21, 25-30. Here there is no intermediate link between Shem and Eber. Sons of Shem and sons of Eber appear to be coextensive ideas, and to the latter are reckoned not only the descendants of Peleg (Aramæans, Israelites, Ishmaelito Arabs, &c.), but the South Arabian tribes of Joktan. We possess no information which casts light on this wide conception of the sons of Eber, and in the ordinary language of the Old Testament Hebrew and Israelite are strictly synonymous.

Compare, however, the interesting conjectures of Sprenger, *Atte Geographic Arabiens* (Bern, 1875), p. 294, who identifies Peleg with Falag in Central Arabia, and finds in the record a witness to the truth of the view that Arabia is the original centre of the Semitic dispersion, a view which is shared by other scholars, as Hitzig (*Geschichte Israels*, pp. 26, 39), and Schrader (*Z. D. M. G.*, 1873, pp. 397-424). In this connexion it is perhaps worth while to note the Arabic Gentile name 'Obri, belonging to 'Obra, a minor division of the Joktanic tribe of the Azd (*Lubb-il-lubbâ*, ed. Veth, p. 175).

When it is recognized that Eber in Genesis is not an actual personage but an ethnological or geographical abstraction, we are thrown back on etymological conjecture as to the origin of the name of Hebrews. 'Eber means the further bank of a river, from a root meaning *to cross*. Hence in Gen. xiv. 13 the Septuagint renders Abram the Hebrew by ὁ περάτης, "the crosser."² Grammatically more accurate, while resting on the same etymology, is the rendering of Aquila, ὁ περάτης, "the man from the other side" of the Euphrates, which is the explanation of Jewish tradition (*Brâshit Rabba*, and Rashi) and still generally adopted. It is, however, far from satisfactory, and almost of necessity depends on the theory that the name was fixed upon the Hebrew immigrants by the earlier inhabitants of Canaan.³ A modified form of the etymology takes 'eber in the Arabic sense of a river bank, and makes the Hebrews "dwellers in a land of rivers" (Steiner in the *Bibel-Lex.*, ii. 613). This goes well with Peleg (watercourse), as in Arabia we have the district Falag, so named because it is furrowed by waters (Sprenger, *Geog. Arab.*, p. 234).⁴

The name "Hebrew Language."—By the Hebrew language we understand the ancient tongue of the Hebrews in Canaan—the language in which the Old Testament is composed, with the exception of the Aramaic passages (Jer. x. 11; Ezra iv. 8-vi. 18; vii. 12-26; Dan. ii. 4-vii. 28). But

we do not find that this language was called Hebrew by those who spoke it. It is the *lip*, i.e., speech of Canaan, Isa. xix. 18, or, as spoken in Southern Palestine, יהודית Jewish (2 Kings xviii. 26; Neh. xiii. 24). The later Jews call it the *holy tongue* in contrast to the *profane* Aramaic dialect (commonly though improperly enough called Syro-Chaldaic) which long before the time of Christ had superseded the old language as the vernacular of the Jews. This change had already taken place at the time when the expression "in Hebrew" (ἐβραϊστὶ) first occurs (Prologue to Sirach); and both in the Apocrypha and in the New Testament the ambiguous term, naming the language after those who used it, often denotes the contemporary vernacular, not the obsolete idiom of the Old Testament. But the other sense was admissible (e.g., Rev. ix. 11, and so frequently in Josephus), and naturally became the prevalent one among Christian writers who had little occasion to speak of anything but the Old Testament Hebrew.⁵ In modern usage it is incorrect to call the Jewish Aramaic Hebrew; though uneducated Jews apply the name even to the corrupt German and Spanish jargons which they are accustomed to write and print in Hebrew characters.

Character and Philological Relations of Hebrew.—Hebrew is a language of the group which since Eichhorn has generally been known as Semitic, and of which Arabic and Ethiopic (Southern Semitic), the various dialects of Aramaic, and the language of the Assyrian and Babylonian cuneiform inscriptions are the other chief representatives. From its geographical position as the language of Palestine between the Aramæans of the north and the Arabs of the south, Hebrew has been called Middle Semitic. Or Aramaic Assyrian and Hebrew may be grouped together as Northern Semitic in contrast to Arabic and Ethiopic. The affinities of the Semitic languages are so close that they may fairly be compared with a sub-group of the Indo-Germanic family—for example, with the Teutonic languages. The fundamental unity of the Semitic vocabulary is easily observed from the absence of compounds (except in proper names) and from the fact that almost all words are derived from their roots in definite patterns (*measures*) as regular as those of grammatical inflexion. The roots regularly consist of three consonants (seldom four or five), the accompanying vowels having no radical value, but shifting according to grammatical rules to express various embodiments of the root idea. The triliteral roots are substantially common to the whole Semitic group, subject to certain consonantal permutations, of which the most important are strikingly analogous to those laid down by Grimm for the Teutonic languages.

There are four sounds in Arabic unknown to Hebrew and Aramaic, and for which the former regularly has a sibilant, the latter a lingual—in one case a deep guttural. This guttural (V), and the palatal letters which in the following table are represented by *d, s, t, z*, are peculiar Semitic sounds.

Arabic.	Hebrew.	Aramaic.
th ث	sh שׁ	ת ת
dh ذ	z ז	ד ד
z ظ	s ס	ס ס
d ض	s ס	צ [also s]

On the last equation see Lagarde, *Semitica*, i. 22; Noldeke in *Z. D. M. G.*, xxxii. 405; and on the permutation of consonants in general, Merx, *Gram. Syr.*, § 24; Stade in *Morgenl. Forschungen* (1875), p. 179 seq. Whether the Arabic or Aramaic forms are the older is disputed. No one maintains that the Hebrew forms are original.

⁵ The term "Hebrew language" seems to have originated with the Greeks or Hellenists. Philo, however, calls the language of the Old Testament Chaldee (*De Vita Mosi*, ii. 5, 6; cf. Jerome on Dan. i.). On the use of the expression "Hebrew language" in the Talmud; see Berliner, *Beiträge zur heb. Gr.* (Berlin, 1879), p. 6.

¹ The Terahites, according to other testimonies, are Aramæans (Gen. xxii. 20 seq.; Deut. xxvi. 5), but our Elohists, who can hardly have written before the captivity, makes Aram a separate offshoot of Shem, having nothing to do with Eber (Gen. x. 22, 23).

² Compare Jerome, *Quæst. Hebr.* on the passage, and Theodoret, *Qu. LXI.* in Gen.

³ Compare Ewald, *Gesch. Israels* (3d ed.), i. 407 seq. (Eng. trans., I. 284), where also other etymologies are noticed.

⁴ Complete ignorance of Hebrew made it possible for early Christian writers to derive the name of the Hebrews from Abraham. See Bochart's *Phaleg*, lib. ii., cap. 14. Other guesses will be found in the *Onomastica*.

Derivation from the roots and inflexion proceed partly by the reduplication of root letters and the addition of certain preformatives and afformatives (more rarely by the insertion of formative consonants in the body of the root), partly by modifications of the vowels with which the radicals are pronounced. Almost every root expresses in its origin something that can be grasped by the senses, and the mechanism by which words are formed from the root is adapted to present sensible notions in a variety of *nuances* and in all possible embodiments and connexions, so that there are regular forms to express in a single word the intensity, the repetition, the production of the root idea—the place, the instrument, the time of its occurrence, and so forth. Thus the expression of intellectual ideas is necessarily metaphorical, almost every word being capable of a material sense or at least conveying the distinct suggestion of some sensible notion. For example, the names of passions depict their physiological expression; “to confer honour” means also “to make heavy,” and so on. The same concrete character, the same inadequacy to convey purely abstract thoughts without a substratum appealing to the senses, appears in the grammatical structure of the Semitic tongues,—for example, in the absence of the neuter gender, in the extreme paucity of particles, in the scanty provision for the subordination of propositions, which deprives the Semitic style of all involved periods and reduces it to a succession of short sentences linked by the simple copula *and*. The fundamental element of these languages is the noun, and in the fundamental type of sentence the predicate is a noun set down without any copula and therefore without distinction of past, present, or future time. The finite verb is developed from nominal forms (participial or infinitive), and is equally without distinction of time. Instead of tenses we find two forms, the perfect and the imperfect, which are used according as the speaker contemplates the verbal action as a thing complete or as conditional, imperfect, or in process. It lies in the nature of this distinction that the imperfect alone has moods. In their later stages the languages seek to supply the lack of tenses by circumlocutions with a substantive verb and participles. Other notable features common to the Semitic tongues are the use of appended suffixes to denote the possessive pronouns with a substantive, or the accusative of a personal pronoun with a verb, and the expression of the genitive relation by what is called construction or annexation, the governing noun being placed immediately before the genitive, and if possible slightly shortened in pronunciation so that the two words may run together as one idea. A characteristic of the later stages of the languages is the resolution of this relation into a prepositional clause.

These and other peculiarities are sufficient to establish the original unity of the group, and entitle us to postulate an original language from which all the Semitic dialects have sprung. Of the relation of this language to other linguistic stems, especially to the Indo-Germanic on the east and the North-African languages on the west, we cannot yet speak with certainty; but it appears that the present system of triliteral roots has grown out of an earlier biliteral system which, so far as it can be reconstructed, must form the basis of scientific inquiry into the ultimate affinities of the Semitic group.¹

Before the rise of comparative philology it was a familiar opinion that Hebrew is the original speech of mankind. Taken from the Jews, and as already expressed in the Palestinian Targum on Gen. xi. 1, this opinion drew its

main support from etymologies and other data in the earlier chapters of Genesis, which, however, were as plausibly turned by Syriac writers in favour of their own tongue.² Till quite recently many excellent scholars (including Ewald) have claimed for Hebrew the greatest relative antiquity among Semitic tongues. But though Hebrew has by far the oldest literature, this does not prove that its structure comes nearest to the original Semitic language. And it is now generally recognized that in grammatical structure the Arabic, shut up within its native deserts till the epoch of Islam, preserved much more of the original Semitic forms than either Hebrew or Aramaic. In its richer vocalization, in the possession of distinct case-endings, in the use for feminine nouns of the affirmative *t*, which in the northern dialect has passed through *h* (originally audible as in Egyptian Arabic) into a mere vowel, in the more extensive range of passive and modal forms, and in other refinements of inflexion, Arabic represents no later development, but the original wealth and primitive subtlety of Semitic speech, as appears not only from fragmentary survivals in the other dialects but from an examination of the process of decay which has brought the spoken Arabic of the present day into a grammatical condition closely parallel to the Old Testament Hebrew. But while Arabic is in many respects the elder brother, it is not the parent of Hebrew or Aramaic. Each member of the group had an independent development from a stage prior to any existing language, though it would seem that Hebrew did not branch off from Aramaic so soon as from Arabic, while in its later stages it came under direct Aramaic influence.

Among the points in which Hebrew differs both from Arabic and Aramaic may be mentioned the consonantal relations already spoken of, the system of tone long vowels, the use of Waw consecutive, the η of the causative and reflexive stems and of the article, and the compensation for omitting the reduplication of gutturals and *r* by lengthening a preceding vowel.³ Again, Hebrew agrees with Arabic against Aramaic in possessing a prefixed article, in the use of the Nifal (Arab. VII.), and in other minor points. But in more notable features Hebrew and Aramaic agree against Arabic, as in the absence of broken plurals, the place of the accent, the aspiration of certain letters whenever they are preceded by a vowel sound, and the substitution of *y* for *w* as the first radical of roots. To give further details would carry us too far into comparative grammar. Speaking generally, it may be said that Hebrew is less copious in vocabulary than Arabic (in which tongue, however, the abundance of synonyms is largely due to an artificial combination of several dialects), and less rich in subtle distinctions of grammatical form and refinements of syntax. On the other hand, Hebrew is much superior to Aramaic in flexibility of structure, in fulness of vowels, and in all the qualities which adapt a language for poetical expression.

Geographical Sphere and History of Hebrew as a Spoken Language.—The Hebrew spoken by the Israelites in Canaan was separated only by very minor differences (like those of our provincial dialects) from the speech of neighbouring tribes. We know this for the Moabite language from the stone of Mesha; and the indications furnished by proper names, as well as the acknowledged affinity of Israel with these tribes, make the same thing probable for Ammon and Edom. More remarkable is the fact that the Phœnicians and Canaanites, with whom the Israelites acknowledged no brotherhood, spoke a language which, at

² Theodoret (*Quæst. in Gen.*), xi., Barhebræus, and others cited by Assemani. *Bib. Or.*, iii. 314. The same opinion appears among the Babylonian Jews (Rab in *Synh.*, 38b). Conversely, Jacob of Sarug concedes the priority of Hebrew (see *Z. D. M. G.*, xxv., p. 520). The Arabs, whose language is in many points older than either, yield priority to Hebrew (Abulfeda, *H. A.*, p. 18), or to Syriac (Tabari, i., 220; Abu 'Isa in Abulfeda, p. 148), the language of the race to which they owed their first knowledge of letters.

³ The verbal prefixes *ha*, *hith*, appear in Palestinian Aramaic, and the Aramaic dialects also exhibit some cases of a lengthened vowel before *r* (Nöldeke, *Mand. Gram.*, p. 17). On the other hand, the transcription of the LXX. shows that Hebrew once could double *r*.

¹ Renan, *Histoire des Langues Sémitiques*, sketches the history of research in this direction. Noteworthy are the remarks of Lagarde, *Symmetica*, p. 121. On survivals from the biliteral stage, see Nöldeke, *Mandäische Gram.*, p. 96.

least as written, differs but little from Biblical Hebrew. This observation has been used in support of the very old idea that the Hebrews originally spoke Aramaic, and changed their language in Canaan. But an exacter study of the Phœnician inscriptions shows differences from Hebrew which suffice to constitute a distinct dialect, and combine with other indications to favour the view that the descendants of Abraham brought their Hebrew idiom with them from Haran. And in this connexion it is important to observe that the old Assyrian, which preceded Aramaic in regions with which the book of Genesis connects the origins of Abraham, is in many respects closely akin to Hebrew.¹ As the origin of Hebrew is lost in the obscurity that hangs over the early movements of the Semitic tribes, so we know very little of the changes which the language underwent in Canaan. The existence of local differences of speech is proved by Judges xii. 6; but the attempt to make out in the Old Testament records a northern and a Judæan dialect, or even besides these a third dialect for the Simeonites of the extreme south,² has led to no certain results. In general it may be said that the Biblical text supplies inadequate data for studying the history of the language. Semitic writing, especially a purely consonantal text such as the Old Testament originally was, gives an imperfect picture of the very grammatical and phonetic details most likely to vary dialectically or in course of time. The later punctuation (including the notation of vowels), and even many things in the present consonantal text, represent the formal pronunciation of the Synagogue as it took shape after Hebrew became a dead language—for even the Septuagint has often a more primitive pronunciation of proper names. This modern system being applied to all parts of the Old Testament alike, many archaisms were obliterated or disguised, and the earlier and later writings present in the received text a grammatical uniformity which is certainly not original. It is true that occasional consonantal forms inconsistent with the accompanying vowels have survived—especially in the books least read by the Jews—and appear in the light of comparative grammar as indications of more primitive forms. These sporadic survivals show that the correction of obsolete forms was not carried through with perfect consistency; but we are never safe to argue as if we possessed the original form of the texts.

In the Pentateuch, for example, the form אָנֹכִי stands not only for אָנֹכִי (3d personal pron. masc.) but for אָנֹכִי (the feminine). And hence a favourite argument was אָנֹכִי for the superior antiquity of this part of the Old Testament. But the same thing is found elsewhere (Frensdorff, *Mass. Wörterb.*, p. 233), especially in Babylonian codices of the prophets (Geiger, *Urschrift*, p. 236; *Z. D. M. G.*, xxviii. 676). The feminine can never by any possibility have been pronounced *hu*, but the old orthography was probably אָנֹכִי for *hu* and *hi* alike (Nöldeke in *Bibel-Lexikon*, *ut supra*, after Levy).

The chief historical changes in the Hebrew language which we can still trace are due to Aramaic influence. The Northern Israelites were in immediate contact with Aramaean populations and some Aramaic loan-words were used, at least in Northern Israel, from a very early date. At the time of Hezekiah Aramaic seems to have been the usual language of diplomacy spoken by the statesmen of Judah and Assyria alike (2 Kings xviii. 26). After the fall of Samaria the Hebrew population of Northern Israel was partly deported, their place being taken by new colonists most of whom probably had Aramaic as their mother-tongue. It is not therefore surprising that even in the language of Judea increasing signs of Aramaic influence

appear before the Exile.³ The fall of the Jewish kingdom accelerated the decay of Hebrew as a spoken language. Not indeed that the captives forgot their own tongue in Babylon, as older scholars supposed on the basis of Jewish tradition. The Exilic and post-Exilic prophets do not write in a lifeless tongue, and Hebrew was still the language of Jerusalem in the time of Nehemiah (ch. xiii.) in the middle of the 5th century B.C.⁴ But after the Exile the petty people of the Jews were in daily intercourse with a surrounding Aramaean population, and the Aramaic tongue, which was the official language of the western provinces of the Persian empire, began to take rank as the recognized medium of polite intercourse and letters even among tribes of Arabic blood—the Nabataeans whose inscriptions in the Hauran are written in Aramaic. Thus Hebrew as a spoken language gradually yielded to its more powerful neighbour, and the style of the latest Old Testament writers is not only full of Aramaic words and forms but largely coloured with Aramaic idioms, while their Hebrew has lost the force and freedom of a living tongue (Ecclesiastes, Esther, some Psalms, Daniel). The Chronicler no longer thoroughly understood the Old Hebrew sources from which he worked, while for the latest part of his history he used a Jewish Aramaic document, part of which he incorporated in the book of Ezra. Long before the time of Christ Hebrew was the exclusive property of scholars, and its further history is that of a merely literary language.

*The Literary Development of Hebrew.*⁵—The Semitic peoples possessed the art of writing and an alphabetical character from a date so remote as to be lost in the mists of antiquity. This character was formerly known as Phœnician, its invention being ascribed to that people (Tac., *Ann.*, xi. 14). In reality it was the common property of all Semitic nations between Assyria and Egypt—an alphabetic character in contact on the east and on the west with more complicated syllabic or hieroglyphic systems, from one or other of which it may possibly have been derived.

De Rouge's theory that the alphabet was derived by the Phœnicians from the Egyptian hieratic writing obtained much currency a few years ago (see ALPHABET), but has rather lost ground since the appearance in 1874 of the long expected *Mémoire sur l'origine Égyptienne de l'alphabet Phénicien*. See the criticism in Lagarde's *Symmetica*, p. 113 seq. A newer theory by Deecke (*Z. D. M. G.*, xxxi. 102 seq.) derives the alphabet from the cuneiform characters, and makes the Aramaeans its authors, for which there is ancient tradition in Pliny, Diodorus, and Clemens Alexandrinus. Deecke dates the invention from the 9th century B.C., when the Assyrians first established themselves in Aram. This is certainly wrong, for, apart from other arguments, the stone of Mesha is not a product of the first days of alphabetic writing. Against the derivation of the Semitic alphabet from any hieroglyphic system, see Levy, *Phönizische Studien*, i. 49 seq. The best comparative table of Semitic alphabets is that by Euting in the English translation of Bickell's *Outlines of Heb. Gram.* (Leipsic, 1877). On the history of Hebrew writing, especially in its bearing on the history of the Biblical text, see Wellhausen in Bleek's *Einführung*, 4th ed. (1878), with Nöldeke's remarks, *Z. D. M. G.*, xxxii. 691 seq.

This ancient alphabet consists of twenty-two consonants, of which one at least (*y*) stood in Hebrew for two distinct sounds, still separated in the Septuagint pronunciation. The vowels were supplied by the reader—which is not so difficult in Semitic languages, where vocalization constitutes no difference of root. In certain cases the weaker consonants served as *matres lectionis* to indicate cognate vowel sounds and preclude ambiguity of pronunciation; but in the old

³ Details in Ryssel, *De Elohister Pentateuchi Sermones*, (Leipsic, 1878), the most important collection of materials since Gesenius, *Geschichte der hebr. Spr. und Schrift* (1815).

⁴ An argument to the contrary drawn by Jewish interpreters from Neh. viii. 8 rests on false exegesis.

⁵ As we possess no books in classical Hebrew except the Old Testament, the reader is referred for several aspects of this topic to the sketch of the Old Testament literature in the article BIBLE.

¹ See Stade's essay on the relation of Phœnician and Hebrew, *Morgenländische Forschungen* (1875), with Nöldeke's criticism, *Z. D. M. G.*, xxix. 325; also the latter's article, "Sprache, hebräisch," in *Bibel-Lexikon*, v. 362 seq.

² Böttcher, *Lehrb. d. Hebr. Sprache* (1866), l. 13 seq.

writing, this usage was far less extensive than in our Hebrew MSS., and hardly applied except to diphthongs and to a,—or less often î, û—at the end of words.¹ This old character with its scanty indications of vowels continued to be used by the Hebrews throughout the flourishing period of their literature and for some time after the Exile, till at length they gradually adopted a newer form of letters (the square or, as the Talmud calls it, the Assyrian character) which was developed among the Aramæans and spread with the increase of Aramaic influence. Jewish tradition ascribes the introduction of the square character to Ezra (*Synh.* 21b 22a; Jerome, *Prolog. Gal.*); but the Samaritans, who did not receive the Pentateuch from the Jews till about 400 B.C., must have got it in the old letter which they still retain in a corrupted form. The square letter probably did not prevail till a good deal later, the earliest Jewish inscription in which it appears being of the date 176 B.C. (published by De Vogué, *Rev. Arch.*, 1864), while the coins of Judea retain the old character still later. The transformation was complete before the time of Christ, for Mat. v. 16 alludes to the new form of *Yod* (jet).² By this time too the use of *matres lectionis* must have become more ample. The later introduction of vowel points and accents belongs to the history of the study of Hebrew as a dead language. The forms of the old Semitic alphabet are most suitable to be cut on stone, and indicate a special adaptation for monumental inscriptions (*cf.* the two tables of the Decalogue). Between the beginnings of such inscriptions and the general use of writing for literary purposes a considerable period might intervene. The earliest products of Hebrew authorship seem to have been lyrics and laws, which would circulate in the first instance from mouth to mouth without the use of written copies. We have notice of early written collections of lyrics prior to our present historical books—the *Book of the Wars of Jehovah* (*Num.* xxi. 14) and the *Book of Jashar* (*Josh.* x., 2 *Sam.* i.). We have no clue to the age of the former book, but the lines quoted from it are plainly of great antiquity. The *Book of Jashar* is not earlier than the time of Solomon; for a fragment from it referring to the building of the temple has been recovered from the Septuagint of 1 *Kings* viii. (Wellhausen in Bleek, *ut supra*, p. 236). The earliest date of written law books is uncertain. It may fairly be made a question whether Moses left in writing any other laws than the commandments on the tables of stone. Even Ex. xxiv. 4 and xxxiv. 27 may in the original context have referred to the ten words alone. And it is certain that ancient law was handed down by oral tradition and local custom to a much later date. The prophets frequently allude to the oral decisions of the priests as a source of law, and the practice of appealing to the local customs of certain towns is alluded to in 2 *Sam.* xx. 18 (as restored by Ewald from the LXX.)—"Ask at Abel and at Dan whether the genuine old statutes of Israel have lost their force." In like manner the story of the early fortunes of the nation down to the time of David often presents characteristics which point to oral tradition as its original source. Yet written history began comparatively early. A scribe was attached to the royal court from the reign of David downwards; and the older parts of the books of Samuel, which must have been written not long after the time of that king (see

DAVID), are framed in a masterly style, which shows that the art of composition in prose was already thoroughly understood. So too the best written and most brilliant part of the narrative of the Pentateuch—the combined history of the Jehovist and the non-Levitical Elohist—appears to be unquestionably earlier than the rise of prophetic literature in the 8th century B.C. In this narrative—itsself the product of more than one writer—are included several collections of old laws, so that we have between the time of David and the age of Amos and Hosea a flourishing historical and legal literature, in which and in lyrical collections like the *Book of Jashar* were embodied many poems, legends, and other remains, transmitted, whether orally or by writing, from a much earlier date. To the same period may be assigned the most interesting and graphic histories in the book of Kings, the splendid episode of Elijah, and other remains of Ephraïtic history; and to these must probably be added the main stock of the Song of Solomon, though this lyric drama has suffered much from interpolation, and presumably was not written down till a comparatively late date and from imperfect recollection, so that its original shape is very much lost. It is mainly from the admirable prose narratives, to which nothing in later books can be compared, that we must judge of the first bloom of Hebrew literature under the ancient kingdoms of Judah and Ephraim, before the convulsions that accompanied the advance of Assyria and prior to the influence of written prophecy. It is a literature eminently fresh and vivacious, full of exact observation of nature and of men, always drawing directly from life, and working on the reader not by elaborate description but by dramatic presentation of character and action. The authors are too intent upon the story to interpose their own comments or point a moral, but they tell their tale with sympathy and often with an undercurrent of dry humour. It can hardly be said that the writings of this period have a specifically religious purpose. Reflecting with admirable veracity the actual life of the nation they are full of the relation between Israel and Jehovah, because that relation was constantly present to the people as a very real fact without which the history could not be told. It is to this circumstance that we owe the preservation of so large a mass of early prose, which was taken over and incorporated in their works by later historians who wrote with a distinctly religious purpose; while on the other hand the early lyric collections have disappeared, all but a few fragments, presumably because their tone was prevailingly secular. That the Hebrews once possessed a poetry of high merit drawn from the themes of ordinary life appears, not only from the book of Canticles and such relics as the Song of the Well (*Num.* xxi. 17, 18), but from the names of popular airs preserved in the titles of the Psalms. Thus we learn from Isa. lxxv. 8 that the title *Al-Taschîth* (*Ps.* lvii.) is taken from a vintage song of which the first line was "Destroy it not, for a blessing is in it." These popular songs, then, survived the Exile and long continued to live in the mouths of the people. But they were without interest to the later guardians of Israel's literature, and fell into oblivion when Hebrew ceased to be the vernacular of the nation. A last echo of the festal songs of the Jewish maidens in the Talmud (*Mishna Ta'anit*, iv. 8, and the corresponding Gemara) shows only the total decay of the popular muse.

In this earliest period—the age of popular literature, as we may call it, modelled upon the songs and histories that circulated orally through the country—there is a remarkable preponderance of writings connected with the northern kingdom, and these include the narratives that are fullest of human interest and the poetry richest in colour and imagination, such as the loves of Jacob and Rachel, the history of Joseph, the life of Elijah, the pictures of nature

¹ The stone of Mesha is the earliest evidence. Lagarde, *Griech. Uebers. d. Proverbien* (1863), p. 4, observed that the LXX. translated from a Hebrew copy without *matres lectionis*. This is put rather too barely, but is very near the truth. Compare Wellhausen, *ut supra*, and *Text der BB. Samuelis* (1871); Nöldeke, *Z. f. Wissensch. Theol.* (1873), p. 120; Chwolson in *Travaux de la 3^{me} section du Congrès international des Orientalistes*, pt. ii.

² A papyrus of the British Museum, showing the square letter as it was written in Egypt a little before the time of Christ, has been facsimiled by the Palæographical Society (*Or. Ser.*, 1877).

in the Canticles. The political and social superiority of Ephraim before the conflict with Assyria is reflected in the literature. A new epoch begins with the rise of written prophecy in the 8th century. By this time writing and literary knowledge were widely diffused (Isa. viii. 1; xxx. 8; x. 19).¹ Amos, himself an excellent stylist, in whose book only perverse ingenuity can trace marks of rusticity ("imperitum sermone," says Jerome), was a simple herdsman in the wilderness of Judah. Yet it appears that the origin of written prophecy was due less to the spread of education than to the rise of a new school of men whose whole method and aims were in conflict with the official prophetic societies, the unworthy successors of Samuel and Elijah.

In the terrible struggle with Nineveh, when the kingdom of Ephraim perished and Judea seemed lost beyond hope, the new prophecy, clear of vision when all were blinded, calm in its unshaken faith of ultimate victory, and pursuing with unflinching steadfastness a great purpose of righteousness, established a spiritual and intellectual ascendancy which is stamped on the whole literature of the Assyrian and Chaldean periods. In the book of Deuteronomy the ancient ordinances of Israel were rewritten in the prophetic spirit, and the reformation carried out by Josiah on the basis of this book is the decisive proof of the influence of the written word as the organ of prophetic ideas. The same influence can be traced in other directions,—in psalms that express the type of individual faith, and in the historical books as they were finally shaped after the fall of Jerusalem, when the old popular narrative was filled out and continued in a spirit of prophetic pragmatism, and with the direct object of enforcing prophetic teaching. The Exile, which robbed Israel of every other inheritance, gave increased value and authority to the written word, and in the author of Isa. xl.—lxvi. we find a prophet who no longer appears in person before his audience but does his whole work by the pen. There are other short prophecies of the Babylonian age, as Isa. xiii., xiv., which seem to have been first published as anonymous broadsides—a characteristic change from the method of the former prophets, who wrote only what they had first spoken to the people. The earliest written prophecy is nervous rhetoric of the old pregnant Hebrew style interspersed with bursts of song. Even before the Exile this style had undergone a change; the prophecies of Jeremiah have lost something of the old force, while they display a subtler habit of reflexion and a pathos which has its origin in the conflict of a sensitive and shrinking temperament with the overpowering sense of prophetic duty. Jeremiah was much occupied with the dark problems of providence and the meaning of the sufferings of the faithful in Israel, a topic which goes beyond the sphere of the earlier prophecy, but forms a chief theme of Isa. xl.—lxvi., and from a different point of view is taken up and discussed in the book of Job. The last-named book is the highest utterance of another characteristic form of Hebrew literature, the Chokma, that is, wisdom or practical philosophy in parabolic, epigrammatic, and poetic form. The earliest distinct trace of literary cultivation of this philosophy, which from its nature must at first have passed unwritten from mouth to mouth, is the collection of ancient proverbs by scholars in the service of Hezekiah (Prov. xxv. 1). Along with the simple epigrammatic proverbs which continued to be a favourite vehicle of Jewish thought long after Hebrew had given way to Aramaic, the earliest form of Hebrew wisdom seems to have been the fable about plants and trees (Jud. xi., 2 Kings xiv. 9, cf. 1 Kings iv. 33), so different from the animal fables of Kalilag and

Damnag or Sindban, which the later Semitic literature borrowed from India. The further development of the Chokma ran parallel with the progress of prophecy, and though it is generally maintained that Jeremiah quotes the book of Job, it is perhaps more likely that the contrary is the case, and that the latest and most meditative phase of prophecy was absorbed into the poetry of the Chokma. The brief revival of spoken prophecy after the Exile lacks the old fire, and presents no notable literary feature except the use of somewhat fantastic symbolic imagery, the prototype of the later apocalyptic literature.

The decadence of prophecy and the synchronous systematization of the ceremonial law on lines first drawn by Ezekiel, mark the commencement of the third and last period of Hebrew literature. The age of religious productivity was past, and the narrow limits and political nullity of the new Jewish settlement under the Persians presented no favourable conditions for a fresh development of truly national literature. The scribes took the place of the prophets, and the growth of traditionalism imposed increasing restrictions on original thought. The freshest and best products of this period are the post-Exile psalms, the hymns of the second temple, which occupy a large part of the Psalter, and, though generally inferior to the older lyrics in the highest poetical qualities, are often full of the charm of genuine feeling and sweet utterance, and sometimes rise to a sublime energy of devotion and faith. With these psalms the graceful prose idyll of Ruth has a natural affinity. The other writings of the last age are on the whole much inferior. As the language decayed, the graces of the older prose style were lost. The memoirs of Ezra and Nehemiah, the colourless narrative of the Chronicles, and even the book of Esther, are singularly destitute of literary merit.

Yet letters were sedulously cultivated. The *Midrash*, or sermonizing treatment of the old history which holds so large a place in later Jewish literature, had come in before the time of the Chronicler, who quotes a work of the kind by name—the *Midrash of the Book of Kings* (2 Chron. xxiv. 27, cf. xiii. 22). Along with this came the beginnings of Haggada, the formation of parables and tales attached to historical names, of which the book of Jonah is generally taken as an early example, and which attains much greater dimensions in the apocryphal additions to the Hagiographa. And so at the close of the Old Testament period the author of Ecclesiastes could speak of the weariness of much study and the endless sterility of bookmaking. His judgment was confirmed by posterity, for of these many books scarcely a trace remains.

*The Cultivation of Hebrew as a Dead Language.*²—We have seen that when the latest books of the Old Testament were written Aramaic had already supplanted Hebrew as the language of common life. But the knowledge of the ancient idiom was kept alive not merely by the study of the sacred books but by the continued use of Hebrew for literary purposes. Several books of the Apocrypha appear to be translated from Hebrew originals—Sirach, Judith, 1 Mac.—the last according to the express testimony of Jerome. It is even probable that the Old Testament canon contains elements as late as the epoch of national revival under the Maccabees (Daniel, certain Psalms), for Hebrew was the language of religion as well as of scholarship. As for the scholars, they affected not only to write but to speak in Hebrew; but they could not resist the influence of the Aramaic vernacular, and indeed made no attempt to imitate

² On this topic compare in general Wolf's *Bibliotheca Hebraea*, 1715–1733; Bartoloci's *Bibliotheca Magna Rabbinica*, 1675–1693; Imbonati's *Bibliotheca Latino-Hebraica*, 1694; Diestel, *Geschichte des A. T. in der Christlichen Kirche*, 1869; R. Simon, *Histoire Critique du V. T.*, 1678.

¹ In the 7th century written instruments were used in sales of property (Jer. xxxi. 10), and in divorce cases they are recognized in Deut. xxiv. 1.

the classical models of the Old Testament, which neither furnished the necessary terminology for the new ideas with which they operated, nor offered in its forms and constructions a suitable vehicle for their favourite processes of legal dialectic. Thus was developed a new scholastic Hebrew, "the language of the wise" (לשון חכמים), preserving some genuine old Hebrew words which happen not to be in the Bible, and supplying some new necessities of expression by legitimate developments of germs that lay in the classical idiom, but thoroughly interpenetrated with foreign elements and as little fit for higher literary purposes as the Latin of the mediæval schoolmen. The chief monument of this dialect is the body of traditional law called the Mishna, which is formed of materials of various dates, but was collected in its present form about the close of the 2d Christian century. The doctors of the subsequent period still retained some fluency in the use of Hebrew, but the mass of their teaching preserved in the Gemara is Aramaic.¹ The language of the Mishna has been described by Geiger, *Lehr- und Lesebuch zur Sprache der Mischnah* (Breslau, 1845); L. Dukes, *Die Sprache der Mischna* (Esslingen, 1846) and *Zur rabbinischen Sprachkunde* (Vienna, 1851); J. H. Weiss, *Mishpat L'shôn ham-Mishna* (Vienna, 1867).

During the Talmudic period nothing was done for the grammatical study of the old language, but there was a traditional pronunciation for the synagogue, and a traditional interpretation of the sacred text. The earliest monument of Jewish interpretation is the Septuagint, but the final form of traditional exegesis is embodied in the Targums or Aramaic paraphrases, especially in the more literal Targums of Onkelos and Jonathan, which are often cited by the Talmudic doctors. Many things in the language of the Old Testament were already obscure, and the meaning of words was discussed in the schools, sometimes by the aid of legitimate analogies from living dialects,² but more often by fantastic etymological devices such as the *Notarikon*, or use of analogies from shorthand.

The real service rendered to Hebrew philology by the Talmudic doctors consists not in what they produced but in the knowledge which they preserved from the time when the idiom of the Old Testament was a living tongue. The exaggerated value which their casuistic exegesis attached to every syllable and every letter of the sacred books resulted in a final preservation, not indeed of the original text, but of the text which had become authoritative, and which is hardly later than the 1st Christian century. And fortunately for later scholarship the period immediately subsequent to the close of the Talmud (about 600 A.D.) devised in the vowel points and accents a means for preserving not merely the consonants of this text but the exact pronunciation and intonation of the synagogue. The idea of this system of punctuation appears to have been taken from a similar usage adopted in Syriac MSS.; the complete development of the idea as we find it in our present Hebrew Bibles must have been reached by successive steps which we cannot now trace. The current punctuation is the work of the Palestinian schools; another system resting on the same foundations was developed in Babylon, and is known from the MSS. of the Petersburg library collected by Firkowitsch, and also from copies brought from Yemen. The difference between the two systems lies more in the notation than in the pronunciation, and neither punctuation can claim absolute priority.³ The work of the punctuators

¹ See Bacher, *Die Aggada der Babylonischen Amoräer* (Strasbourg, 1879), for many illustrations of the Hebrew scholarship of the Gemarists.

² See B. Rosh hash-Shana, 26b; Delitzsch on Ps. lv. 23 and Isa. xiv. 23.

³ The Babylonian punctuation can be best studied in Strack's facsimile (St Petersburg, 1876) of the St Petersburg codex of the prophets of 916 A.D. Notable in this system is the absence of a sign for sehhol

was perhaps completed in the 7th century. After a time the vowel signs came to be thought as old as the text, but a juster view was revived by Elias Levita (1472-1549),⁴ and, after the great controversy in the 16th century between Cappellus and Buxtorf, finally gained universal recognition.⁵ With the work of the punctuators is associated the collection by the Massorets of a great mass of notes designed to preserve and illustrate by statistics exceptional phenomena of the Old Testament text,⁶ a work which may be viewed as the first step towards scientific study of Hebrew philology.

With all this the old traditional scholarship continued to decline till the 10th century, when a revival of Hebrew study under the influence of Mahometan learning took place among the Arabic-speaking Jews (Saadia of the Fayyum, Menahem ben Sarug, &c.).⁷ Then, early in the 11th century, came the acknowledged fathers of mediæval Jewish philology,—the grammarians Judah surnamed Hayyug, discoverer of the system of triliteral roots,⁸ and the lexicographer Abulwalid Merwân ibn Ganâh (Rabbi Jouah), who made excellent use of Arabic analogies as well as of the traditional material.⁹ A succession of able scholars continued their work, of whom the most famous are Abraham ben Meir of Toledo, surnamed Ibn Ezra (1092-1167), a man of great originality and freedom of view; Solomon Isaaki of Troyes, called Rashi and sometimes by error Jarchi, i.e., of Lunel (died 1105), whose writings are a storehouse of traditional lore; and David Kimchi of Narbonne, called Radak (circ. 1200), whose commentaries, grammar, and lexicon exercised an enormous and lasting influence, and were the chief fountain of knowledge for the Christian Hebraists of the 16th century. Our own authorized version, for example, bears the stamp of Kimchi on every page.

On the Jewish scholars and their works consult Wolf and Bartolocci, also De Rossi, *Dizionario Storico degli Autori Ebrei*, Parma, 1802; on Ibn Ezra in particular, the *Introduction* to Friedländer's translation of his *Com. on Isaiah* (London, 1873), and the same writer's *Essays on the Writings of Ibn Ezra* (London, 1877); on the French Rabbins, *Histoire Lit. de la France*, vol. xvi., but especially vol. xxvii. (1877); on Rashi, Zunz's *Gesammelte Schriften*, iii. 100, and a biography by the same scholar, translated into German by Bloch (1840). In the later Middle Ages Jewish learning was cramped by a narrow Talmudical orthodoxy; but a succession of sound scholars held their ground till Elias Levita and others of his age transmitted the torch to the Christian universities.

Up to the revival of letters there was no productive Hebrew scholarship among Christians. In the Greek and Latin Church the few fathers who, like Origen and Jerome, knew something of the language were wholly dependent on their Jewish teachers, and have value for us only as depositaries of Hebrew tradition. Nor was it otherwise in the East. The Syriac version of the Old Testament is permeated

(2), which is replaced by *i* or *a*. See also Piinker's *Eint. in d. Babylonisch-heb. Punctuationssystem* (Vienna, 1863), and for other literature, Wellhausen-Bleek, p. 614, to which add Derenbourg, *Revue Critique*, June 21, 1879.

⁴ See his *Massoreth ham-Massoreth*, re-edited by Dr Ginsburg, 1867.

⁵ The history of the controversy has been written by G. Schnedermann, *Die Controverse des Ludovicus Cappellus mit den Buxtorfen* (Leipsic, 1879).

⁶ On the Massorah see especially Jacob b. Hayyim's preface to the Venice Rabbinical Bible (reprinted and translated by Dr Ginsburg, London, 1867), Levita's *Massoreth ham-Massoreth*, and Buxtorf's *Tiberias* (Basel, 1620). Besides the Massorah as printed by J. b. Hayyim in the Venice Bible, which is superior to all reprints, we have in print *Ochlah w'Ochlah* (ed. Frensdorff, Hanover, 1864), and the first part of the *Massorah Magna* (ed. Frensdorff, 1876). A new edition of the Bible with Massorah, from an extensive collation of MSS., is now being printed at Vienna by Dr Ginsburg.

⁷ The connecting link between the Massorets and the grammarians is Rabbi Aaron ben Mosheh ben Asher, whose *Dikduke hal-Tamim* has been published by Baer and Strack (Leips. 1879).

⁸ See his *Two Treatises*, edited by Nutt, London, 1870.

⁹ His *Book of Roots*, in Arabic, edited by Neubauer, Oxford, 1876.

by the influence of the synagogues where it is not guided by the Septuagint, and the homilies of Aphraates are a mine of Jewish tradition. In the Middle Ages some knowledge of Hebrew was preserved in the church by converted Jews and even by Christian scholars, of whom the most notable were the Dominican controversialist Raymundus Martini and the Franciscan Nicolaus de Lyra, through whose popular commentaries the exegesis of Rashi was conveyed to Luther and largely influenced his interpretation of Scripture.¹ But there was no continuous tradition of Hebrew study apart from the Jews, and in the 15th century, when the revival of independent scholarship kindled the desire to add a third learned tongue to Latin and Greek, only the most ardent zeal could conquer the obstacles that lay in the way. Orthodox Jews refused to teach those who were not of their faith, and on the other hand the bigotry of ignorant churchmen desired nothing better than the entire suppression of Jewish learning. Even books were to be had with the greatest difficulty, at least north of the Alps. In Italy things were somewhat better. Jews expelled from Spain received favour from the popes. Study was facilitated by the use of the Hebrew printing press, which was at work at Reggio as early as 1475, while the whole Hebrew Bible appeared at Soncino in 1488.² The cause of learning found its champion among the northern humanists in John Reuchlin (1455–1522), whose *Rudimenta* (Pforzheim, 1506) opened the door to students, while his victorious contest with Pfefferkorn and the Cologne obscurantists established the claim of Hebrew studies on scholarship and the church.

The new learning spread fast. Sebastian Münster in Heidelberg, and Paul Büchlein (Fagius) at Isny, Strasburg, and Cambridge, were worthy pupils of the famous and liberal Jewish scholar Levita. France drew teachers from Italy. Santes Pagninus of Lucca was at Lyons; and the trilingual college of Francis I. at Paris, of which Vatablus and Le Mercier soon became the ornaments, attracted among other foreigners Giustiniani, bishop of Nebbio, the editor of the Genoa Psalter of 1516. In Rome the Jewish convert Felix Pratensis taught by invitation of Leo X., whose name and that of the more famous convert J. b. Hayyim live mainly in connexion with the great Rabbinical Bibles that issued from the Bomberg press at Venice. In Spain, the old home of Jewish scholarship, Hebrew learning was promoted by Cardinal Ximenes, the patron of the Complutensian Polyglot. Printing presses were multiplied, and the great humanist printers, as Froben at Basel and Étienne at Paris, competed with Italy in the production of Hebrew books. In brief, before the middle of the 16th century the place of Hebrew studies was secure throughout learned Europe, while in Protestant countries opposition to the authority of the Vulgate combined with scholarly interest to make the study of the original text of Scripture appear indispensable. Thus in Scotland the establishment of a trilingual course in the universities is contemplated in the first *Book of Discipline*.³

For a time the best Christian scholars leaned mainly on

the Rabbins. But in the larger air of humanism a more independent type of learning soon arose, of which Le Mercier in the 16th and Drusius in the beginning of the 17th century may be taken as representatives. The importance of the ancient versions was recognized, and their study was fostered by the publication of the Polyglots.⁴

In the 17th century the cognate dialects were cultivated with great vigour and success by men like Selden, Castell, and Pococke in England, De Dieu in Holland, Bochart in France, Ludolf and Hottinger in Germany; and these studies bore fruit both for the Hebrew grammar and for the lexicon. Rabbinic learning was not forgotten, and found its chief ornament in the elder Buxtorf at Basel, who was also the author of grammars and a handy lexicon which long remained favourite manuals in England and on the Continent.⁴

At the same time a critical spirit arose, which involved Hebrew philology in the meshes of theological controversy. The battle as to the age of the vowel points has already been referred to. It was part of a larger question as to the integrity of the received Hebrew text, and the legitimacy of text criticism, which received dogmatic importance from the prevalence of extreme theories of verbal inspiration in the Protestant Church. Thus the Protestant Cappellus found his main support in the Catholic Church (Morinus, R. Simon), while the authority of the Massoretic text and punctuation was elevated to a dogma in the *Formula Consensus Helvetica* (1675), not without protest from the wiser Protestantism of France. The critical school had also its extravagances, and an undue depreciation of tradition was one of several false principles that it would be tedious to enumerate, which came into vogue in the latter part of the 17th century, and long continued to impede the progress of scientific Hebrew philology. In the beginning of the 18th century Semitic studies had their chief seat in Holland, where Albert Schultens took up the comparative method with fresh energy, and applied it to Hebrew on a scale which gave a new shape to the study of the language.⁵ Schultens laid emphasis on the limited extent of the Old Testament literature, which makes it an inadequate record of the phenomena of the Hebrew language, and proposed to supply these defects by a large use of the dialects, mainly of the Arabic, in which he had wide and accurate reading. His *Institutiones ad fundamenta Linguae Hebraeae* (1737) mark an advance on previous grammars, and in his commentaries is accumulated an enormous mass of material of the highest value for the lexicographer. Schultens founded an influential school, of which Schroeder was the chief ornament; but his method was easily abused, and fell into discredit in the hands of arbitrary expositors like Venema. After Holland, Germany became the chief seat of Hebrew studies. In Halle, where the influence of Francke directed special attention to Biblical learning, there sprang up contemporaneously with the Dutch school a school of Hebraists,—earnest, laborious, and thorough, but somewhat jejune and deficient in æsthetic sympathy,—of which the Michaelis family were the chief representatives. J. D. Michaelis (1717–1791) exercised a sort of sovereignty in Hebrew letters, and the stamp of Halle has left a permanent impress on the German schools, though a more sympathetic and emotional type of scholarship, beginning with Herder and Eichhorn, became dominant under the influence of Ewald.

⁴ To obtain an idea of the way in which Hebrew was taught in the 17th century one may read the *Diatriba* of Caspar Scioppius, in *H. Grotii et aliorum dissertationes de studiis instituentis* (Amst., 1645).

⁵ On Schultens, his method and school, see C. Sepp, *Johannes Stinstra en zijn Tijd* (Amst., 1865). The Dutch schools of the 16th and 17th centuries are well described by the same author, *Het godgeleerd Onderwijs in Nederland gedurende de 16de en 17de Eeue* (Leyden, 1873–74).

¹ See Siegfried's essay in Merx's *Archiv*, i. 428, ii. 38.
² De Rossi, *Annales Hebraeo-Typographici Sec. XVI.*, Parma, 1795. A lively picture of the difficulties that lay in the way of Hebrew study is found in the *Autobiography* (ed. Riggenbach, 1877) of Conrad Pellican, who contributed to Reisch's *Margaritha Philosophica* the first imperfect Hebrew grammar composed by a Christian (Strasburg, 1504, reprinted in facsimile by Nestle, Tübingen, 1877). See also Geiger's *Johann Reuchlin* (Leipzig, 1871). Reference may also be made to the same author's *Studium der Heb. Spr. in Deutschl. vom Ende des 15ten bis zur Mitte des 16ten Jahrhunderts* (Breslau, 1870), and Jourdain's *De l'enseignement de l'hébreu dans l'université de Paris* (1863).

³ The first Hebrew grammar published in Scotland is that of John Row, moderator of the school of Perth, and afterwards minister at Aberdeen, (Glasgow, 1644). The preface bears date 1637. With the grammar appeared a *Xilids Hebraica*.

By the epoch-making labours of Silvestre de Sacy (1758–1838), which first placed Oriental learning and especially Semitic grammar on a broad and thoroughly scientific footing, a new impulse was given to Hebrew philology, which since that time has moved with the advance of general Semitic studies, and can hardly again fall into deviant paths. The great teachers of Hebrew in the present century have been two Germans, Gesenius and Ewald,—the former excelling in method and lucidity of exposition, the latter in range of view and creative fertility of ideas. Among the direct or indirect disciples of these great scholars may be reckoned almost every Hebraist in Europe, and to them is mainly due the revival in England of a branch of learning which had almost become extinct through the prevailing dilettantism of last century.

Helps to the Study of Hebrew.—Grammars.—The principal modern methods are those of Gesenius, Ewald, and Olshausen. Gesenius's larger work, his *Lehrgebäude der hebräischen Sprache*, (Leipzig, 1817), is still useful for occasional reference. His smaller grammar has passed through innumerable editions, and in its most recent shape, as recast by Rödiger and finally by Kautzsch (1878), holds its ground as one of the best books for learners. Davies's version of Rödiger's Gesenius is the best of several English translations (1869–1876). The method of Gesenius is mainly empirical. Much more philosophic, but less simple and sometimes arbitrary in its refinements, is the *Ausführliches Lehrbuch* of Ewald (8th ed., Göttingen, 1870), of which the "Syntax" has been translated into English by Kennedy (1879). The shorter *Sprachlehre für Anfänger* (4th ed., 1874; Eng. trans. by Smith, 1870) is valuable but too difficult for ordinary beginners. Olshausen's *Lehrbuch* (Brunswick, 1861) is incomplete, the syntax having never appeared; but it is, on the whole, the best and most scientific exposition of the Hebrew grammatical forms. Two elementary grammars on Olshausen's system have been translated into English,—Bickell's *Grundriss* (Leipzig, 1869–1870; English by Curtiss, 1877) and Land's *Hebräisches Grammatica* (Amsterdam, 1869; English by Poole, 1876). The latter work has some peculiarities which detract from its utility, and neither Bickell nor Land supplies a proper syntax. Müller's *Schulgrammatik* (Halle, 1878) is also mainly on Olshausen's method with the addition of an excellent syntax. In English A. B. Davidson's *Introductory Hebrew Grammar* (3d ed., Edin., 1878) may be commended to beginners as a good practical method and easy introduction to the larger scientific grammars. Of other more extensive works may be named Böttcher's *Ausführliches Lehrbuch*, posthumously edited by Mühlau (Leipzig, 1866–68), a huge book serving as a sort of grammatical concordance to the Old Testament; Luzzatto's Italian *Grammatica* (Padua, 1853–69), which is valuable from the thorough Jewish scholarship of the author, the Latin grammar of Roorda, and in English the works of Kalisch (1862–63) and Green (New York, 1861). Among useful monographs on special points of grammar may be named Philippi, *Wesen und Ursprung des Status Constructus* (Weimar, 1871); S. R. Driver, *The Use of the Tenses in Hebrew* (Oxford, 1874); Giesebrecht, *Die Hebräische Präposition Lamed* (Halle, 1876); Davidson, *Outlines of Hebrew Accentuation* (1861). For comparative purposes, in the absence of a comparative system of the Semitic languages, which is hoped for from Renan, the hints in Wright's *Arabic Grammar* will be found most valuable.

Lexicons.—Far superior to all other lexicons is the *Thesaurus* of Gesenius, completed by Rödiger (Leipzig, 1829–1858). Gesenius published also a *Handwörterbuch*—of which the 8th ed. by Mühlau and Volek (Leipzig, 1877–78) contains a good deal of new matter not always improvement—and a *Lexicon Manuale* in Latin (2d ed. by Hoffmann, 1847), of which there is an English translation. The *Handwörterbuch* of Fürst (2d ed., 1863; Eng. trans. by S. Davidson, 1871; 3d ed. by Ryssel, 1876) proceeds on very faulty etymological principles and must be used with great caution. On Hebrew synonyms Pappenheim's *Yr'ot Sh'lo'moh* (1784–1811) is the principal work.

Concordances.—The *Concordantiae* of Buxtorf (1632) were reprinted by Beer (1863). Fürst's *Concordance* (1840) contains a good deal of supplementary matter, part of which is of little use. For the particles the (incomplete) concordance of Noldius (1679; ed. Tympius, 1734) is useful.

In addition to modern books the advanced student will sometimes find it useful to recur to older works, especially to the Jewish grammarians and lexicographers, but these need not be detailed here.

For the later Hebrew of the period of the Mishna, and for the new words and technical terms in the scholastic Hebrew of the Middle Ages, the best lexicon is Buxtorf's *Lexicon Chaldaicum Talmudicum et Rabbinicum* (1640). The recent reprint is not so good. A new lexicon by Levy has been in the course of publication since 1875 (*Neu-hebräisches und Chaldaisches Wörterbuch*). The

beginner will find the *Lexicon breve Rabbinico-philosophicum* appended to Buxtorf's small *Lexicon Hebraicum* very useful, and may also consult the treatises in Reland's *Analecta Rabbinica* (1702). In reading Rabbinical Hebrew it is well to have Selig's *Compendia Vocum Hebraico-Rabbinicarum* (1780). The similar work of Buxtorf is less full.

On the whole subject of this article consult Gesenius, *Geschichte der hebräischen Sprache und Schrift* (Leipzig, 1817); Renan, *Histoire générale des langues Sémitiques* (4th ed., Paris, 1864). (W. R. S.)

HEBREWS, EPISTLE TO THE. The New Testament writing usually known under this name, or less correctly as the Epistle of Paul the Apostle to the Hebrews, bears in the oldest MSS. no other title than the words Πρὸς Ἑβραίους, "To the Hebrews." This brief heading embraces the whole information as to the origin of the epistle on which Christian tradition is unanimous. Everything else—the authorship, the address, the date—was unknown or disputed in the early church, and continues to form matter of dispute in the present day. But as far back as the latter part of the 2d century the destination of the epistle "to the Hebrews" was acknowledged alike in Alexandria, where it was ascribed to Paul, and in Carthage, where it passed by the name of Barnabas, and no indication exists that it ever circulated under another title.¹ At the same time we must not suppose, as has sometimes been done, that the author prefixed these words to his original manuscript. The title says no more than that the readers addressed were Christians of Jewish extraction, and this would be no sufficient address for an epistolary writing (xiii. 22) directed to a definite circle of readers, a local church or group of churches to whose history repeated reference is made, and to which the author had personal relations (xiii. 19, 23). The original address, which according to custom must have stood on the outside of the folded letter, was probably never copied, and the early and universal prevalence of the present title, which tells no more than can be readily gathered from the epistle itself, seems to indicate that when the book first passed from local into general circulation its history had already been forgotten. With this it agrees that the early Roman Church, where the epistle was known about the end of the 1st century, and where indeed the first traces of the use of it occur (Clement, and *Shepherd of Hermas*), had nothing to contribute to the question of authorship and origin except the negative opinion that the book is not by Paul. Caius and the Muratorian fragment reckon but thirteen epistles of Paul; Hippolytus (like his master Irenæus of Lyons) knew our book and declared that it was not Pauline. These facts can hardly be explained by supposing that at Rome during the 2d century the book had dropped out of notice, and its history had been forgotten. Clement, Hermas, Hippolytus form a tolerably continuous chain, and the central Church of Rome was in constant connexion with provincial churches where, as we shall presently see, the epistle had currency and reputation. Under these circumstances an original trustworthy tradition could hardly have been lost, and it must appear highly questionable whether the author and address of the book were known at Rome even in the time of Clement. The earliest positive traditions of authorship to which we can point belong to Africa and Egypt, where, as we have already seen, divergent views were current by the end of the 2d century. The African tradition preserved by Tertullian (*De Pudicitia*, c. 20), but certainly not invented by him, ascribes the epistle to Barnabas. Direct apostolic authority is not therefore claimed for it; but it has the weight due to one who "learned from and taught with the apostles," and we are told that it had more currency among the churches than

¹ See the full refutation of supposed exceptions to the uniformity of this tradition in Zahn's article "Hebräerbrief" (*Herzog-Plitt, R. E.*, vol. v. p. 657).

“that apocryphal shepherd of the adulterers” (the Shepherd of Hermas). This tradition of the African Church holds a singularly isolated position. Later writers appear to know it only from Tertullian, and it soon became obsolete, to be revived for a moment after the Reformation by the Scottish theologian Cameron, and then again in our own century by the German critics, among whom at present it is the favourite view. Very different is the history of the Egyptian tradition, which can be traced back as far as a teacher of the Alexandrian Clement, presumably Pantæus (Euseb., *Hist. Eccl.*, vi. 14). This “blessed presbyter,” as Clement calls him, sought to explain why Paul did not name himself as usual at the head of the epistle, and found the reason in the modesty of the author, who, in addressing the Hebrews, was going beyond his commission as apostle to the Gentiles. Clement himself takes it for granted that an epistle to the Hebrews must have been written in Hebrew, and supposes that Luke translated it for the Greeks. Thus far there is no sign that the Pauline authorship was ever questioned in Alexandria. Origen rests on the same tradition, which he refers to “the ancient men.” But he knows that the tradition is not common to all churches. He feels that the language is un-Pauline, though the admirable thoughts are not second to those of the unquestioned apostolic writings. And thus he is led to the view that the ideas were orally set forth by Paul, but that the language, arrangement, and some features of the exposition are the work of a disciple. According to some this disciple was Clement of Rome; others named Luke; but the truth, says Origen, is known to God alone (Euseb., vi. 25, cf. iii. 38). It is not surprising that these limitations of the tradition had less influence than the broad fact that Origen accepted the book as of Pauline authority. From the time of Origen the opinion that Paul wrote the epistle became more and more prevalent in the East. In the West this view was still far from established in the 4th century. But it gained ground steadily; even those who, like Jerome and Augustine, knew the variations of tradition were unwilling to press an opposite view; and in the 5th century the Pauline authorship was accepted at Rome, and practically throughout Christendom, not to be again disputed till the revival of letters and the rise of a more critical spirit.

That the received view called for revision could not indeed be questioned when men began to look at the facts of the case. The vacillation of tradition and the dissimilarity of the epistle from the style and thoughts of Paul were brought out with great force by Erasmus in his concluding annotation on the book, where he ventures the conjecture based on a passage of his favourite Jerome, that Clement of Rome was the real author. Luther (who suggests Apollos) and Calvin (who thinks of Luke or Clement) followed with the decisive argument that Paul, who lays such stress on the fact that his gospel was not taught to him by man but by direct revelation (Gal. i.), could not have written Heb. ii. 3, 4, where the author classes himself among those who received the message of salvation from the personal disciples of the Lord on the evidence of the miracles with which God confirmed their word. The force of tradition seemed already broken, but the wave of reaction which so soon overwhelmed the freer tendencies of the first reformers brought back the old view. Protestant orthodoxy again accepted Paul as the author, and dissentient voices were seldom heard till the revival of free Biblical criticism in last century. As criticism strengthened its arguments, theologians began to learn that the denial of tradition involves no danger to faith, and at the present moment, in spite of the ingenious special pleading of Hofmann (*Die Heilige Schrift N. Ts.*, vol. v., Nördlingen, 1873), scarcely any sound scholar will be found to accept Paul as the direct author of the epistle, though

such a modified view as was suggested by Origen still claims adherents among the lovers of compromise with tradition.

The arguments against the Alexandrian tradition are in fact conclusive. It is probably unfair to hamper that tradition with Clement's notion that the book is a translation from the Hebrew, a monstrous hypothesis which has received its *reductio ad absurdum* in the recent attempt of J. H. R. Biesenthal to reconstruct the Hebrew text (*Das Trostschriften des Apostels Paulus an die Hebräer, kritisch wiederhergestellt, &c.*, Leipzig, 1878). But just as little can the Greek be from Paul's pen. The un-Pauline character of the style, alike in the words used and in the structure of the sentences, strikes every scholar as it struck Origen and Erasmus. The type of thought is quite unique. The theological ideas are cast in a different mould; and the leading conception of the high priesthood of Christ, which is no mere occasional thought but a central point in the author's conception of Christianity, finds its nearest analogy not in the Pauline epistles but in John xvii. 10. The Old Testament is cited after the Alexandrian translation more exactly and exclusively than is the custom of Paul, and that even where the Hebrew original is divergent. Nor is this an accidental circumstance. There is every appearance that the author was a Hellenist whose learning did not embrace a knowledge of the Hebrew text, and who derived his metaphysic and allegorical method from the Alexandrian rather than the Palestinian schools.¹

The force of these arguments can be brought out only by the accumulation of a multitude of details too tedious for this place, but the evidence from the few personal indications contained in the epistle is easily grasped and not less powerful. The argument from ii. 3, 4, which appeared decisive to Luther and Calvin, has already been referred to. Again, we read in xiii. 19 that the writer is absent from the church which he addresses, but hopes to be speedily restored to them. This expression is not to be understood as implying that the epistle was written in prison, for xiii. 23 shows that the author is master of his own movements.² The plain sense is that his home is with them, but that he is at present absent, and begs their prayers for a speedy return. But Paul, if he could say that he had a home at all, had it not in a community of Jewish Christians. The external authority of the Alexandrian tradition can have no weight against such difficulties. If that tradition was original and continuous, the long ignorance of the Roman Church and the opposite tradition of Africa are inexplicable. But no tradition was more likely to arise in circles where the epistle was valued and its origin forgotten. In spite of its divergencies from the standard of Pauline authorship, the book has manifest Pauline affinities, and can hardly have originated beyond the Pauline circle, to which it is referred, not only by the author's friendship with Timothy (xiii. 23), but by many unquestionable echoes of the Pauline theology, and even by distinct allusions to passages in Paul's epistles.³

In an uncritical age these features might easily suggest Paul as the author of a book which was read in MSS.

¹ For the Alexandrian elements in the epistle consult the list of passages in Hilgenfeld's *Einleitung* (Leipzig, 1875), p. 384, note. A large mass of valuable material is collected in J. B. Carpov's *Sacra Exegetica in Ep. ad Heb. ex Philone Alexandrino* (Helmstadt, 1750).

² In x. 31 the true reading is not “of me in my bonds,” but “on them that were in bonds,” τοῖς δεσπομένοις συνεπαθήσατε. The false reading, which was that of Clement of Alexandria, is probably connected with the tradition that Paul is author.

³ An unambiguous proof that our author had read the epistle to the Romans seems to lie in x. 30. This is the one Old Testament citation of the epistle which does not follow the Septuagint (Deut. xxxii. 35); but it is word for word from Rom. xii. 19. Further signs of dependence on Romans and Corinthians (which require sifting) have been collected by Holtzmann in Schenkel's *Bibel-Lexikon*, ii. 620, and Hilgenfeld's *Zeitschrift*, ix. 4 seq.

immediately after the recognized epistles of that apostle, and which contained nothing in its title to distinguish it from the preceding books with similar headings, "To the Romans," "To the Corinthians," and the like.¹ A similar history, as Zahn has pointed out, attaches to the so-called second epistle of Clement to the Corinthians.

When we see that the tradition which names Paul as author does not possess an authentic historical basis, we are necessarily carried on to deny historical authority to the subsidiary conjectures or traditions which speak of Luke and Clement of Rome. The history of the Alexandrian tradition shows that these names were brought in merely to lessen the difficulties attaching to the view that Paul wrote the book exactly as we have it. The name of Luke seems to be a conjecture of the Alexandrian Clement, for it has no place in the tradition received from his master. And Origen attaches no importance to either name. Some had mentioned one, and some the other, but God alone knows the truth. We have no reason to think more highly of these suggestions than Origen did. Indeed, no Protestant scholar now proposes the name of Clement, whose extant epistle to the Corinthians shows his familiarity with the epistle to the Hebrews, and at the same time excludes the idea that he composed it. The name of Luke has still partisans—most notably Delitzsch, who has carefully collected linguistic parallels between our epistle and the Lucan writings (*Commentar zum Hebräerbrief*, Leipsic, 1857; English translation, Edinburgh, 1868-70). The arguments of Delitzsch are generally met with the objection that our author must have been a born Jew, which from his standpoint and culture is in the highest degree probable, though not perhaps absolutely certain. In any case we cannot suppose that Luke wrote the epistle on Paul's commission, or that the work is substantially the apostle's; for such a theory takes no account of the strongly-marked individuality of the book in thought and method as well as expression. And the theory that Luke was the independent author of the epistle (Grotius and others) has no right to appeal to antiquity, and must stand entirely on the very inadequate grounds of internal probability afforded by language and style.

If Alexandria fails us, can we suppose that Africa preserved the original tradition? This is a difficult question. The intrinsic objections to authorship by Barnabas are not important. The so-called Epistle to Barnabas was not written by our author, but then it is admittedly not by Barnabas. The superior elegance of the style of our epistle as compared with that of Paul is not inconsistent with Acts xiv. 12; nor is there, as we shall see presently, any real force in the once favourite objection that the ordinances of the temple are described with less accuracy than might be looked for in Barnabas, a Levite and one who had resided in Jerusalem. On the other hand it is hard to believe that the correct account of the authorship of our book was preserved only in Africa, and in a tradition so isolated that Tertullian seems to be its only independent witness. How could Africa know this thing and Rome be ignorant? Zahn, who is the latest exponent of the Barnabas hypothesis, argues that in the West, where the so-called epistle of Barnabas was long unknown, there was nothing to suggest the idea of Barnabas as an author; that the true tradition might perish the more readily in other parts of the church after the name of Barnabas had been falsely attached to another epistle dealing with the typology of the ceremonial law; and finally, that the false epistle of

Barnabas, which was first so named in Alexandria, may there have carried off the true title of the epistle to the Hebrews after the latter was ascribed to Paul. That is not plausible, and it is more likely that an epistle which calls itself *λόγος παρακλήσεως* (Heb. xiii. 22) was ascribed to the *υἱὸς παρακλήσεως* (Acts iv. 36) in the same way as Ps. cxvii. was ascribed to Solomon, "the beloved of the Lord" (2 Sam. xii. 24, 25), from the allusion cxvii. 2, than that this coincidence of expression affords a confirmation of the Barnabas hypothesis. In short, the whole tradition as to the epistle is too uncertain to offer much support to any theory of authorship, and if the name of Barnabas is accepted it must stand mainly on internal evidence.

Being thus thrown back on what the epistle itself can tell us, we must look at the first readers, with whom, as we have already seen, the author stood in very close relations. It is generally agreed that the church addressed was composed of Hebrews or Christians of Jewish birth. We are not entitled to take this simply on the authority of the title, which is hardly more than a reflexion of the impression produced on an early copyist. But it is plain that the writer is at one with his readers in approaching all Christian truth through the Old Testament. He and they alike are accustomed to regard Christianity as a continuous development of Judaism, in which the benefits of Christ's death belong to the ancient people of God and supply the shortcomings of the old dispensation (iv. 9; ix. 15; xiii. 12). With all the weight that is laid on the superiority of Christianity, the religion of finality, over Mosaism, the dispensation which brought nothing to its goal, the sphere of the two dispensations is throughout treated as identical, without any allusion, such as could hardly have been avoided in addressing a Gentile church, to the way in which strangers and foreigners (Eph. ii. 19) had been incorporated with the people of God. Schürer indeed (*Stud. u. Krit.*, 1876, p. 776) has sought such an allusion in vi. 1, 2, where faith in God and belief in the resurrection and the judgment, points common to Judaism and Christianity, are reckoned to the elementary doctrine of Christ; and he concludes that the readers addressed were Gentile converts of a Judaizing type. But taken with the context these verses imply only that the Hebrews required to be warned against losing hold even of these first principles of revealed truth which lie in the Old Testament (v. 12). From all this we are not perhaps entitled to conclude that the church addressed contained no Gentile members, but it is plain that they were not sufficiently numerous and independent in their way of thought to affect the general type of Christianity in the community. To some writers the emphatic "all" in xiii. 24, the admonitions x. 25, xiii. 17, have suggested the possibility that the Hebrews addressed were but part, and a somewhat discontented part, of a larger community in which Gentile elements has a considerable place. But this appears a strained conclusion (Phil. iv. 21; 1 Th. v. 26) distinctly contrary to the general tone of the epistle, which moves altogether outside of the antithesis between Jewish and Gentile Christianity. We must think not of a party but of a church, and such a church can be sought only in Palestine or in one of the great centres of the Jewish dispersion. That the epistle was addressed to Palestine, or more specifically to Jerusalem, has been a prevalent opinion from the time of Clement of Alexandria, mainly because it was assumed that the word Hebrews must naturally mean Jews, whose mother-tongue was Aramaic. But the term has this restricted sense only when put in contrast to Hellenists. In itself, according to ordinary usage, it simply denotes Jews by race, and in Christian writings especially Jewish Christians. And there are several things in the epistle that seem to exclude Palestine, and above all Jerusalem. The Hellenistic cul-

¹ The place of the epistle in MSS. varies. The order of our Bible is that of the Latin Church, the oldest Greek codices placing it before the pastoral epistles. But the Latin order, which expresses the original uncertainty of the Pauline tradition, was formerly current even in the East.

ture of the writer and the language in which he writes furnish one argument. Then the most marked proof of Christian love and zeal in the church addressed was that they had ever been assiduous in ministering to the saints (vi. 10). This expression may conceivably have a general sense (1 Cor. xvi. 15?), but it is far more likely that it has the specific meaning which it generally bears in the New Testament, viz., the collection of alms for the church in Jerusalem. At any rate it was clearly understood in the first age of Christianity that the Judæan Church took alms and did not give them, receiving in temporal things an acknowledgment for the spiritual things they had imparted (Rom. xv. 27). In fact the great weight laid in the epistles of Paul on this—the only manifestation of the catholicity of the church then possible (Gal. ii. 10)—alone explains the emphasis with which our author cites this one proof of Christian feeling. Again, the expressions in ii. 3 already referred to imply that the readers did not include in their number direct disciples of Jesus, but had been brought to Christ by the words and miracles of apostolic missionaries now dead (xiii. 7). This conversion, as it appears from x. 32, was a thing of precise date immediately followed by persecution (note the aorists *φωτισθέντες—ὑπεμείνατε*); so that we cannot think of a second generation in the Palestinian Church, but are referred to some part of the Diaspora. Against these difficulties, which have led some of the latest defenders of the Palestinian address, as Grimm (who, in Hilgenfeld's *Zeitschr.* 1870, proposes Jamnia) and Moulton (*New Testament Commentary for English Readers*, vol. iii., 1879), to give up Jerusalem altogether, while others, as Riehm, suppose that the Hellenists of Jerusalem (Acts vi. 1) are primarily addressed, it is commonly urged that the readers are exposed to peculiar danger from the persecutions and solicitations of unbelieving Jews, that they are in danger of relapsing into participation in the Jewish sacrifices, or even that they appear to have never ceased to follow the ceremonial observances that had their centre in the temple ritual. The capital argument for this is drawn from xiii. 13, where the exhortation to go forth to Jesus without the camp is taken as an injunction to renounce fellowship with the synagogue and with the ceremonies and ritual of Judaism. But this exegesis rests on a false view of the context, which does not include verse 9, and expresses by a figure that Christians (as the priests of the new covenant) have no temporal advantage to expect by their participation in the sacrifice of Christ, but must be content to share his reproach, renouncing this earthly country for the heavenly kingdom (cf. xi. 16, 25–27 with xiii. 14; Phil. iii. 20). Altogether, this view of the situation of the first readers of the epistle appears distorted or exaggerated. It is obvious that our Hebrews were familiar with the law, and had a high regard for the ordinances of temple worship. In particular it appears that they had not fully understood how the mediatorial functions of the Old Testament were superseded by the mediatorship of Christ. But their ritualism seems to have been rather theoretical than practical. Had they been actually entangled in the daily practice of superseded ordinances, the author, whose insight into the true worth of these ordinances is clear, and whose personal relations to the Pauline circle are obvious, could hardly have been so nearly one of themselves as appears in xiii. 19, and at any rate could not have failed to give an express precept on the subject. But, on the contrary, he is in thorough sympathy with the type of doctrine on which their church was formed (xiii. 7); the easy way in which he touches on the "meats and drinks and divers washings" of Judaism seems to show that on this head he could count on carrying his readers along with him; and xiii. 9 hardly refers to sacrifices or to Levitical laws of clean and unclean, but

rather to some such form of asceticism (cf. ver. 4) as is spoken of in Rom. xiv. Nowhere does our author speak a warning against participation in sacrifices; nowhere does he touch on the burning questions that divided the Pharisaic Christians of Jerusalem from the converts of Paul. The practical lesson which he draws from his doctrine is that his readers ought to use with diligence the specifically Christian way of access to God (x. 19 seq.); and the only positive fault which he mentions in this connexion is a disposition to neglect the privilege of social worship (x. 25). This again is plainly connected, not with an inclination to return to the synagogue, but with a relaxation of the zeal and patience of the first days of their Christian profession (vi. 4 seq.; x. 32 seq.; xii. 1 seq.), associated with a less firm hold than they once had of the essentials of Christian faith, a less clear vision of the heavenly hope of their calling (iii. 12; iv. 11; v. 12). The apostle fears lest they fall away not merely from the higher standpoint of Christianity into Judaizing practices, but from all faith in God and judgment and immortality (iii. 12; vi. 1 seq.).¹

For the solution of the problem of the epistle it is of the highest importance to form an exacter conception of the causes and nature of this unhealthy condition of the church. Their first conversion had been followed by direct persecution, which their faith had triumphantly overcome. But these days were long gone by (x. 32). It does not appear that a like severity of trial had again fallen upon them. But there were persecutions at least in other parts of the church (xiii. 3, 23). The times were troubled, and from day to day there were many trials and many reproaches to sustain. The dull and long-continued strain of conflict with surrounding wickedness was harder to bear than a sharp onslaught of the enemy (ch. xii.). They were weary of enduring, weary of hope deferred, and so the bonds of their Christian unity were loosened, their brotherly love weakened (xiii. 1 seq.), and they began to doubt the verity of those heavenly good things which their first faith had so vividly realized. In such circumstances it was natural that the writer should lay stress on the contrast between the eternal and the transitory, the things of faith and the things of sight, the heavenly Zion and the earthly pilgrimage. But the remarkable feature of the epistle is that this contrast is drawn out in the form of a threefold argument to show the superiority of Christianity over the old dispensation, inasmuch as Christ is superior (1) to the angels, (2) to Moses, (3) and chiefly to the Levitical priesthood and its mediatorship. In each of these relations, it is argued, the old covenant, which is earthly, temporal, and without finality, contains within itself the evidence of its own imperfection, and points to the time when it shall be superseded by a new covenant in which every reality and every hope is heavenly, eternal, or, as we should say, ideal. It is the form of this argument which mainly gives force to the common impression that the Hebrews addressed were in danger of seeking access to God by the superseded methods of the old dispensation—in short, that the epistle is a warning against an Ebionite tendency to Christian Pharisaism. But to such a tendency, as we have seen, the practical admonitions of the epistle by no means point. To some scholars accordingly, and particularly to Renss (*Histoire de la Théologie Chrétienne*, liv. vi. chap. 1; *Les Épîtres Catholiques*, Paris, 1878), the theoretical part of the book has seemed disproportionate to the practical and personal conclusion, and it has been proposed to regard the whole as a theological system with an epistolary appendix. Doubtless this view contains an element of truth. In a

¹ The statement of Renan, *L'Antechrist*, pp. xlv., 215, 219, that some had already fallen away and that the question of their readmission was being agitated, seems to be part of the ingenious historical romance in which he has enveloped the whole origin of the epistle.

far higher measure than the Pauline epistles, and in a sense which thoroughly well agrees with the position of the author as no apostle but an apostolic convert, the book presents the marks of theological reflexion on the established data of the faith. Yet it is impossible to ignore the fact that a special and practical motive runs through the whole book. The author never loses sight of a definite circle of readers, and the vast scope of his argument, which is at once felt in the dignity of the opening verses, so unlike the commencement of an ordinary letter, appears to be directly suggested by some historical circumstance affecting his readers and himself, but nowhere explicitly set forth in the epistle, which brought the trial of their faith into close connexion with the question of the permanence of the temple and its ritual. Now we have seen reason to believe that these Jewish Christians were not Palestinians of an Ebionite type but men of the Hellenistic dispersion, with a possible tendency to ascetic mysticism, and almost certainly of such a habit of thought as enabled them readily to sympathize with the typological method of our author. Among men of this type there was no great danger of a relapse into practical ceremonialism. They would rather be akin to the school of Judaism characterized by Philo (*De Migr. Abr.*, c. xvi.; ed. Mangey, i. 450), who neglected the observance of the ceremonial laws because they took them as symbols of ideal things. Occupying this position before their conversion, their adoption of the Christian faith would not have forced upon them any close examination of the relation of the new dispensation to the old law. But it appears from Philo that the men who spiritualized away the Sabbath, the great feasts, even circumcision itself, were not prepared to think lightly of the sacred ritual of the temple. The holy hill of God, the meeting-place of heaven and earth, with its stately service and its ancient memories, had too central a place in the religion of the old covenant to seem indifferent to the freest thinker. And so our Hebrews, whose acceptance of Christ had not shaken their sense of the continuity of the people of God and their Old Testament privileges, might readily retain the feeling that the ritual of the temple was still what it was of old—a visible and necessary pledge of God's approach to His people and His acceptance of their worship. So long as things ran their old course such a feeling would hardly affect the even tenor of their Christian life. But when the death struggle of Judea against Rome drew the sympathy of every Hebrew heart, when the abomination of desolation stood in the holy place, when the holy and beautiful house was burned up with fire, and when, with all this, terror and distress filled the whole Roman empire and still the Lord delayed His coming, it was not strange that something like despair of God's help should assail our Hebrews, and that all the hopes of the people of God should seem threatened in the overthrow of the ancient pledge of Jehovah's nearness to Israel.

Now it has generally been argued that the epistle to the Hebrews, which describes the temple services in the present tense, must necessarily have been written before they ceased to be performed. But it has been shown in the most conclusive manner, from the use of similar presents in Rabbinical writers as well as in Josephus and elsewhere, that this argument goes for nothing; and the most recent writers, since Holtzmann's discussion of the subject in Schenkel's *Bibel-Lexikon*, ii. 623 seq., generally admit that the epistle may have been written after the fall of the temple. And if this be so it can hardly be questioned that the most natural view of the apostle's argument, as it comes to a point in such passages as viii. 13, ix. 9, is that the disappearance of the obsolete ritual of the old covenant is no blow to Christian faith, because in Christ ascended into glory the church possesses in heavenly verity all that the

old ritual presented in mere earthly symbol. It was the ruin of the Jewish state and worship which compelled Christianity to find what is offered in our epistle—a theory, of the disappearance of the old dispensation in the new.

Many attempts have been made to determine which of the centres of the Diaspora was the seat of our Hebrews; Hofmann suggests Antioch; Ewald, Ravenna;¹ but Rome and Alexandria are the places for and against which most has been said. One argument for Alexandria on which great stress has been laid must certainly be dismissed. Wieseler (*Untersuchung über den Hebräerbrief*, ii^{te} Hälfte, Kiel, 1861), combining the arguments against a Palestinian address with the impression, which we have seen to be without sufficient foundation, that the readers lived in the neighbourhood of a Jewish temple, seeks them among the Egyptian Jews who frequented the schismatical temple of Leontopolis (Tel-el-Yahûdia) in the upper Delta. And he tries to show that in his description of the temple and the functions of the high priests our author diverges from the Judean pattern and follows peculiarities of the Egyptian temple. But this argument rests on a series of improbable assumptions. The supposed peculiarities of Onias's temple are proved by arbitrary exegesis from passages of Philo, who apparently never thought of that temple at all. Nor can it be shown that it had ever such a reputation as to play the part which Wieseler assigns to it. And our author's supposed ignorance of the Jerusalem ritual is not made out. In the true text of x. 11 the high priest is not mentioned, and in vii. 27 what is asserted of the high priest is, not that he offered daily sacrifice, but that he was in daily need of atonement. It is more difficult to understand why in ix. 4 the golden *θυμιατήριον*, that is, the censer or incense-altar,—for the usage of the word does not determine which is meant,—is assigned to the Holy of Holies. But a passage from the almost contemporary *Apocalypse of Baruch*, to which Harnack has directed attention (*Stud. u. Krit.*, 1876, p. 572 seq.), similarly connects the censer with the Holy of Holies, and seems to show that our author here proceeds on a current opinion and has not simply made a slip.² Apart from Wieseler's arguments, there is still something to be said for Alexandria. The use in ch. xi. of 2 Maccabees, an Egyptian Apocryphon,³ the general sympathy of the argument with Alexandrian thought, the apparent analogy between our Hebrews and the free-thinking Jews of whom Philo speaks, are all in favour of this address, though we do not know enough about the early history of the Egyptian Church to speak with positiveness either for or against this view of the epistle. Among Continental scholars the disposition at present is to favour the Roman address; upon which view, since that church was a mixed one, we must suppose that the letter was originally directed to a Jewish section of the Roman Christians. This is not quite plausible, especially since we find in the epistle no trace of the division of parties alluded to by Paul in his epistle from Rome to the Philippians. It is argued, however, that there is an analogy between the way of thinking of our Hebrews and the disposition of the majority of the Roman Church as it appears in Rom. ix. seq. The persecution x. 32 is supposed to be that of Nero, in which case *θεατριζόμενοι* may literally mean "exposed as a public spectacle"; and xiii. 7 is taken as an allusion to the martyrdom of Peter and Paul. In working

¹ *Das Sendschreiben an die Hebräer und Jakobus' Rundschreiben, übersetzt und erklärt von H. Ewald*, Gött., 1870.

² The Syriac word in Baruch is *Pirmâ*. To the passages cited by Harnack to establish for this word the sense of censer, not incense altar, may be added Bar Ali ed. Hoffmann, No. 2578; Barhebr., *Chron. Eccl.*, p. 507; Ezek. viii. 11 (Pesh. and Syr. Hex.).

³ Professor Plumpton, in the *Expositor*, vol. i., has also traced analogies with the book of Wisdom.

out this view there is great divergence of opinion; thus Renan will have it that the epistle was written from Ephesus in the year 65, while Harnack (*Patr. Ap.*, I. p. lxxxii.) thinks he finds traces of two distinct persecutions (i), and dates the book from the time of Domitian. The early currency of the epistle at Rome is urged in favour of the Roman address, but the ignorance of the Roman Church as to the author's name seems to go rather in the opposite direction. Ch. xiii. 24 gives us no help, for they of Italy (οἱ ἀπὸ τῆς Ἰταλίας) may in the epistolary style be Italians either at home or abroad. It is most natural to infer from x. 32 *seq.*, compared with xii. 4, that the church spoken of had not yet produced martyrs, but had suffered only by bonds and the loss of goods. This would exclude Rome, but perhaps the inference is not quite stringent.

Returning from this survey we bring little with us that can throw light on the authorship of the epistle. We can only say that the writer was a man of the first intellectual mark and of Alexandrian culture, whose home and work lay mainly among Jewish Christians, but who was at the same time associated with the Pauline circle. Of the names offered to us in other New Testament writings, Barnabas and Apollos seem the most likely, and Barnabas will claim the preference if we are entitled to give any weight to tradition. Either name would go well with the Alexandrian address. Apollos was an Alexandrian Jew. Barnabas was of Cyprus, always closely connected with Egypt; and the tradition which connects his relative and associate Mark with the Church of Alexandria is as old as the 2d century.

Literature.—A full account of the older literature will be found in Delitzsch's *Commentary*; and in the great work of Bleek (*Der Brief an die Hebräer erläutert durch Einleitung, Uebersetzung, und fortlaufenden Commentar*; Abth. I., *Versuch einer vollständigen Einleitung*, Berlin, 1828; Abth. II., *Uebersetzung und Commentar*, 1836, 1840), which has formed the basis for all subsequent work on the epistle, and is an indispensable storehouse of material for the student. Bleek's ultimate views on the exposition of the book may be gathered from the briefer posthumous work edited by Windrath (Eiberfeld, 1868). To the recent commentaries cited in the course of the article may be added those of Ebrard (1850; Eng. Trans., Edinburgh, 1853), Tholuck, (3d ed. 1850; Eng. Trans., Edinburgh, 1842), Lunemann (3d ed., Göttingen, 1867). For the doctrine of the epistle the most elaborate work is Riehm's very useful *Lehrbegriff des Hebräerbriefs*, Ludwigsburg, 1858-59; with which, in addition to the general works on New Testament theology by Weiss, Reuss, and others, the reader may compare Ritschl's *Entstehung der Altkatholischen Kirche*, 2d ed., p. 159 *seq.* (Bonn, 1857), and Pfeiderer's *Paulthomasus*, chap. ix. (Leipzig, 1873). An excellent summary of the present state of the critical questions bearing on the epistle is given by Zahn in the article "Hebräerbrief" in the new edition of Herzog's *Encyclopädie*. (W. R. S.)

HEBRIDES, THE, or WESTERN ISLES OF SCOTLAND, is a name sometimes applied collectively to all the islands on the west coast of Scotland, but seldom including Bute, Arran, and the other islands situated in the Firth of Clyde. The group is usually divided into the Outer Hebrides, or Long Island, and the Inner Hebrides. The former division embraces the Lewis, Harris, North and South Uist, Benbecula, Barra, and a number of small islands, the whole length of this group from Barra-Head to the Butt of Lewis being about 130 miles. The Inner Hebrides include Islay, Skye, Mull, Jura, Coll, Colonsay, Rum, Eigg, Tiree, Lismore, and Ulva. The number of inhabited islands is over 100, and the population is nearly 100,000. The principal islands are noticed under separate headings. The outer range consists almost exclusively of gneiss rocks, with poor soil and large proportions of peat and moor. The inner range is composed chiefly of trap and slate. The scenery of the islands may be generally described as partaking of the wild and sublime. Large masses of mountains of all forms tower up in the interior; and the coasts, indented by arms of the sea, are rugged and varied in outline. Spots of great beauty—green pastoral glens, sheltered

bays and lakes—are interspersed with the wildest scenes. The climate, though mild, is humid and unsuitable for corn crops. Only a very small portion of the surface is arable, the greater part being mountains, and the valleys intersecting them narrow and frequently covered with peat moss. Much of the land has, however, been converted into sheep walks, and the moors and desolate tracts are often let at high rents to sportsmen. The development of the prosperity of the islands has been greatly aided by the construction of excellent roads, and by the establishment of various lines of steamers in connexion with Glasgow, thus rendering the fine and in some respects unique scenery fully and easily accessible to tourists. One of the principal sources of wealth is that of the fisheries, Stornoway in the island of Lewis being the headquarters of that industry on the western coast.

The Hebrides are mentioned by Ptolemy under the name of Ἑβριδαί and by Pliny under that of *Hebrides*, the modern spelling having, it is said, originated in an accidental misprint. By the Norwegians they were called *Sudreyjar* or Southern Islands. The Latinized form was Sodorenses, preserved to modern times in the title of the bishop of Sodor and Man. The original inhabitants of the Hebrides seem to have been of the same Celtic race as those settled on the mainland—the Scoto-Irish whom Columba about the middle of the 6th century converted to Christianity. Scandinavian hordes then poured in with their northern idolatry and lust of plunder, but in time they adopted the language and faith of the islanders. Mention is made of incursions of the vikings on their shores as early as 793, but the principal emigration took place towards the end of the 9th century in the early part of the reign of Harold Haarfager, and consisted of persons driven thither, as well as to Orkney and Shetland, to escape from his tyrannous rule. Soon afterwards they began to make incursions against their mother-country, and on this account King Harold fitted out an expedition against them, and placed Orkney, Shetland, the Hebrides, and the Isle of Man under Norwegian government. The chief seat of the Norwegian sovereignty was Colonsay. About the year 1095 Godred Crovan, king of Dublin, of Man, and of the Hebrides, died in Islay. His third son, Olaus or Olave, succeeded to the government about 1103, and the daughter of Olaus was married to Somerled or Sorlet of Argyll, who became the founder of the dynasty known as Lords of the Isles. Many efforts were made by the Scottish monarchs to displace the Norwegians. Alexander II. led a fleet and army to the shores of Argyllshire in 1249, but he died in the island of Kerrera. On the other hand King Haco, at once to restrain the independence of his jarls and to keep in check the ambition of the Scottish kings, set sail in 1263 on a great expedition, which, however, ended disastrously. Magnus, son of Haco, concluded in 1266 a peace with the Scots, renouncing all claim to the Hebrides and other islands except Orkney and Shetland, and King Alexander agreed to give him a sum of 4000 merks in four yearly payments. It was also stipulated that Margaret, daughter of Alexander, should be betrothed to Eric, the son of Magnus, a connexion long remembered and lamented in Scottish song and story.

The race of Somerled continued to rule the islands, and from a younger son of the same potentate sprang the lords of Lorn, who took the patronymic of Macdonald. John Macdonald of Isle of Islay, who died about 1386, was the first to adopt the title of "Lord of the Isles." He was one of the most potent of the island princes, and was married to a daughter of the Earl of Strathern, steward of Scotland. His son, Donald of the Isles, was memorable for his rebellion in support of his claim to the earldom of Ross, in which, however, he was unsuccessful. Alexander, son of Donald, resumed the hereditary warfare against the Scottish crown; and in 1462 a treaty was concluded between Alexander's son and successor John and King Edward IV. of England, by which John, his son Donald Balloch, and his grandson John, became bound to assist King Edward and James, earl of Douglas, in subduing the kingdom of Scotland. The alliance seems to have led to no active operations, and the island king was adjudged to be a traitor to his liege sovereign of Scotland. In the reign of James V. another John of Islay resumed the title of "Lord of the Isles," but was compelled to surrender the dignity. The glory of the lordship of the isles—the insular sovereignty—had departed. From the time of Bruce the Campbells had been gaining the ascendancy in Argyll. The Macleans, Macnaughtons, Macclachlans, Lamonts, and other ancient races had sunk before this favourite family. The lordship of Lorn was wrested from the Macdonalds by Bruce, and their extensive possessions, with Dunstaffnage Castle, bestowed on the king's relative, Stewart, and his descendants, afterwards lords of Lorn. The Macdonalds of Sleat, the direct representatives of Somerled, though driven from Islay and deprived of supreme power by

James V., still kept a sort of insular state in Skye. There were also the Macdonalds of Clanranald and Glengary (descendants of Somerled), with the powerful houses of Macleod of Dunvegan and Macleod of Harris, McNeill of Barra and Maclean of Mull. Fierce sanguinary feuds continued throughout the 16th and 17th centuries among these rival clans and their dependent tribes, and the turbulent spirit was not subdued till a comparatively recent period. James VI. made an abortive endeavour to colonize Lewis. William III. and Queen Anne attempted to subsidize the chiefs in order to preserve tranquillity, but the wars of Montrose and Dundee, and the Jacobite insurrections of 1715 and 1745, showed how futile were all such efforts. It was not till 1748, when a decisive blow was struck at the power of the chiefs by the abolition of heritable jurisdictions, and the appointment of sheriffs in the different districts, that the arts of peace and social improvement made way in these remote regions.

The change was great, and at first not unmixed with evil. A new system of management and high rents were imposed, in consequence of which numbers of the tacksmen, or large tenants, emigrated to America. The exodus continued for many years. Sheep-farming on a large scale was next introduced, and the crofters were thrust into villages or barren corners of the land. The consequence was that, despite the numbers who entered the army or emigrated to Canada, the standard of civilization sank lower, and the population multiplied in the islands. The people came to subsist almost entirely on potatoes and herrings; and in 1846, when the potato blight commenced its ravages, a scene of nearly universal destitution ensued,—embracing, over the islands generally, 70 per cent. of the population. Temporary relief was administered in the shape of employment on roads and other works; and an emigration fund being raised, from 4000 to 5000 of the people in the most crowded districts were removed to Australia.

The principal books on the Hebrides are Martin's *Description of the Western Islands of Scotland*, 1703; Pennant's *Tour in Scotland and Voyage to the Hebrides*, 1774; Sir Joseph Bank's *Contributions to Pennant's Tour*; Boswell's *Tour to the Hebrides with Samuel Johnson*, LL.D.; Macculloch's *Geological Account of the Hebrides*, 1819; Hugh Miller's *Cruise of the Betsy*; W. A. Smith's *Lewisiana, or Life in the Outer Hebrides*, 1874. Their history under Norwegian rule is given in the *Chronica Regum Manniæ et Insularum*, edited, with learned notes, from the MS. in the British Museum by Professor P. A. Münch of Christiania, 1860.

HEBRON, the most southern of the three cities of refuge west of Jordan (Josh. xx. 7), built "seven years before Zoan (Tanis) in Egypt" (Num. xiii. 22). Tanis, according to Brugsch, was standing at least 2400 years B.C. Hebron was originally called Mamre and Kirjath Arba, after Arba, one of the Anakim (Josh. xiv. 15). It is frequently mentioned in the Old Testament (Gen. xiii. 18 and xxiii. 19; 2 Sam. iii. 20 and v. 5). The present town encloses the *Haram* or sanctuary built over the supposed site of Machpelah; but if this site be (as seems probable) genuine, the ancient Hebron must have faced the cave, as is remarked by many ancient writers (Gen. xxiii. 17). The name Machpelah signifies "place of division," and the cave was therefore called as early as the 6th century *Spelunca Duplex*. In the 12th century an iron door (still visible) is mentioned as leading from the Haram wall to the cavern. In 1167 A.D. Hebron became the see of a Latin bishop, and it was taken in 1187 by Saladin. In 1834 it joined the rebellion against Ibrahim Pasha, who took the town and pillaged it. Modern Hebron rises on the east slope of a shallow valley—a long narrow town of stone houses, the flat roofs having small stone domes. The main quarter is about 700 yards long, and two smaller groups of houses exist north and south of this. The hill behind is terraced, and luxuriant vineyards surround the place, which is well watered on the north by three principal springs, including the Well Sirah, now *'Ain Sarah* (2 Sam. iii. 26). Three conspicuous minarets rise, two from the Haram the other in the north quarter. The population includes 17,000 Moslems and 600 Jews. The Bedawin bring wool and camel's hair to the market; and glass bracelets, lamps, and leather water-skins are manufactured in the town. The modern name of Hebron is *Ei' Khalil*, "the friend," in allusion to Abraham the friend of God. The most conspicuous building is the *Haram*, an enclosure measuring

112 feet east and west by 198 north and south, surrounded with high rampart walls of masonry similar in size and dressing to that of the Jerusalem Haram walls. These ramparts are ascribed by architectural authorities to the Herodian period. The interior area is partly occupied by a 12th century Gothic church, and contains six modern cenotaphs of Abraham, Isaac, Jacob, Sarah, Rebecca, and Leah. The cave beneath the platform has probably not been entered for at least 600 years. The numerous traditional sites now shown round Hebron are traceable generally to mediæval legendary topography, including the tombs of Adam, Esau, Judah, Abner, and Jesse, the Field of Damascus, the Vale of Tears, and the Oak of Mamre ("plain" in A. V., Gen. xiii. 18), which has at various times been shown in different positions from $\frac{3}{4}$ mile to 2 miles from the town.

HECATÆUS, son of Hegesander, was sprung from an ancient and noble family of Miletus. His life seems to fall between the years 550 and 475 B.C. His earlier years were spent in travelling. He lived some time in Egypt (Herod., ii. 143); he was well acquainted with the resources and power of the Persian empire (Herod., v. 34); and the extant fragments of his writings seem to imply personal acquaintance with Libya, Spain, and Italy, as well as with the countries bordering on the Ægean and Euxine seas. After middle life he seems to have settled in Miletus, where he occupied a position of great honour, and to have devoted his time to the composition of geographical and historical works. When Aristagoras held a council of the leading Ionians at Miletus, to organize a revolt against the Persian rule, Hecatæus tried to dissuade his countrymen from the undertaking. Being overruled, he then advised them to equip a strong fleet, using for the emergency the treasures of the temple at Branchidæ, which might be repaid after the war. But both then and at a later period of the war (Herod., v. 124) his skilful and prudent advice was given in vain. When the remainder of the revolted Ionians sued for terms, he was one of the ambassadors sent to the Persian satrap Artabernes. He wrote a work on geography entitled *Περίπλους* or *Περιήγησις τῆς Γῆς*, in which he went over the countries of the known world, told their inhabitants, enumerated the towns, and described their situation and history. He improved the map of the world which Anaximander had made. He also wrote a work called *Γενεαλογία* or *Ἱστορίαι*, describing systematically the traditions and mythology of the Greeks. According to Arrian, he was the first to employ critical method to distinguish myth from historical fact; though he accepts Homer and the other poets as trustworthy authority. Herodotus, though obviously regarding him with respect, often controverts his statements.

HECATÆUS, of Abdera, sometimes confounded with Hecatæus of Miletus, was a Greek historian and philosopher of the 4th century B.C. He was a disciple of Pyrrho and a contemporary of Alexander the Great and Ptolemy Sotor. He accompanied the latter in an expedition to Syria, and during the reign of the same prince sailed up the Nile as far as Thebes. Some fragments of works by him on Egypt and on the Hyperboreans still exist. According to Suidas, he also wrote a treatise on the poetry of Hesiod and Homer. Regarding his authorship of a work on the Jews, of which some fragments remain, there is some disagreement among critics, but in all probability he is not the author of it.

The *Hecatæi Abderitæ Fragmenta* were collected by P. Zorn, and published at Altona in 1730. See C. Müller, *Histor. Græcor. frag.*, and Vossius, *De Historicis Græcis*.

HECATE, a Greek goddess who is never mentioned in Homer, but is of great importance in other parts of the literature as well as in religious observance. The name Hecatos, the masculine corresponding form, is a frequent

epithet of Apollo; and though the word *ἑκάτη* is never used exactly as an epithet of Artemis, yet this suggests a close relationship between the two goddesses, which an examination of their functions fully confirms. Their character and attributes stamp both as moon-goddesses. In fact, though often distinguished from Artemis, yet at other times Hecate is identified with her. The worship of Hecate seems to have flourished especially among the wilder tribes of Greek nationality, in Samothrace, Thessaly, and elsewhere; she has, however, been received into the Pantheon of the more civilized Greek races, probably on account of her close resemblance to Artemis; and this is doubtless the meaning of Hesiod's statement (*Theog.*, 423) that she alone of all the Titanic powers was left undisturbed in her honours by Zeus. The parentage of Hecate is variously given. Hesiod names her father Perseus (a word connected with Perseus, Persephone, &c., all of which denote powers of light) and her mother Asteria, the starry sky of night. Zeus and Demeter, Zeus and Hera, &c., are also named as her parents. Her chief prerogatives or functions are the following.

(1) She is the chief goddess who presides over magic arts and spells, for all incantations naturally were performed by the light of the moon. Medea is in this respect closely associated with her worship. See her prayer in Sophocles, *Rhizot. fr.* In Theocr., *Id. ii.*, where a woman's incantation to bring back her faithless lover is given, Hecate is constantly invoked. (2) She is a Chthonian power, and is worshipped at the Samothracian mysteries. She is then closely connected with Demeter. Alone of the gods besides Helios, she witnessed the abduction of Persephone, and torch in hand (a natural symbol for the moon's light), she assisted Demeter in the search for her daughter (*Hym. Dem.*, 45 ff.). She is obviously a by-form of Persephone, who as queen of the lower world is also the moon, the bride of the sun, when at setting he has gone to the lower world. She rules as a terrible power, Kratais, among the shades (*Orph.*, 48, &c.). (3) As *δαδούχος*, *φωσφόρος*, *ὑπολάμπτιρα*, she lights wanderers on their way by night, and is therefore, along with Hermes, worshipped as patron of roads under the name *ἑνοδία*. At cross-roads she was the director, hence her name *τριδιῆτις*, and probably also *τρίμορφος*, *τριπρόσωπος*, &c. Pillars called Hecatæa, like the *Hermæ*, stood, especially in Athens, at cross-roads and door-ways. (4) She is the goddess of fertility, and, like Artemis, presides especially over the birth and the youth of wild animals. As the moon measures the months, the moon-goddess in all forms, as Artemis, *Helsna*, &c., presides over birth. (5) It follows easily from the last that she should be the goddess who gives wealth and power. Thus she is celebrated by Hesiod (*l.c.*). On the Acropolis at Athens Hecate Epipyrgidia, as protectress of the citadel, had a shrine beside the temple of Victory. To Hecate dogs were offered, also honey and black she-lambs, as black victims were offered to other Chthonian deities. She was represented generally as a triple form, holding in the six hands torches, with sometimes a snake, a key, a whip, or a dagger, often with dogs standing beside her. The three heads support a basket, "kalathos," such as often adorns the statues of Artemis and Hera. The Hecatæa also generally represent her with three heads; occasionally, however, a single-formed Hecate is found, still with torch or key in hand, and sometimes with crescent moon on head.

HECKMONDWYKE, a town of England, in the West Riding of Yorkshire, on the Huddersfield and Bradford Railway, 2 miles N.W. of Dewsbury and 10 miles S.W. of Leeds. It occupies a gradually sloping site, and is somewhat irregularly built, although latterly it has assumed a more town-like appearance. It possesses a church

dedicated to St James erected in 1831, a market-house erected in 1868, a working men's club established in 1868, a mechanics' institute founded in 1873, a chamber of commerce dating from the same year, and a literary institute established in 1878. There are three board schools, a national school, and a Roman Catholic school, the whole affording accommodation for 1600 scholars. Much has been done for the improvement of the town by draining, and under the provisions of the Dewsbury and Heckmondwicke Waterworks Act of 1876 an ample supply of water has been obtained for domestic and manufacturing purposes. A cemetery with chapels for churchmen and dissenters was formed in 1860. The chief manufacture is blankets, and there are also carpet factories, machine shops, dye works, and iron foundries. Coal is extensively wrought in the vicinity. The town is under the government of a local board of health established in 1853. The area of the township is about 700 acres. The population of the town, which in 1801 was only 1742, had in 1871 reached 8300, and is now estimated at 10,000.

HECLA. See ICELAND.

HECTOR, son of Priam and Hecuba, the champion of the Trojans and the mainstay of their city. Like Paris and other Trojans, he had an Oriental name, Darius, as well as a Greek one, an interesting fact on which many fanciful theories have been founded. He was married to Andromache, daughter of Eetion, king in the Cilician Thebe. By Homer his character is drawn in most favourable colours as a good son, a loving husband and father, and a trusty friend,—religious without superstition, tenderhearted yet courageous. The one blemish apparent in some parts of the *Iliad* (see Geddes's *Homeric Problems*) is a tendency to presumptuous and boastful confidence. He is an especial favourite of Apollo; and later poets even describe him as son of that god. When Achilles, enraged with Agamemnon, deserted the Greeks, Hector drove them back to their ships, which he almost succeeded in burning. Patroclus, the friend of Achilles, who came to the help of the Greeks, was slain by Hector with the help of Apollo. Then Achilles, to revenge his friend's death, returned to the war, slew Hector, dragged his body behind his chariot to the camp, and afterwards dragged it round the tomb of Patroclus. Priam, guarded by Hermes, went to Achilles and prevailed on him to give back the dead body, which was buried with great honour (*Il.*, xxiv.). Hector was worshipped in the Troad by the Æolian tribe Gephyræi; and he is, like other heroes, probably an ancient god. It would require an inquiry into the whole Trojan legend to determine the conception involved: it is impossible to do more in this place than refer to Ruckert's essay in this direction.

Scenes from the life of Hector are favourite subjects in vase paintings. A very ancient pinax from Camirus represents his fight with Menelaus over the dead Euphorbus; and on an amphora, also from Camirus, of not later date than 450 B.C., he is represented starting for battle, standing beside the quadriga into which his charioteer Cebriones has already mounted. Both vases are now in the British Museum. Though many of the subjects in which he was supposed to appear have now been assigned to other heroes,—for example, the frequently occurring Parting of Hector and Andromache is by a more searching criticism generally transformed into a scene from the life of Amphiaraua,—yet many undoubted examples remain. We find such scenes as the parting cup given by Hecuba to her son as he departs to the battle, his battle with Achilles in presence of Apollo and Athene, or the dragging of his corpse round the tomb of Patroclus.

HECUBA (the Latin form of the Greek *Hekabe*), wife of Priam, is in Homer daughter of the Phrygian king Dymas, who dwelt on the bank of the Sangarius; but according to Euripides, Virgil, &c., her father was named Cisseus. According to Homer she was mother of nineteen of Priam's fifty sons. When Troy was captured and Priam

slain, she was made prisoner by the Greeks. Her fate is told in various ways, most of which connect her with the promontory Cynossema, on the Thracian shore of the Hellespont. According to Euripides (*Hekabe*), her youngest son Polydorus was placed during the siege under the care of Polymestor, king of Thrace. When the Greeks came to the Thracian Chersonese on their way home Hecuba discovered that her son Polydorus had been murdered, and in revenge she contrived to put out the eyes of Polymestor and murder his two sons. She was acquitted by Agamemnon; but, as Polymestor foretold, she was turned into a dog, and her grave became a mark for ships. Other tales about her may be found in Ovid (*Met.*, xiii. 423 ff.) and Dictys. It is obvious from the tales of Hecuba's transformation and death that she is a form of some goddess to whom dogs were sacred; and the analogy with Scylla is striking.

HEDA, WILLEM CLAASZ, Dutch painter, born at Haarlem it is said in 1594, and still living there in 1668, was one of the earliest Dutchmen who devoted himself exclusively to the painting of still life. He was the contemporary and comrade of Dirk Hals, with whom he had in common pictorial touch and technical execution. But Heda was more careful and finished than Hals, and showed considerable skill and not a little taste in arranging and colouring chased cups and beakers and tankards of precious and inferior metals. Nothing is so appetizing as his "luncheon," with rare comestibles set out upon rich plate, oysters,—seldom without the cut lemon,—bread, champagne, olives, and pastry. Even the commoner "refection" is also not without charm, as it comprises a cut ham, bread, walnuts, and beer. One of Heda's early masterpieces, dated 1623, in the Munich Pinakothek is as homely as a later one of 1651 in the Lichtenstein Gallery at Vienna. A more luxurious repast is a Luncheon in the Augsburg Gallery, dated 1644. Most of Heda's pictures are on the Continent, notably in the galleries of Paris, Parma, Ghent, Darmstadt, Gotha, Munich, and Vienna. He was a man of repute in his native city, and filled all the offices of dignity and trust in the guild of Haarlem. He seems to have had considerable influence in forming the younger Frans Hals.

HEDGEHOG (*Erinaceus europæus*, Linn.), the Common Urchin of Pennant, *Hérisson* of the French, *Riccio* of the Italians, *Igel* of the Germans, is the best known, and from an anatomical point of view perhaps the most characteristic, of the *Insectivora*. The genus is remarkable for its dentition, its armature of spines, and its short tail, while the ordinary species is characterized by not having the spines longer than the head or the ears more than half that length. The upper jaw is longer than the lower one, and the whole snout, which is long and flexible, has somewhat the appearance of that of the hog; the nostrils are narrow; and the claws are long but weak. The animal is about 10 inches long, its eyes are small, and the integument of the ventral surface is covered with hairs of the ordinary character. The brain is remarkable for its low degree of development, the cerebral hemispheres being excessively small, and marked with but one groove, and that a shallow one, on each side, while the more special characters of this region call to mind the organization of the same parts in the very lowest of mammals.

The most remarkable point in its external appearance is the possession of spines, and the power possessed by it of rolling itself up into a ball, from which these spines stand out in every direction. The spines, which are modified hairs, are sharp, hard, and elastic, and form so efficient a defence that there are but few animals that are able, and even they rarely, to effect a successful attack on this curious creature. The moment it is touched, or even hears the sound of so slight a menace as the report of a gun, it rolls

itself up by the action of the powerful muscles which lie just beneath the skin, while this same contraction effects the erection of the spines. The most important muscle is the *orbicularis panniculi*, which extends over the anterior region of the skull, as far down the body as the ventral or purely hairy region, and on to the tail; three other muscles are connected with this, and aid in the contraction of the integument, passing as they do from the breast-bone to the face and lower jaw, from the fore-arm to the sides of the ventral region, and from the fore-arm to the dorsal surface.

Though insectivorous, the hedgehog is reported to have a great liking for mice, while frogs and toads, as well as plants and fruits, all seem to be acceptable; its ingestion of snakes has been detailed by Buckland and Broderip, and its fondness for eggs has caused it to meet with the enmity of game-preservers. Pennant reports that "it lies under the undeserved reproach of sucking cattle, and hurting their udders, but the smallness of its mouth renders that impossible," nor does it seem that any well-authenticated report of such an occurrence has ever been made. It makes a not rare domestic pet. In a state of nature it does not emerge from its retreat during full daylight, unless urged out by hunger or by the necessities of its young. During the cold of winter it passes into a state of complete hibernation, and its temperature falls very considerably; having

Hedgehog.

provided itself with a nest of dry leaves, it is well protected from the influences of the rain, and rolling itself up it remains undisturbed till distinctly warmer weather returns. In July or August the female brings forth four to eight young, or, according to others (Bell), two to four at a somewhat earlier period; at birth the spines, which in the adult are black in the middle, are white and soft, but soon harden, though they do not attain their full size until the succeeding spring. It is commonly found in woods and gardens, and extends over nearly the whole of Europe; it has been found at 6000 to 8000 feet above the level of the sea. The witch in *Macbeth* who heard the "hedge-pig" whine thrice and once gave not an incorrect account of the character of its voice, rarely as this is heard. The adult is provided with thirty-six, and the young with twenty-four teeth; in both cases canines appear to be absent; the median incisors are very long, and project; there are two more false grinders in the upper than in the lower jaw, while the true molars of the upper jaw are remarkable for the presence of four cusps, of which the anterior inner and the posterior outer are connected by an obliquely-set ridge. This is the same arrangement as is seen in man. In the lower jaw the corresponding teeth are, as in the lemurs (or half apes), provided with two transverse ridges.

Sixteen species of the genus have been recognized by some zoologists. The tenrec (*Centetes*) of Madagascar has very many points in common with it.

HEDGE-SPARROW. See SPARROW.

HEEM, JAN DAVIDSZ VAN (or JOHANNES DE), was born according to Honbraken and Sandrart in 1604, according to Descamps in 1600, at Utrecht, and died at Antwerp in 1683 or 1684. Thoré has said of Heda, but it is only true of De Heem, that "he glorified insects, butterflies, and all the minute beings that swarm in vegetation, and made the moth drink in cups of chased gold." He was, if not the first, certainly the greatest painter of still life in Holland; no artist of his class combined more successfully perfect reality of form and colour with brilliancy and harmony of tints. No object of stone or silver, no flower humble or gorgeous, no fruit of Europe or the tropics, no twig or leaf, with which he was not familiar. Sometimes he merely represented a festoon or a nosegay. More frequently he worked with a purpose to point a moral or illustrate a motto. Here the snake lies coiled under the grass, there a skull rests on blooming plants. Gold and silver tankards or cups suggest the vanity of earthly possessions; salvation is allegorized in a chalice amidst blossoms, death as a crucifix inside a wreath. Sometimes De Heem painted alone, sometimes in company with men of his school, Madonnas or portraits surrounded by festoons of fruit or flowers. At one time he signed with initials, at others with Johannes, at others again with the name of his father joined to his own. At rare intervals he condescended to a date, and when he did the work was certainly of the best. De Heem entered the guild of Antwerp in 1635-6, and became a burgher of that city in 1637. He steadily maintained his residence till 1667, when he moved to Utrecht, where traces of his presence are preserved in records of 1668, 1669, and 1670. It is not known when he finally returned to Antwerp, but his death is recorded in the guild books of that place. A very early picture, dated 1628, in the gallery of Gotha, bearing the signature of Johannes in full, shows that De Heem at that time was familiar with the technical habits of execution peculiar to the youth of Albert Cuyp. In later years he completely shook off dependence, and appears in all the vigour of his own originality.

Out of 100 pictures or more to be met with in European galleries scarcely eighteen are dated. The earliest after that of Gotha is a chassé tankard, with a bottle, a silver cup, and a lemon on a marble table, dated 1640, in the museum of Amsterdam. A similar work of 1645, with the addition of fruit and flowers and a distant landscape, is in Lord Radnor's collection at Longford. A chalice in a wreath, with the radiant host amidst wheat sheaves, grapes, and flowers, is a masterpiece of 1648 in the Belvedere of Vienna. A wreath round a Madonna of life size, dated 1650, in the museum of Berlin, shows that De Heem could paint brightly and harmoniously on a large scale. In the Pinakothek at Munich is the celebrated composition of 1653, in which creepers, beautifully commingled with gourds and blackberries, twigs of orange, myrtle, and peach, are enlivened by butterflies, moths, and beetles. A landscape with a blooming rose tree, a jug of strawberries, a selection of fruit, and a marble bust of Pan, dated 1655, is in the Hermitage at St Petersburg; an allegory of abundance in a medallion wreathed with fruit and flowers, in the gallery of Brussels, is inscribed with De Heem's monogram, the date of 1663, and the name of an obscure artist called Lambrechts. All these pieces exhibit the master in full possession of his artistic faculties.

CORNELIUS DE HEEM, the son of Johannes, was in practice as a flower painter at Utrecht in 1658, and was still active in his profession in 1671 at the Hague. His pictures are not equal to those of his sire, but they are all well authenticated, and most of them in the galleries of the Hague, Dresden, Cassel, Vienna, and Berlin. In the Stadel at Frankfort is a fruit piece, with pot-herbs and a porcelain jug, dated 1658; another, dated 1671, is in the museum of Brussels. DAVID DE HEEM, another member of the family, entered the guild of Utrecht in 1668 and that of Antwerp in 1693. The best piece assigned to him is a table with a lobster, fruit, and glasses, in the gallery of Amsterdam; others bear his signature in the museums of Florence, St Petersburg, and Brunswick. It is well to guard against the fallacy that David de Heem above mentioned is the father of Jan de Heem. We should also be careful not to make two persons of the artist who sometimes signs Johannes, sometimes Jan Davidsz or J. D. Heem.

HEEMSKERK, JOHAN VAN (1597-1676), Dutch poet, was born at Amsterdam in 1597. He was educated as a child at Bayonne, and entered the university of Leyden in 1617. In 1621 he went abroad on the grand tour, leaving behind him his first volume of poems, *Minnckunst* (The Art of Love), which appeared in 1622. He was absent from Holland four years. He was made master of arts at Bourges in 1623, and in 1624 visited Hugo Grotius in Paris. On his return in 1625 he published *Minnckpligt* (The Duty of Love), and began to practise as an advocate in the Hague. In 1628 he was sent to England in his legal capacity by the Dutch East India Company, to settle the dispute respecting Amboyna. In the same year he published the poem entitled *Minnckkunde*, or the Science of Love. He proceeded to Amsterdam in 1640, where he married Alida, sister of the eminent statesman Van Beuningen. In 1642 he published *The Cid*, a tragic-comedy, and in 1647 his most famous work, the pastoral romance of *Batavische Arcadia*, which he had written ten years before. During the last twelve years of his life Heemskerk sat in the upper chamber of the states-general. His last poetical work was *The Inconstant Hygas*. He died at Amsterdam on the 27th of February 1656.

The poetry of Heemskirk, which fell into oblivion during the 18th century, is now once more read and valued. He takes a prominent place among writers of the second rank in the great age of Dutch literature. But his famous pastoral, the *Batavian Arcadia*, which was founded on the *Astrée* of Honoré d'Urfé, enjoyed a great popularity for more than a century, and passed through twelve editions. It provoked a host of more or less able imitations, of which the most distinguished were the *Doortische Arcadia* (1662) of Lambertus Bos, the *Zaanlandsche Arcadij* (1658) of Hendrik Zoeteboom, and the *Rotterdamsche Arcadia* (1703) of Willem den Elger. But the original work of Heemskerk, in which a party of nymphs and shepherds go out from the Hague to Katwijk, and there indulge in polite and pastoral discourse, surpasses all these in brightness and versatility.

HEEMSKERK, MARTIN JACOBZ (1498-1574), sometimes called Van Veen, was born at Heemskerk in Holland in 1498, and apprenticed by his father, a small farmer, to Cornelisz Willemsz, a painter at Haarlem. Recalled after a time to the paternal homestead and put to the plough or the milking of cows, young Heemskerk took the first opportunity that offered to run away, and demonstrated his wish to leave home for ever by walking in a single day the 50 miles which separate his native hamlet from the town of Delft. There he studied under a local master whom he soon deserted for John Schoreel of Haarlem. At Haarlem he formed what is known as his first manner, which is but a quaint and *gauche* imitation of the florid style brought from Italy by Mabuse and others. He then started on a wandering tour, during which he visited the whole of northern and central Italy, stopping at Rome, where he had letters for a cardinal. It is evidence of the facility with which he acquired the rapid execution of a scene-painter that he was selected to co-operate with Antonio da San Gallo, Battista Franco, and Francesco Salviati to decorate the triumphal arches erected at Rome in April 1536 in honour of Charles V. Vasari, who saw the battle-pieces which Heemskerk then produced, says they were well composed and boldly executed. On his return to the Netherlands he settled at Haarlem, where he soon (1540) became president of his guild, married twice, and secured a large and lucrative practice. In 1572 he left Haarlem for Amsterdam, to avoid the siege which the Spaniards laid to the place, and there he made a will which has been preserved, and shows that he had lived long enough and prosperously enough to make a fortune. At his death, which took place on the 1st of October 1574, he left money and land in trust to the orphanage of Haarlem, with interest to be paid yearly to any couple which should be willing to perform the marriage ceremony on the slab of

his tomb in the cathedral of Haarlem. It was a superstition which still exists in Catholic Holland that a marriage so celebrated would secure the peace of the dead within the tomb.

The works of Heemskerck are still very numerous, but by no means in the same demand as they were in the master's own time. Adam and Eve, and St Luke painting the Likeness of the Virgin and Child, in presence of a poet crowned with ivy leaves, and a parrot in a cage—an altar-piece in the gallery of Haarlem, and the *Ecce Homo* in the museum of Ghent, are characteristic works of the period preceding Heemskerck's visit to Italy. An altar-piece executed for St Laurence of Alkmaar in 1538-41, and composed of at least a dozen large panels, would, if preserved, have given us a clue to his style after his return from the south. In its absence we have a Crucifixion executed for the Riches Claires at Ghent (now in the Ghent Museum) in 1543, and the altar-piece of the Drapers' Company at Haarlem, now in the gallery of the Hague, and finished in 1546. In these we observe that Heemskerck studied and repeated the forms which he had seen at Rome in the works of Michelangelo and Raphael, and in Lombardy in the frescos of Mantegna and Giulio Romano. But he never forgot the while his Dutch origin or the models first presented to him by Schorel and Mabuse. As late as 1551 his memory still served him to produce a copy from Raphael's Madonna di Loreto (gallery of Haarlem). A Judgment of Momus, dated 1561, in the Berlin Museum, proves him to have been well acquainted with anatomy, but incapable of selection and insensible of grace, bold of hand and prone to daring though tawdry contrasts of colour, and fond of florid architecture. Two altar-pieces which he finished for churches at Delft in 1551 and 1559, one complete, the other a fragment, in the museum of Haarlem, a third of 1551 in the Brussels Museum, representing Golgotha, the Crucifixion, the Flight into Egypt, Christ on the Mount, and scenes from the lives of St Bernard and St Benedict, are all fairly representative of his style. Besides these we have the Crucifixion in the Hermitage of St Petersburg, and two Triumphs of Silenus in the gallery of Vienna, in which the same relation to Giulio Romano may be noted as we mark in the canvases of Rinaldo of Mantua. Other pieces of varying importance are in the galleries of Rotterdam, Munich, Cassel, Brunswick, Carlsruhe, Mainz, and Copenhagen. In England the master is best known by his drawings. A comparatively feeble picture by him is the Last Judgment in the palace of Hampton Court.

HEEREN, ARNOLD HERMANN LUDWIG (1760-1842), an eminent German historian, was born 25th October 1760 at Arbergen near Bremen. He studied philosophy, theology, and history at Göttingen, and thereafter travelled in Italy, France, and the Netherlands. In 1787 he was appointed one of the professors of philosophy at Göttingen, and he afterwards was chosen aulic councillor, privy councillor, &c., received in short those rewards which are the lot of successful German scholars. He died 7th March 1842. Heeren's great merit as an historian was that he regarded the states of antiquity from an altogether fresh point of view. He examined their economic relations, their constitutions, their financial systems, and thus was enabled to throw quite a new light on the development of the old world. He possessed vast and varied learning, perfect calmness and impartiality, and great power of historical insight. A French critic has thus briefly summed up his merits—"He had all the qualities of the historians of his nation without their defects, and there is not a French historian superior to him in clearness of thought and method of composition."

Heeren's chief works were—*Ideen über Politik, den Verkehr, und den Handel der vornehmsten Völker der alten Welt* (2 vols., Gött., 1793-1796; 4th ed., 5 vols., 1824-26; English trans., Oxford, 1833); *Geschichte des Studiums der classischen Literatur seit dem Wiederaufleben der Wissenschaften* (2 vols., Gött., 1797-1802; new ed., 1822); *Die Geschichte der Staaten des Alterthums* (Gött., 5th ed., 1826; English trans., Oxford, 1840); *Geschichte des europäischen Staatensystems* (Gött., 1800; 5th ed., 1830; English trans., 1834); *Versuch einer Entwicklung der Folgen der Kreuzzüge* (Gött., 1808, and, in French, Paris, 1808, a prize essay of the Institute of France). Besides these Heeren wrote brief biographical sketches of Joh. von Müller (Leipsic, 1810), Spittler (1812), and C. G. Heyne (Gött., 1813), founded with Ukert the famous historical collection *Geschichte der europ. Staaten* (Gotha, 1819, and following years), and contributed many papers to learned periodicals. A collection of Heeren's *Historische Werke* was published in 15 vols., 1821-26.

HEGEL, GEORG WILHELM FRIEDRICH (1770-1831), was born at Stuttgart on the 27th August 1770. His father, an official in the fiscal service of Würtemberg, is not otherwise known to fame; and of his mother, who died when her eldest son, the future philosopher, was in his fourteenth year, we only hear that she had scholarship enough to teach him the elements of Latin. He had one sister, Christiana, who died unmarried, and a brother Ludwig, who served in the campaigns of Napoleon.

At the gymnasium or grammar school of Stuttgart, where Hegel was educated between the ages of seven and eighteen, he was not remarkable. His main feat was a diary kept in German and to a less extent in Latin, at intervals during eighteen months (1785-7), to record and comment on incidents of the class-room, the street, and the parlour. His private industry was shown by written translations of the *Antigone*, the *Manual* of Epictetus, &c. But the characteristic feature of his studies was the copious extracts which from this time onward he unremittingly made and preserved. Alphabetically arranged under suitable heads, this strange congeries, forming his intimate library, comprised annotations on classical authors, passages from newspapers, whole treatises on morals and mathematics from the standard works of the period. It is the palpable exhibition of the marvellous receptivity by which he saturated himself with the thoughts of others, and absorbed in their integrity the raw materials for elaboration. Yet as evidence that he was not merely receptive we have essays already breathing that admiration of the classical world which he never lost. Even then too his chief amusement was cards, and even then he began the habit of taking snuff.

In the autumn of 1788 he entered at Tübingen as a student of theology; but though an exhibitor and on the foundation, if we may so call the "Stift," he showed no interest in the theology or philosophy of the place: his sermons were a failure; and, instead of seeking after academic distinction, he found more congenial reading in the classics, on the advantages of studying which his first essay was written. After two years he took the customary degree of Ph.D., and in the autumn of 1793 received his theological certificate, stating him to be of good abilities, but of middling industry and knowledge, and especially deficient in philosophy.

His university career, unlike that of Schelling, who, five years younger, came to Tübingen in 1790, was not brilliant. Hegel was quietly making himself at home in the Greek and Roman world, and gathering stores of miscellaneous information. Amongst his comrades he went by the title of "old man," such, it is said, being his withered aspect. He took part, however, in the usual walks and beer drinking, and even it seems love-making, of the student. But he gained most from intellectual intercourse with his contemporaries. Several of these are mentioned, but the two best known to fame were Hölderlin and Schelling. The former who was of the same age as Hegel, left for Jena about the time that Schelling arrived. With him Hegel learned to feel for the old Greeks a love which grew stronger as the semi-Kantianized theology of his teachers more and more failed to interest him. With Schelling like sympathies bound him. They both protested against the political and ecclesiastical inertia of their native state, and adopted with fervour the revolutionary doctrines of freedom and reason. The myth which tells how the two went out one morning to dance round a tree of liberty in a meadow is antedated, as the incident happened after they had left: still it is in keeping with their opinions, if unsuited to their character.

Like many a German student, Hegel was glad of a tutorship, in 1793, when his university course ended. For three years he taught the children of a M. Steiger of

Tschugg. Tschugg was the summer residence of the family, near Erlach on the lake of Biel; in winter they lived in Bern. Little happened in these years. Hegel had a few acquaintances in Bern; but, on the whole, intellectually he lived in isolation. He was, however, far from inactive. Local influences may explain a systematic account of the fiscal system of the canton Bern which he made for himself. But the main factor in Hegel's mental growth came from his study of Christianity. Under the impulse given by Lessing and Kant he turned to the original records of Christianity, and attempted to construe for himself the real significance of Christ. He wrote a life of Jesus, in which Jesus was simply the son of Joseph and Mary. He did not stop to criticize as a philologist, and simply ignored the miraculous. He asked for the secret contained in the conduct and sayings of this man which made him the hope of the human race. To Hegel Jesus appeared as revealing the unity with God in which the Greeks in their best days unwittingly rejoiced, and as lifting the eyes of the Jews from a lawgiver who metes out punishment on the transgressor, to the destiny which in the Greek conception falls on the just no less than on the unjust.

The interest of these lucubrations is in general twofold. In Jesus Hegel finds the expression for something higher than mere morality: he finds a noble spirit which rises above the contrasts of virtue and vice into the concrete life, seeing the infinite always embracing our finitude, and proclaiming the divine which is in man and cannot be overcome by error and evil, unless the man close his eyes and ears to the godlike presence within him. In religious life, in short, he finds the principle which reconciles the oppositions of the temporal and ordinary mind. But, secondly, the general source of the doctrine that life is higher than all its incidents and codes is of interest. He does not free himself from the current theology either by rational moralizing like Kant, or by bold speculative synthesis like Fichte and Schelling. He finds his panacea in the concrete life of humanity: he turns to history, and not to abstract speculation. But although he goes to the Scriptures, and tastes the mystical spirit of the mediæval saints, the Christ of his conception has traits that seem borrowed from Socrates and from the heroes of Attic tragedy, who suffer much and yet smile gently on a destiny to which they were reconciled. Instead of the Hebraic doctrine of a Jesus punished for our sins, we have the Hellenic idea of a man who is calmly tranquil in the consciousness of his unity with God.

During these years of arduous wrestling with the problems of religion, Hegel kept up a slack correspondence with Schelling and Hölderlin. Schelling was already on the way to fame. He was trying (to quote his own words) to find the premises to the results of Kant. Meanwhile he kept Hegel abreast with German speculation. Both of them were intent on forcing the theologians from their holes into the daylight, and grudged them any aid they might expect from Kant's postulation of God and immortality to crown the edifice of ethics. After lamenting his want of books, Hegel concludes a letter of 1795 with the words, "Let reason and freedom remain our watchword, and our point of union the church invisible." Great is their animus against the pietistic hypocrisy of Würtemberg. Meanwhile Hölderlin in Jena had been following Fichte's career with an enthusiasm with which he infected Hegel.

After these vehement struggles of thought, it is pleasing to turn to a short tour which Hegel in company with three other tutors made through the Bernese Oberland in July and August 1796. Of this tour he has left a minute diary. It embraced Lauterbrunnen, Grindelwald, the Grimsel, and the valley of the Reuss to the lake of Lucerne. The popular passion for natural scenery had scarcely begun, and the days of hotels and tourists were distant. Our four

tutors carried little luggage, save a pack of cards to while away the hours of rest. Hegel was particularly delighted with the varied play of the waterfalls. Still no glamour blinds him to the squalor of Swiss peasant life. The glaciers and the rocks call forth no raptures. "The spectacle of these eternally dead masses gave me nothing but the monotonous and at last tedious idea, 'Es ist so.'" Again, speaking of the upper parts of the Hasli-thal: "I doubt if the most orthodox theologian would be held enough in these regions to credit nature with the purpose of being useful to man, who with difficulty must wrest from her the scanty pittance of which he can make use,—who is uncertain whether rocks or avalanches may not crush him to pieces even as he steals a poor handful of grass, and destroy his miserable hut and cow-stall, the wretched work of his hands."

Towards the close of his engagement at Bern, Hegel had received hopes from Schelling of a post at Jena. Tired of isolation, he was anxious to get away from Bern. Fortunately his friend Hölderlin, who was now tutor in Frankfurt, secured a similar situation there for Hegel in the family of a Herr Gogol, a merchant. Hegel entered upon his new post in January 1797. It was apparently more agreeable, and left more time for study. At the same time he was nearer the centre of public interest. But above all it renewed the much-missed intellectual society. Hölderlin was still, as formerly, enamoured of the ideal of ancient Greece. And another friend called Sinclair, a Fichtean, the author of several forgotten philosophical works, helped to animate Hegel's interest in philosophy.

It may have been the political position of Frankfurt that made Hegel about this time turn to questions of economics and government. He had studied Gibbon, Hume, and Montesquieu in Switzerland. We now find him making copious extracts from the English newspapers on the Poor-Law Bill of 1796; criticizing the Prussian land laws, promulgated about the same time; and writing a commentary on Sir James Steuart's *Inquiry into the Principles of Political Economy*, as a means of defining his own views on economics. Here, as in contemporaneous criticisms of Kant's ethical writings, Hegel aims at correcting the abstract discussion of a topic by treating it in its systematic interconnexions. Church and state, law and morality, commerce and art, are reduced to factors in the totality of human life, from which the specialists had isolated them.

But the best evidence of Hegel's attention to contemporary politics is two unpublished essays—one of them written in 1798, "On the Internal Condition of Würtemberg in Recent Times, particularly on the Defects in the Magistracy," the other a criticism on the constitution of Germany, written, it is probable, not long after the peace of Lunéville (1801). Both essays show more vigour in pointing out the inadequacies of the present than in suggesting a remedy. Criticism, not construction, is their forte. In the first Hegel showed how the supineness of the committee of estates in Würtemberg had favoured the usurpations of the superior officials in whom the court had found compliant servants. And though he perceived the advantages of change in the constitution of the estates, he still doubted if an improved system could work in the actual conditions of his native province. The main feature in the pamphlet is the recognition that a spirit of reform is abroad. If Würtemberg suffered from a bureaucracy tempered by despotism, the Fatherland in general suffered no less. "Germany," so begins the second of these unpublished papers, "is no longer a state." Referring the collapse of the empire to the retention of feudal forms and to the action of religious animosities, Hegel looked forward to reorganization by a central power (Austria) wielding the imperial army, and by a representative body elected by the geographical dia-

tricts of the empire. But such an issue, he saw well, could only be the outcome of violence—of “blood and iron.” The philosopher did not pose as a practical statesman. He only described the German empire in its nullity as a conception without existence in fact. In such a state of things it was the business of the philosopher to set forth the outlines of the coming epoch, as they were already moulding themselves into shape, amidst what the ordinary eye saw only as the disintegration of the old forms of social life.

His old interest in the religious question reappears, but in a more philosophical form. Starting with the contrast between a natural and a positive religion, he regards a positive religion as one imposed upon the mind from without, not a natural growth crowning the round of human life. A natural religion, on the other hand, was not, he thought, the one universal religion of every clime and age, but rather the spontaneous development of the national conscience varying in varying circumstances. A people's religion completes and consecrates their whole activity: in it the people rises above its finite life in limited spheres to an infinite life where it feels itself all at one. Even philosophy with Hegel at this epoch was subordinate to religion; for philosophy must never abandon the fruit in the search for the infinite. Soon, however, Hegel adopted a view according to which philosophy is a higher mode of apprehending the infinite than even religion.

At Frankfort, meanwhile, the philosophic ideas of Hegel first assumed the proper philosophic form. “In my scientific training,” he says (in a letter to Schelling of November 2, 1800), “which started from more subordinate wants of man, I could not but be forced onwards to science, and at the same time the ideal of youth had to transform itself into the reflective form of a system.” In a MS. of 102 quarto sheets, of which the three first and the seventh are wanting, there is preserved the original sketch of the Hegelian system, so far at least as the logic and metaphysics and part of the philosophy of nature are concerned. The third part of the system—the ethical theory—seems to have been composed afterwards; it is contained in its first draught in another MS. of thirty sheets. Even these had been preceded by earlier Pythagorean constructions envisaging the divine life in divine triangles.

Circumstances soon put Hegel in the way to complete these outlines. His father died in January 1799; and the slender sum which Hegel received as his inheritance, 3154 gulden (about £260), enabled him to think once more of a studious life. At the close of 1800 we find him asking Schelling for letters of introduction to Bamberg, where with cheap living and good beer he hoped to prepare himself for the intellectual excitement of Jena. The upshot was that Hegel arrived at Jena in January 1801. An end had already come to the brilliant epoch at Jena, when the romantic poets, Tieck, Novalis, and the Schlegels made it the headquarters of their fantastic mysticism, and Fichte turned the results of Kant into the banner of revolutionary ideas. Schelling was the main philosophical lion of the time; and in some quarters Hegel was spoken of as a new champion summoned from Swabia by Schelling to help him in his struggle with the more prosaic continuators of Kant. Hegel's first performance seemed to justify the rumour. It was an essay on the difference between the philosophic systems of Fichte and Schelling, tending in the main to support the latter. Still more striking was the agreement shown in the *Critical Journal of Philosophy*, which Schelling and Hegel wrote conjointly during the years 1802–3. So latent was the difference between them at this epoch that it, in one or two cases, is not with certainty possible to determine by whom the essay was written. Even at a later period foreign critics like Cousin saw much that was alike in the two doctrines, and did not

hesitate to regard Hegel as a disciple of Schelling. The dissertation by which Hegel qualified for the position of privat-docent—an essay, *De orbitis planetarum*—was probably chosen under the influence of Schelling's philosophy of nature. It was an unfortunate subject. For while Hegel, depending on a numerical proportion suggested by Plato, hinted in a single sentence that it might be a mistake to look for a planet in the interval between Mars and Jupiter, Professor Piazzi had already discovered the first of the asteroids on 1st January 1801. Apparently in August, when Hegel qualified, the news of the discovery had not yet reached him, but critics have made this luckless suggestion the ground of attack on *a priori* philosophy. The theses attached to this dissertation contained some characteristic paradoxes, *e.g.*, that the syllogism is the principle of idealism, that a square is the law of nature, and a triangle of mind, &c.

Hegel's earliest lectures, in the winter of 1801–2, on logic and metaphysics were attended by about eleven students. At a later period, in 1804, we find him with a class of about thirty, lecturing on his whole system; but his average attendance was rather less. Besides philosophy, he once at least lectured on mathematics. As he taught, he was led to modify his original system, and notice after notice of his lectures promised a text-book of philosophy—which, however, failed to appear. Meanwhile, after the departure of Schelling from Jena in the middle of 1803, Hegel was left to work out his own views. Besides philosophical studies, where he now added Aristotle to Plato, he read Homer and the Greek tragedians, made extracts from books, attended lectures on physiology, and dabbled in other sciences. On his own representation at Weimar, he was in February 1805 made a professor extraordinarius, and in July 1806 drew his first and only stipend—100 ralers. At Jena, though some of his hearers became devotedly attached to him, Hegel was not a popular lecturer any more than Krause. The ordinary student found Fries more intelligible.

Of the lectures of that period there still remain considerable notes. The language often had a theological tinge (never entirely absent), as when the “idea” was spoken of, or “the night of the divine mystery,” or the dialectic of the absolute called the “course of the divine life.” Still his view was growing clearer, and his difference from Schelling more palpable. Both Schelling and Hegel stand in a relation to art, but while the æsthetic model of Schelling was found in the contemporary world, where art was a special sphere and the artist a separate profession in no intimate connexion with the age and nation, the model of Hegel was found rather in those works of national art in which art is not a part of the common life but an aspect of it, and the artist is not a mere individual but a concentration of the passion and power of beauty in the whole community. “Such art,” says Hegel, “is the common good and the work of all. Each generation hands it on beautified to the next; each has done something to give utterance to the universal thought. Those who are said to have genius have acquired some special aptitude by which they render the general shapes of the nation their own work, one in one point, another in another. What they produce is not their invention, but the invention of the whole nation; or rather, what they find is that the whole nation has found its true nature. Each, as it were, piles up his stone. So too does the artist. Somehow he has the good fortune to come last, and when he places his stone the arch stands self-supported.” Hegel, as we have already seen, was fully aware of the change that was coming over the world. “A new epoch,” he says, “has arisen. It seems as if the world-spirit had now succeeded in freeing itself from all foreign objective existence, and finally apprehending itself as absolute mind.”

These words come from lectures on the history of philosophy, which laid the foundation for his "Phenomenology of the Mind." The printing of this work (*Phänomenologie des Geistes*) began in 1806 at Bamberg, and the sheets were distributed, as they appeared, to a class where he treated the phenomenology as an introduction to logic. That course he closed on the 18th September 1806, as follows:—"This, gentlemen, is speculative philosophy, so far as I have worked it out. We stand in a momentous time,—a seething mass, in which the mind has made a sudden bound, left its old shape behind, and is gaining a new. The whole bulk of our old ideas, the very bands of the world, are rent asunder, and collapse like a dream. Mind is preparing a new start. Philosophy, above all things, has to own and welcome such a start. While some in powerless resistance cling to the past, and the majority help, but unconsciously, to swell the numbers of its cortege, philosophy, recognizing it as the eternal, has to show it due honour."

Less than a month after, on the 14th October 1806, Napoleon was at Jena. But Hegel, like Goethe, felt no patriotic shudder at the victory, and in Prussia he saw only a corrupt and conceited bureaucracy. Writing to his friend Niethammer on the day before the battle, he speaks only with admiration of the "world-soul," the emperor, and only with satisfaction of the probable overthrow of the badly-generall and inefficient Prussians. The scholar's wish was to see the clouds of war pass away, and leave thinkers to their peaceful work. His manuscripts were his main care; and doubtful of the safety of his last despatch to Bamberg, and disturbed by the French soldiers in his lodgings, he hurried off, with the last pages of the *Phenomenology* in his pocket, to take refuge in the pro-rector's house. Hegel's fortunes were now at the lowest ebb. Without means, and obliged to borrow from his friend Niethammer, he had no further hopes from the impoverished university. He had already tried to get away from Jena. In 1805, when several lecturers left in consequence of diminished classes, he had written to Voss suggesting that his philosophy might find more congenial soil in Heidelberg; but the application bore no fruit. Now, however, it was necessary to do something. And so, when the proprietor of the *Bamberger Zeitung* was in want of an editor, Hegel, who had been named by Niethammer, at once accepted the offer, which involved a certain partnership in the concern. Early in 1807 he came to Bamberg, and stayed for about eighteen months. Of his editorial work there is little to tell; no leading articles appeared in his columns. Patriotic indignation against Napoleon, or interest in the fortunes of Prussia, were not wanted, and probably would not have been allowed. The editor was only expected to give his constituency news, and he did so with proper neutrality and from the best sources available. It was not a lofty or suitable vocation; and when a nomination to the rectorship of the Aegidien-gymnasium in Nuremberg was procured for Hegel, again by the agency of Niethammer, who was now in the education office at Munich, he was glad to go.

From December 1808 to August 1816 Hegel was school-master. Bavaria, at this time under the direction of Montgelas, was modernizing her institutions. The school system was reorganized by new regulations, which, *inter alia*, prescribed a training in philosophy as part of the gymnasial course. To this regulation (with which Hegel, however, was not agreed) we owe a series of lessons in the outlines of philosophy—ethical, logical, and psychological—which Hegel drew up with great care and many revisions. They were published in 1840 by Rosenkranz from Hegel's papers. Deviating somewhat from the official order, he began with the outlines of moral and religious doctrine; he then proceeded to psychology and a combined system of

logic and metaphysics, and ended with a general summary of the whole of philosophy.

As a teacher and master Hegel seems to have been fairly successful. He inspired confidence in his pupils, and maintained discipline without pedantic interference in their associations and sports. On the prize-days at the close of the session, his addresses summing up the history of the school year discussed some topic of general interest. Five of these addresses are preserved. The first is an exposition of the advantages of a classical training, when it is not confined to mere points of grammar. "The perfection and grandeur of the master-works of Greek and Roman literature must be the intellectual bath, the secular baptism, which gives the first and unfading tone and tincture of taste and science." The school was mainly classical; yet at least one half of the time was given to arithmetic, history and geography, mathematics, physics, and preliminary philosophy. In another address, speaking of the introduction of military exercises at school, he says:—"These exercises, while not intended to withdraw the students from their more immediate duty, so far as they have any calling to it, still remind them of the possibility that every one, whatever rank in society he may belong to, may one day have to defend his country and his king, or help to that end. This duty, which is natural to all, was formerly recognized by every citizen, though whole ranks in the state have become strangers to the very idea of it."

On the 16th September 1811, in the summer vacation, Hegel married Marie von Tucher. The young lady (twenty-two years younger than her bridegroom) belonged to Nuremberg, and seems to have been all that could be wished for in a wife. She brought her husband no fortune, but a cheerful heart. They seem to have had a happy if a frugal home; and a short excursion now and then was their chief dissipation. The husband kept a careful record of income and expenditure. That income at Nuremberg amounted to 1500 gulden (£130) and a house; at Heidelberg, as professor, he received about the same sum; but at Berlin his regular stipend was about 3000 thalers (£300). Two sons were born to them; the eldest, Karl, born 7th June 1813, has since become eminent as a historian. The younger was named Immanuel, born on the 24th September 1816. Hegel's letters to his wife, written during his solitary holiday tours to Vienna, the Netherlands, and Paris, breathe of kindly and happy affection. Hegel, the tourist, recalling happy days spent together; confessing that, were it not because of his sense of duty as a traveller, he would rather be at home, dividing his time between his books and his wife; commenting on the shop windows at Vienna; describing the straw hats of the Parisian ladies,—is a contrast to the professor of a profound philosophical system. But it shows that the enthusiasm which in his days of courtship moved him to verse had blossomed into a later age of domestic bliss.

The year after his marriage appeared the first two volumes of his *Wissenschaft der Logik*, and the work was completed by a third in 1816. This work, in which his system was for the first time presented in what, if we except a few minor alterations, was its ultimate shape, found some audience in the world, and from here and there came voices of encouragement. Sinclair, who in 1811 brought out three volumes on *Truth and Certainty*; Windischmann, subsequently professor at Bonn; Thaden, a Danish peasant farmer and votary of free thought; Berger, another Dane and philosopher; Van Ghert, an old pupil, now a Government official at Amsterdam,—these, as well as Knebel and Niethammer, corresponded with him during this period. Towards the close of his eighth session three professorships were almost simultaneously put within his reach,—at Erlangen, Berlin, and Heidelberg. The Prussian

offer expressed a doubt that his long absence from university teaching might have made him rusty, so he accepted the post at Heidelberg, whence Fries had just gone to Jena. He came to Heidelberg in October 1816. Though charmed with the neighbourhood, and pleased with the people, he was a little disappointed when only four hearers turned up for one of his courses. Others, however, on the encyclopædia of philosophy and the history of philosophy drew classes of twenty to thirty. While he was there, Cousin first made his acquaintance, but a more intimate relation dates from Berlin. Among his pupils was Hinrichs, who, originally a law student, became a philosophical disciple and wrote several works, to one of which, *Religion in its Inward Relation to Science*, Hegel wrote a rather important preface in 1822. The strangest of his hearers was an Esthonian baron, Boris d'Yrkull, who after serving in the Russian army came to Heidelberg to hear the wisdom of Hegel. But his books and his lectures were alike obscure to the baron, who betook himself by Hegel's advice to some simpler fare, in the shape of rudimentary knowledge, before he returned to the Hegelian system. The logic of his master, with whom he became intimate, was afterwards his constant companion in his travels.

At Heidelberg Hegel was also active in a literary way. In 1817 he brought out the *Encyclopædia of the Philosophical Sciences*, in outline, for use at his lectures. In its first form it was a small treatise of about 300 octavo pages; but in the second of 1827, and the third of 1830, it rapidly grew to twice the original bulk. It is the only exposition of the Hegelian system as a whole which we have direct from Hegel's own hand. Besides this work he wrote two reviews for the Heidelberg *Jahrbücher*—the first on Jacobi, the other a political pamphlet which called forth violent criticism. It was entitled a *Criticism on the Transactions of the Estates of Würtemberg in 1815-16*. On the 15th March 1815 King Frederick of Würtemberg, at a meeting of the estates of his kingdom, laid before them the draft of a new constitution, in accordance with the resolutions of the congress of Vienna. Though an improvement on the old constitution, it was unacceptable to the estates, jealous of their old privileges and suspicious of the king's intentions. A decided majority demanded the restitution of their old laws, though the kingdom now included a large population to which the old rights were strange. Hegel in his essay, which was republished at Stuttgart, strongly supported the royal proposals, and severely animadverted on the backwardness of the bureaucracy and the landed interests. In the main he was right; but he forgot too much the provocation they had received, the usurpations and selfishness of the governing family, and the unpatriotic character of the king.

After two years at Heidelberg Hegel accepted the renewed offer of the chair of philosophy at Berlin, which had been kept vacant since the death of Fichte. The hopes which this offer raised of a position less precarious than that of a university teacher of philosophy were in one sense disappointed; for more than a professor Hegel never became. But his influence upon his pupils, and his solidarity with the Prussian Government, gave him a position such as few professors have held.

On the 22d October 1818 Hegel began his lectures at Berlin. "Our business and vocation," he said to his young hearers, "is to cherish the philosophical development of the substantial foundation (*i.e.*, the state) which has renewed its youth and increased its strength." But Prussia had already proved false to the spirit of freedom which had armed the peoples against Napoleon. The enthusiasm which in the hands of Stein, Humboldt, and Scharnhorst had reformed the social, intellectual, and military organization of Prussia still smouldered; but hot-headed youth-

ful politicians made it burst into fitful flames. Sober men were disgusted by the absurdities perpetrated at the Wartburg to celebrate the tricentenary of the Reformation. And though professors like Fries and Oken shared the behaviour of the students in this demonstration, and the assassination of Kotzebue in 1819 found admirers—such as the theological professor De Wette, who spoke of it as a "beautiful sign of the time"—Stein spoke of the two professors as a pair of fools, and Niebuhr grew sad over the extravagances of the younger generation. Secret societies were formed or believed to be forming; and the Governments grew alarmed. In Prussia the reaction triumphed by the withdrawal of Humboldt in the last days of 1819; and the death of Hardenberg in 1822 was followed by a period of bureaucracy and conservatism.

It was in such an atmosphere that Hegel published the "Philosophy of Right" (*Grundlinien der Philosophie des Rechts*) in 1821. It is a combined system of moral and political philosophy, or a sociology dominated by the idea of the state. It turns away contemptuously and fiercely from the sentimental aspirations of reformers possessed by the democratic doctrine of the rights of the omnipotent nation. Fries is stigmatized as one of the "ringleaders of shallowness" who were bent on substituting a fancied tie of enthusiasm and friendship for the established order of the state. The disciplined philosopher, who had devoted himself to the task of comprehending the organism of the state, had no patience with feebler or more mercurial minds who recklessly laid hands on established ordinances, and set them aside where they contravened humanitarian sentiments. With the principle that whatever is real is rational, and whatever is rational is real, Hegel fancied that he had stopped the mouths of political critics and constitution-mongers. His theory was not a mere formulation of the Prussian state. Much that he construed as necessary to a state was wanting in Prussia; and some of the reforms already introduced did not find their place in his system. Yet, on the whole, he had taken his side with the Government. Altenstein even expressed his satisfaction with the book. In his disgust at the crude conceptions of the enthusiasts, who had hoped that the war of liberation might end in a realm of internal liberty, Hegel had forgotten his own youthful vows recorded in verse to Hölderlin, "never, never to live in peace with the ordinance which regulates feeling and opinion." And yet if we look deeper we see that this is no worship of existing powers. It is rather due to an overpowering sense of the value of organization,—a sense that liberty can never be dis severed from order, that a vital interconnexion between all the parts of the body politic is the source of all good, so that while he can find nothing but brute weight in an organized public, he can compare the royal person in his ideal form of constitutional monarchy to the dot upon the letter *i*. A keen sense of how much is at stake in any alteration breeds suspicion of every reform.

During his thirteen years at Berlin Hegel's whole soul seems to have been in his lectures. Between 1823 and 1827 his activity reached its maximum. His notes were subjected to perpetual revisions and additions. We can form an idea of them from the shape in which they appear in his published writings. These on *Æsthetics*, on the *Philosophy of Religion*, on the *Philosophy of History*, and on the *History of Philosophy*, have been published by his editors, mainly from the notes of his students, under their separate heads; while those on logic, psychology, and the philosophy of nature are appended in the form of illustrative and explanatory notes to the sections of his *Encyclopædie*. During these years hundreds of hearers from all parts of Germany, and from beyond the Fatherland, came under his influence. His fame was carried abroad by eager

or intelligent disciples. At Berlin Henning served to prepare the intending disciple for fuller initiation by the master himself. Gans and Hotho carried the method into special spheres of inquiry. At Halle Hinrichs maintained the standard of Hegelianism amid the opposition or indifference of his colleagues.

Hegel himself in his class-room was neither imposing nor fascinating. You saw a plain, old-fashioned face, without life or lustre—a figure which had never looked young, and was now bent and prematurely aged; the furrowed face bore witness to concentrated thought. Sitting with his snuff-box before him, and his head bent down, he looked ill at ease, and while still speaking kept turning the folios of his notes. His utterance was interrupted by frequent hemming and coughing; every word and every sentence came out with a struggle; and if, when the right word seemed as if it would never come and no progress appeared to be making, the listener for a moment ceased to listen, he found when attention returned that the lecture had reached a new stage, and the connexion was lost. And the style of these utterances was no less irregular. Sometimes in the plainest narrative the lecturer would be specially awkward, while in the abstrusest passages he seemed specially at home, rose into a natural eloquence, and carried away the hearer by the grandeur of his diction.

Three courses of lectures are especially the product of his Berlin period: those on æsthetics, the philosophy of religion, and the philosophy of history. In the years preceding the revolution of 1830, public interest, excluded from political life, turned to theatres, concert-rooms, and picture galleries. At these Hegel became a frequent and appreciative visitor. He even made extracts from the art-notes in the newspapers. In his holiday excursions, the interest in the fine arts is prominent, and more than once takes him out of his way to see some old painting. His letters to his wife are full of such topics. A visit to Vienna in 1824 presents him spending every moment at the Italian opera, the ballet, and the picture galleries. In Paris, in 1827, curiously enough, he heard Charles Kemble and an English company play Shakespeare. This familiarity with the actual facts of art, though neither very deep nor very historical, gave an unusual freshness to his lectures on æsthetics, which, as put together from the notes of 1820, 1823, 1826, are in many ways the most successful of his efforts.

The lectures on the philosophy of religion are another application of his method to an important sphere of human interest. Shortly before his death he had prepared for the press a course of lectures on the proofs for the existence of God. In his lectures on religion he dealt with Christianity, as in his philosophy of morals he had regarded the state. On one hand he turned his weapons against the rationalistic school, who reduced religion to the modicum compatible with an ordinary worldly mind. On the other hand he criticized the school of Schleiermacher, who elevated feeling to a place in religion above systematic theology. His middle way attempts to show that the dogmatic creed is the rational development of what was implicit in religious feeling. To do so, of course, philosophy becomes the interpreter and the superior. To the new school of Hengstenberg, which regarded Revelation itself as supreme, such interpretation was an abomination.

A Hegelian school began to gather. The flock included intelligent pupils who applied the method in different provinces of speculation, empty-headed imitators who repeated the catchwords of the new dialectic, and romantic natures who turned philosophy into lyric measures. Opposition and criticism, which were not wanting, only served to define more precisely the adherents of the new doctrine. The master himself grew more and more into a belief in his own doctrine as the one truth for the world. The system

had grown gradually with him, and had assimilated intellectual nutriment from every hand so as to make all history and all knowledge bear witness to its truth. He was in harmony with the Government, and his followers were on the winning side. Though he had soon resigned all direct official connexion with the schools of Brandenburg, his real influence in Prussia was considerable, and as usual was largely exaggerated in popular estimate. In the narrower circle of his friends his birthdays were the signal for congratulatory verses. In 1826 a formal festival was got up by some of his admirers, one of whom, Herder, spoke of his categories as new gods; and he was presented with much poetry and a silver mug. In 1830 the students struck a medal in his honour, and in 1831 he was decorated by an order from the king. In 1830 he was rector of the university; and on the tricentenary of the Augsburg Confession in that year, he took the opportunity in his speech on the occasion to charge the Catholic Church with regarding the virtues of the pagan world as brilliant vices, and giving the crown of perfection to poverty, continence, and obedience.

One of the last literary undertakings in which he took part was to give his support to Gans and Varnhagen von Ense in the establishment of the Berlin *Jahrbücher für Wissenschaftliche Kritik*. The aim of this review was to give a critical account, certified by the names of the contributors, of the more important literary and philosophical productions of the time, in relation to the general progress of knowledge. The journal was not solely in the Hegelian interest; and more than once, when Hegel attempted to domineer over the other editors, he was met by vehement and vigorous opposition. It gave him besides a deal of trouble with sanguine authors, who looked forward to a favourable word from him as a passport to fame.

The revolution of 1830 was a great blow to him, as to many other Germans; and the prospect of democratic advances almost made him ill. His last literary work was an essay on the English Reform Bill of 1831, the first part of which appeared in the *Preussische Staatszeitung*. It contains primarily a careful consideration of the effects likely to come from the alterations in the electoral franchise, in relation, first, to the character of the new members of parliament, and secondly, to the measures which they may introduce. In the latter connexion he enlarges on several points where England had done less than many Continental states for the abolition of monopolies and abuses. Surveying with much intelligence of English circumstances the questions connected with landed property, with the game laws, the poor, the Established Church, especially in Ireland, Hegel throws grave doubt on the legislative capacity of the English parliament as compared with the power of renovation and reform manifested in the more advanced states of western Europe. Much of the essay, unfortunately, has not become antiquated as a critique on the social state of Britain.

In 1831 the cholera had first entered Europe. Hegel and his family retired for the summer to a lodging in the suburbs, and there he finished the revision of the first part of his *Science of Logic*. On the commencement of the winter session, however, he returned to his house in the Kupfergraben. On this occasion an unseemly altercation occurred between him and his friend Gans, who in his notice of lectures on jurisprudence had recommended Hegel's *Philosophy of Right*. Hegel, indignant at what he deemed patronage, asked Gans in a rough missive to withdraw the note. On Friday 11th November Hegel had lectured as usual. On Sunday he had a violent attack of cholera, and on Monday, the 14th November 1831, he was dead. He was buried on the spot he had wished for himself, between Fichte and Solger.

Hegel's Philosophy.

Hegelianism is confessedly one of the most difficult of all philosophies. Every one has heard the legend which makes Hegel say, "One man has understood me, and even he has not." He abruptly hurls us into a world where old habits of thought fail us. In three places indeed he has attempted to exhibit the transition to his own system from other levels of thought; but in none with much success. In the introductory lectures on the philosophy of religion he gives a rationale of the difference between the modes of consciousness in religion and philosophy (between *Vorstellung* and *Begriff*). In the beginning of the *Encyclopædie* he discusses the defects of dogmatism, empiricism, the philosophies of Kant and Jacobi. In the first case he treats the formal or psychological aspect of the difference; in the latter he presents his doctrine less in its essential character than in special relations to the prominent systems of his time. The *Phenomenology of Spirit*, regarded as an introduction, suffers from a different fault. It is not an introduction—for the philosophy which it was to introduce was not then fully elaborated. Even to the last Hegel had not so externalized his system as to treat it as something to be led up to by gradual steps. His philosophy was not one aspect of his intellectual life, to be contemplated from others; it was the ripe fruit of concentrated reflection, and had become the one all-embracing form and principle of his thinking. More than most thinkers he had quietly laid himself open to the influences of his time, and the lessons of history.

The *Phenomenology* is the picture of the Hegelian philosophy in the making,—at the stage before the scaffolding has been removed from the building. For this reason the book is at once the most brilliant and the most difficult of Hegel's works,—the most brilliant because it is to some degree an autobiography of Hegel's mind,—not the abstract record of a logical evolution, but the real history of an intellectual growth; the most difficult because, instead of treating the rise of intelligence (from its first appearance in contrast with the real world to its final recognition of its presence in, and rule over, all things) as a purely subjective process, it exhibits this rise as wrought out in historical epochs, national characteristics, forms of culture and faith, and philosophical systems. The theme is identical with the introduction to the *Encyclopædie*; but it is treated in a very different style. From all periods of the world,—from mediæval piety and stoical pride, Kant and Sophocles, science and art, religion and philosophy,—with disdain of mere chronology, Hegel gathers in the vineyards of the human spirit the grapes from which he crushes the wine of thought. The human mind coming through a thousand phases of mistake and disappointment to a sense and realization of its true position in the universe,—such is the drama which is consciously Hegel's own history, but is represented objectively in the field of the world as the process of spiritual history which the philosopher wakes into consciousness and reproduces in himself. The *Phenomenology* stands to the *Encyclopædie* somewhat as the dialogues of Plato stand to the Aristotelian treatises. It contains almost all his philosophy—but irregularly and without due proportion. The personal element gives an undue prominence to recent and contemporary phenomena of the philosophic atmosphere. It is the account given by an inventor of his own discovery, not the explanation of an outsider. It therefore to some extent assumes from the first the position which it proposes ultimately to reach, and gives, not a proof of that position, but an account of the experience (*Erfahrung*) by which consciousness is forced from one position to another till it finds rest in *Absolutes Wissen*.

It is impossible in a mere resumé to do justice to this remarkable work, which is neither a mere psychology, nor logic, nor moral philosophy, nor history, but is all of these at once and a great deal more. What the *Phenomenology* wants is not distillation, but expansion and illustration from contemporary and antecedent thought and literature. It treats of the attitudes of consciousness towards reality under the six heads of consciousness, self-consciousness, reason (*Vernunft*), spirit (*Geist*), religion, and absolute knowledge. The native attitude of consciousness towards existence is reliance on the evidence of the senses; but a little reflexion is sufficient to show that the reality attributed to the external world is as much due to intellectual conceptions as to the senses, and that these conceptions slip through our fingers when we try to fix them. If consciousness cannot detect a permanent object outside it, so self-consciousness cannot find a permanent subject in itself. It may, like the Stoic, assert freedom by holding aloof from the entanglements of real life, or like the sceptic regard the world as a delusion, or finally, as the "unhappy consciousness" (*Unglückliches Bewusstseyn*), may be a recurrent falling short of a perfection which it has placed above it in the heavens. But in this isolation from the world, self-consciousness has closed its gates against the stream of life. The perception of this is reason. Reason convinced that the world and the soul are alike rational observes the external world, mental phenomena, and specially the nervous organism, as the meeting ground of body and mind. But reason finds much in the world recognizing no kindred with her, and so turning to practical activity seeks in the world the realization of her own aims. Either in a crude way she

pursues her own pleasure, and finds that necessity counteracts her cravings; or she endeavours to find the world in harmony with the heart, and yet is unwilling to see fine aspirations crystallized by the act of realizing them. Finally, unable to impose upon the world either selfish or humanitarian ends, she folds her arms in pharisaic virtue, with the hope that some hidden power will give the victory to righteousness. But the world goes on in its life, heedless of the demands of virtue. The principle of nature is to live and let live. Reason abandons her efforts to mould the world, and is content to let the aims of individuals work out their results independently, only stepping in to lay down precepts for the cases where individual actions conflict, and to test these precepts by the rules of formal logic.

So far we have seen consciousness on one hand and the real world on the other. The stage of "Geist" reveals the consciousness no longer as critical and antagonistic but as the indwelling spirit of a community, as no longer isolated from its surroundings but the union of the single and real consciousness with the vital feeling that animates the community. This is the lowest stage of concrete consciousness—life, and not knowledge; the spirit inspires, but does not reflect. It is the age of unconscious morality, when the individual's life is lost in the society of which he is an organic member. But increasing culture presents new ideals, and the mind, absorbing the ethical spirit of its environment, gradually emancipates itself from conventions and superstitions. This "Aufklärung" prepares the way for the rule of conscience, for the moral view of the world as subject of a moral law. From the moral world the next step is religion; the moral law gives place to God; but the idea of God-head, too, as it first appears is imperfect, and has to pass through the forms of nature-worship and of art, before it reaches a full utterance in Christianity. Religion in this shape is the nearest step to the stage of absolute knowledge; and this absolute knowledge—"the spirit knowing itself as spirit"—is not something which leaves these other forms behind but the full comprehension of them as the organic constituents of its empire; "they are the memory and the sepulchre of its history, and at the same time the actuality, truth, and certainty of its throne." Here, according to Hegel, is the field of philosophy.

The preface to the *Phenomenology* signalled the separation from Schelling—the adieu to romantic. It declared that a genuine philosophy has no kindred with the mere aspirations of artistic minds, but must earn its bread by the sweat of its brow. It sets its face against the idealism which either thundered against the world for its deficiencies, or sought something finer than reality. Philosophy is to be the science of the actual world—it is the spirit comprehending itself in its own externalizations and manifestations. The philosophy of Hegel is idealism, but it is an idealism in which every idealistic unification has its other face in the multiplicity of existence. It is realism as well as idealism, and in its highest speculations never quits its hold on facts. Compared with Fichte and Schelling, Hegel has a sober, hard, realistic character. At a later date, with the call of Schelling to Berlin in 1841, it became fashionable to speak of Hegelianism as a negative philosophy requiring to be complemented by a "positive" philosophy which would give reality and not mere ideas. The cry was the same as that of Krug (more than once alluded to by Hegel) asking the philosophers who expounded the absolute to construe his pen. It was the cry of the Evangelical school for a personal Christ and not a dialectical Logos. Philosophy, as Schelling says, was asked to supply the real God and not the mere conception of Him. Experimental science complained that the real world of matter and force had been supplanted by a fantastic tissue of logical forms and ethereal processes. The claims of the individual, the real, material, and historical fact had been sacrificed, it was said, by Hegel, to the universal, the ideal, the spiritual, and the logical.

There was a truth in these criticisms. It was the very aim of Hegelianism to render fluid the fixed phases of reality,—to show existence not to be an immovable rock limiting the efforts of thought, but to have thought implicit in it, waiting for release from its petrification. Nature was no longer, as with Fichte, to be a mere spring-board to evoke the latent powers of the spirit. Nor was it, as in Schelling's earlier system, to be a collateral progeny with mind from the same womb of indifference and identity. Nature and mind in the Hegelian system—the external and the spiritual world—have the same origin, but are not co-equal branches. The natural world proceeds from the "idea," the spiritual from the idea and nature. It is impossible, beginning with the natural world, to explain the mind by any process of distillation or development, unless consciousness or its potentiality has been there from the first. Reality, independent of the individual consciousness, there must be; reality, independent of all mind, is an impossibility. At the basis of all reality, whether material or mental, there is thought. But the thought thus regarded as the basis of all existence is not consciousness with its distinction of ego and non-ego. It is rather the stuff of which both mind and nature are made, neither extended as in the natural world, nor self-centred as in mind. Thought in its primary form is, as it were, thoroughly transparent and absolutely

fluid, free, and mutually interpenetrable in every part,—the spirit in its seraphic scientific life, before creation had produced a natural world, and thought had risen to independent existence in the social organism. Thought in this primary form, when in all its parts completed, is what Hegel calls the "idea." But the idea, though fundamental, is in another sense final, in the process of the world. It only appears in consciousness as the crowning development of the mind. Only with philosophy does thought become fully conscious of itself in its origin and development. Accordingly the history of philosophy is the presupposition of logic, or the three branches of philosophy form a circle.

The exposition or constitution of the "idea" is the work of the Logic. As the total system falls into three parts, so every part of the system follows the triadic law. Every truth, every reality, has three aspects or stages; it is the unification of two contradictory elements, of two partial aspects of truth which are not merely contrary, like black and white, but contradictory, like same and different. The first step is a preliminary affirmation and unification, the second a negation and differentiation, the third a final synthesis. For example, the seed of the plant is an initial unity of life, which when placed in its proper soil suffers disintegration into its constituents, and yet in virtue of its vital unity keeps these divergent elements together, and reappears as the plant with its members in organic union. Or again, the process of scientific induction is a threefold chain; the original hypothesis (the first unification of the fact) seems to melt away when confronted with opposite facts, and yet no scientific progress is possible unless the stimulus of the original unification is strong enough to clasp the discordant facts and establish a reunification. Thesis, antithesis, and synthesis, a Fichtean formula, is generalized by Hegel into the perpetual law of thought.

In what we may call their psychological aspect these three stages are known as the abstract stage, or that of understanding (*Verstand*), the dialectical stage, or that of negative reason, and the speculative stage, or that of positive reason (*Ideanität*). The first of these attitudes taken alone is dogmatism; the second, when similarly isolated, is scepticism; the third, when unexplained by its elements, is mysticism. Thus Hegelianism reduces dogmatism, scepticism, and mysticism to factors in philosophy. The abstract or dogmatic thinker believes his object to be one, simple, and stationary, and intelligible apart from its surrounding. He speaks, e.g., as if species and genera were fixed and unchangeable; and fixing his eye on the ideal forms in their purity and self-sameness, he scorns the phenomenal world, whence this identity and persistence are absent. The dialectic of negative reason rudely dispels these theories. Appealing to reality it shows that the identity and permanence of forms are contradicted by history; instead of unity it exhibits multiplicity, instead of identity difference, instead of a whole, only parts. Dialectic is, therefore, a dislocating power; it shakes the solid structures of material thought, and exhibits the instability latent in such conceptions of the world. It is the spirit of progress and change, the enemy of convention and conservatism; it is absolute and universal unrest. In the realm of abstract thought these transitions take place lightly. In the worlds of nature and mind they are more palpable and violent. So far as this Hegel seems on the side of revolution. But reason is not negative or dialectic only; it binds up as well as breaks down, and, while it disintegrates the mass or unconscious unity, builds up a new unity with higher organization. But this third stage is the place of effort, requiring neither the surrender of the original unity nor the ignoring of the diversity afterwards suggested. The stimulus of contradiction is no doubt a strong one; but the easiest way of escaping it is to shut our eyes to one side of the antithesis. What is required, therefore, is to readjust or reconstitute our original thesis in such a way as to include and give expression to both the elements in the process.

The universe, then, is a process or development, to the eye of philosophy. It is the process of the absolute—in religious language, the manifestation of God. In the background of all the absolute is eternally present; the rhythmic movement of thought is the self-unfolding of the absolute. God reveals Himself in the logical idea, in nature, and in mind; but mind is not alike conscious of its absoluteness in every stage of development. Philosophy alone sees God revealing Himself in the ideal organism of thought as it were a possible deity prior to the world and to any relation between God and actuality; in the natural world, as a series of materialized forces and forms of life; and in the spiritual world as the human soul, the legal and moral order of society, and the creations of art, religion, and philosophy.

This introduction of the absolute became a stumbling-block to Feuerbach and other members of the "Left." They rejected as an illegitimate interpolation the eternal subject of development, and, instead of one continuing God as the subject of all the predicates by which in the logic the absolute is defined, assumed only a series of ideas, products of philosophic activity. They denied the theological value of the logical forms,—the development of these forms being in their opinion due to the human thinker, not to a self-revealing absolute. Thus they made man the creator of the absolute. But

with this modification on the system another necessarily followed; a mere logical series could not create nature. And thus the material universe became the real starting-point. Thought became only the result of organic conditions—subjective and human; and the system of Hegel was no longer an idealization of religion, but a naturalistic theory with a prominent and peculiar logic.

The logic of Hegel is the only rival to the logic of Aristotle. What Aristotle did for the theory of demonstrative reasoning, Hegel attempted to do for the whole of human knowledge. His logic is an enumeration of the forms or categories by which our experience exists. It carried out Kant's doctrine of the categories as *a priori* synthetic principles, but removed the limitation by which Kant denied them any constitutive value except in alliance with experience. According to Hegel the terms in which thought exhibits itself are a system of their own, with laws and relations which reappear in a less obvious shape in the theories of nature and mind. Nor are they restricted to the small number which Kant obtained by manipulating the current subdivision of judgments. But all forms by which thought holds sensations in unity (the formative or synthetic elements of language) had their place assigned in a system where one leads up to and passes over into another.

The fact which ordinary thought ignores, and of which ordinary logic therefore provides no account, is the presence of gradation and continuity in the world. The general terms of language simplify the universe by reducing its variety of individuals to a few forms, none of which exist simply and perfectly. The method of the understanding is to divide and then to give a separate reality to what it has thus distinguished. It is part of Hegel's plan to remedy this one-sided character of thought, by laying bare the gradations of ideas. He lays special stress on the point that abstract ideas when held in their abstraction are almost interchangeable with their opposites—that extremes meet, and that in every true and concrete idea there is a coincidence of opposites.

The beginning of the logic is an illustration of this. The simplest term of thought is being; we cannot think less about anything than when we merely say that it is. Being—the abstract "is"—is *nothing* definite, and nothing at least is. Being and not being are thus declared identical,—a proposition which in this unqualified shape was to most people a stumbling-block at the very door of the system. Instead of the mere "is" which is as yet nothing, we should rather say "becomes," and as "becomes" always implies "something," we have determinate being—"a being" which in the next stage of definiteness becomes "one."—And in this way we pass on to the quantitative aspects of being.

It is impossible to give a brief account of the long development of thought, especially as the cogency of the demonstration lies in the details. The logical idea is treated under the three heads of being (*Sein*), essence (*Wesen*), and notion (*Begriff*). The terms treated under the first head, in addition to those already mentioned, are the abstract principles of quantity and number, and their application in measure to determine the limits of being. Under the title of essence are discussed those pairs of correlative terms which are habitually employed in the explanation of the world,—such as law and phenomenon, cause and effect, reason and consequence, substance and attribute. Under the head of notion are considered, firstly, the subjective forms of conception, judgment, and syllogism; secondly, their realization in objects as mechanically, chemically, or teleologically constituted; and thirdly, the idea first of life, and next of science, as the complete interpenetration of thought and objectivity. The third part of logic evidently is what contains the topics usually treated in logic-books, though even here the province of logic in the ordinary sense is exceeded. The first two divisions—the "objective logic"—are what is usually called metaphysics.

The characteristic of the system, and one impossible to exhibit in a resumé, is the gradual way in which idea is linked to idea so as to make the division into chapters only an arrangement of convenience. The judgment is completed in the syllogism; the syllogistic form as the perfection of subjective thought passes into objectivity, where it first appears embodied in a mechanical system; and the teleological object, in which the members are as means and end, leads up to the idea of life, where the end is means and means end indissolubly till death. In some cases these transitions may be unsatisfactory and forced; it is apparent that the linear development from "being" to the "idea" is got by transforming into a logical order the sequence that has roughly prevailed in philosophy from the Eleatics; cases might be quoted where the reasoning seems a play upon words; and it may often be doubted whether certain ideas do not involve extra-logical considerations. The order of the categories is in the main outlines fixed; but in the minor details much depends upon the philosopher, who has to fill in the gaps between ideas, with little guidance from the data of experience, and to assign to the stages of development names which occasionally deal hardly with language. The merit of Hegel is to have indicated and to a large extent displayed the filiation and mutual limitation of our forms of thought; to have arranged them in the order of their comparative capacity to give a satisfactory expression to truth

in the totality of its relations; and to have broken down the partition which in Kant separated the formal logic from the transcendental analytic, as well as the general disruption between logic and metaphysic. It must at the same time be admitted that much of the work of weaving the terms of thought, the categories, into a system has a hypothetical and tentative character, and that Hegel has rather pointed out the path which logic must follow, viz., a criticism of the terms of scientific and ordinary thought in their filiation and interdependence, than himself in every case kept to the right way. The day for a fuller investigation of this problem will partly depend upon the progress of the study of language in the direction marked out by W. von Humboldt.

The Philosophy of Nature starts with the result of the logical development, with the full scientific "idea." But the relations of pure thought, losing their inwardness, appear as relations of space and time; the abstract development of thought appears as matter and movement. Instead of thought, we have perception; instead of dialectic, gravitation; instead of causation, sequence in time. The whole falls under the three heads of mechanics, physics, and "organic,"—the content under each varying somewhat in the three editions of the *Encyclopædie*. The first treats of space, time, matter, movement; and in the solar system we have the representation of the idea in its general and abstract material form. Under the head of physics we have the theory of the elements, of sound, heat, and cohesion, and finally of chemical affinity,—presenting the phenomena of material change and interchange in a series of special forces which generate the variety of the life of nature. Lastly, under the head of "organic," come geology, botany, and animal physiology,—presenting the concrete results of these processes in the three kingdoms of nature.

The charges of superficial analogies, so freely urged against the "Natur-philosophie" by critics who forget the impulse it gave to physical research by the identification of forces then believed to be radically distinct, do not particularly affect Hegel. But in general it may be said that he looked down upon the mere natural world. The meanest of the fancies of the mind and the most casual of its whims he regarded as a better warrant for the being of God than any single object of nature. Those who supposed astronomy to inspire religious awe were horrified to hear the stars compared to eruptive spots on the face of the sky. Even in the animal world, the highest stage of nature, he saw a failure to reach an independent and rational system of organization; and its feelings under the continuous violence and menaces of the environment he described as insecure, anxious, and unhappy.

His point of view was essentially opposed to the current views of science. To metamorphosis he only allowed a logical value, as explaining the natural classification; the only real, existent metamorphosis he saw in the development of the individual from its embryonic stage. Still more distinctly did he contravene the general tendency of scientific explanation. "It is held the triumph of science to recognize in the general process of the earth the same categories as are exhibited in the processes of isolated bodies. This is, however, an application of categories from a field where the conditions are finite to a sphere in which the circumstances are infinite." In astronomy he depreciates the merits of Newton and elevates Kepler, accusing Newton particularly, *à propos* of the distinction of centrifugal and centripetal forces, of leading to a confusion between what is mathematically to be distinguished and what is physically separate. The principles which explain the fall of an apple will not do for the planets. As to colour, he follows Goethe, and uses strong language against Newton's theory, for the barbarism of the conception that light is a compound, the incorrectness of his observations, &c. In chemistry, again, he objects to the way in which all the chemical elements are treated as on the same level.

The third part of the system is the Philosophy of Mind. Its three divisions are the "subjective mind" (psychology), the "objective mind" (philosophic jurisprudence, moral and political philosophy), and the "absolute mind" (the philosophy of art, religion, and philosophy). The subjects of the second and third divisions have been treated by Hegel with great detail. The "objective mind" is the topic of the *Rechts-Philosophie*, and of the lectures on the Philosophy of History; while on the "absolute mind" we have the lectures on *Æsthetic*, on the Philosophy of Religion, and on the History of Philosophy—in short, more than one-third of his works.

The purely psychological branch of the subject takes up half of the space allotted to "Geist" in the *Encyclopædie*. It falls under the three heads of anthropology, phenomenology, and psychology proper. Anthropology treats of the mind in union with the body;—of the natural soul,—and discusses the relations of the soul with the planets, the races of mankind, the differences of age, dreams, animal magnetism, insanity, and phrenology. In this obscure region it is rich in suggestions and rapprochements; but the ingenuity of these speculations attracts curiosity more than it satisfies scientific inquiry. In the *Phenomenology* consciousness, self-consciousness, and reason are dealt with. The title of the section and the contents recall, though with some important variations, the earlier half of his

first work; only that here the historical background on which the stages in the development of the ego were represented has disappeared. Psychology, in the stricter sense, deals with the various forms of theoretical and practical intellect such as attention, memory, desire, and will. In this account of the development of an independent, active, and intelligent being from the stage where man like the Dryad is a portion of the natural life around him, Hegel has combined what may be termed a physiology and pathology of the mind,—a subject far wider than that of ordinary psychologies, and one of vast intrinsic importance. It is, of course, easy to set aside these questions as unanswerable, and to find artificiality in the arrangement. Still it remains a great point to have even attempted some system in the dark anomalies which lie under the normal consciousness, and to have traced the genesis of the intellectual faculties from animal sensibility.

The theory of the mind as objectified in the institutions of law, the family, and the state is discussed in the "Philosophy of Right." Beginning with the antithesis of a legal system and morality, Hegel, carrying out the work of Kant, presents the synthesis of these elements in the ethical life (*Sittlichkeit*) of the family and the state. Treating the family as an instinctive realization of the moral life, and not as the result of contract, he shows how by the means of wider associations due to private interests the state issues as the full home of the moral spirit, where intimacy of interdependence is combined with freedom of independent growth. The state is the consummation of man as finite; it is the necessary starting-point whence the spirit rises to an absolute existence in the spheres of art, religion, and philosophy. In the finite world or temporal state, religion, as the finite organization of a church, is, like other societies, subordinate to the state. But on another side, as absolute spirit, religion, like art and philosophy, is not subject to the state, but belongs to a higher region.

The political state is always an individual, and the relations of these states with each other and the "world-spirit" of which they are the manifestations constitute the material of history. The *Lectures on the Philosophy of History*, edited by Gans and subsequently by Karl Hegel, is the most popular of Hegel's works. The history of the world is a scene of judgment where one people and one alone holds for awhile the sceptre, as the unconscious instrument of the universal spirit, till another rises in its place, with a fuller measure of liberty—a larger superiority to the bonds of natural and artificial circumstance. Three main periods—the Oriental, the Classical, and the Germanic—in which respectively the single despot, the dominant order, and the man as man possess freedom—constitute the history of the world. Inaccuracy in detail and artifice in the arrangement of isolated peoples are inevitable in such a scheme. A graver mistake, according to some critics, is that Hegel, far from giving a law of progress, seems to suggest that the history of the world is nearing an end, and has merely reduced the past to a logical formula. The answer to this charge is partly that such a law seems unattainable, and partly that the idealistic content of the present which philosophy extracts is always an advance upon actual fact, and so does throw a light into the future. And at any rate the method is greater than Hegel's employment of it.

But as with Aristotle so with Hegel—beyond the ethical and political sphere rises the world of absolute spirit in art, religion, and philosophy. The psychological distinction between the three forms is that sensuous perception (*Anschauung*) is the organon of the first, presentative conception (*Vorstellung*) of the second, and free thought of the third. The work of art, the first embodiment of absolute mind, shows a sensuous conformity between the idea and the reality in which it is expressed. The so-called beauty of nature is for Hegel an adventitious beauty. The beauty of art is a beauty born in the spirit of the artist and born again in the spectator; it is not like the beauty of natural things, an incident of their existence, but is "essentially a question, an address to a responding breast, a call to the heart and spirit." The perfection of art depends on the degree of intimacy in which idea and form appear worked into each other. From the different proportion between the idea and the shape in which it is realized arise three different forms of art. When the idea, itself indefinite, gets no further than a struggle and endeavour for its appropriate expression, we have the symbolic, which is the Oriental, form of art, which seeks to compensate its imperfect expression by colossal and enigmatic structures. In the second or classical form of art the idea of humanity finds an adequate sensuous representation. But this form disappears with the decease of Greek national life, and on its collapse follows the romantic, the third form of art; where the harmony of form and content again grows defective, because the object of Christian art—the infinite spirit—is a theme too high for art. Corresponding to this division is the classification of the single arts. First come architecture—in the main, symbolic art; then sculpture, the classical art *par excellence*; they are found, however, in all three forms. Painting and music are the specially romantic arts. Lastly, as a union of painting and music comes poetry, where the sensuous element is more than ever subordinate to the spirit.

The lectures on the Philosophy of Art stray largely into the next sphere and dwell with zest on the close connexion of art and religion; and the discussion of the decadence and rise of religions, of the æsthetic qualities of Christian legend, of the age of chivalry, &c., make the *Æsthetik* a book of varied interest.

The lectures on the Philosophy of Religion, though unequal in their composition and belonging to different dates, serve to exhibit the vital connexion of the system with Christianity. Religion, like art, is inferior to philosophy as an exponent of the harmony between man and the absolute. In it the absolute exists as the poetry and music of the heart, in the inwardness of feeling. Hegel after expounding the nature of religion passes on to discuss its historical phases, but in the immature state of religious science falls into several mistakes. At the bottom of the scale of nature-worships he places the religion of sorcery. The gradations which follow are apportioned with some uncertainty amongst the religions of the East. With the Persian religion of light and the Egyptian of enigmas we pass to those faiths where Godhead takes the form of a spiritual individuality, z. c., to the Hebrew religion (of sublimity), the Greek (of beauty), and the Roman (of adaptation). Last comes absolute religion, in which the mystery of the reconciliation between God and man is an open doctrine. This is Christianity, in which God is a Trinity, because He is a spirit. The revelation of this truth is the subject of the Christian Scriptures. For the Son of God, in the immediate aspect, is the finite world of nature and man, which far from being at one with its Father is originally in an attitude of estrangement. The history of Christ is the visible reconciliation between man and the eternal. With the death of Christ this union, ceasing to be a mere fact, becomes a vital idea,—the Spirit of God which dwells in the Christian community.

The lectures on the History of Philosophy deal disproportionately with the various epochs, and in some parts date from the beginning of Hegel's career. In trying to subject history to the order of logic they sometimes misconceive the filiation of ideas. But they created the history of philosophy as a scientific study. They showed that a philosophical theory is not an accident or whim, but an exponent of its age determined by its antecedents and environments, and handing on its results to the future.

For ten years after Hegel's death his system remained the foremost intellectual phenomenon of the time. Besides Gans, Hinrichs, Henning, and Hotho, who have been already alluded to, the most prominent of his immediate disciples were Gabler, whose *Propædæutik* is a good introduction to Hegel; K. L. Michelet, one of the most ardent Hegelians, who is now (1879) on the point of completing a summary of the system; Daub and Marheineke, two theologians; and Göschel, whose *Aphorismen über nicht-Wissen und absolutes Wissen* elicited an appreciative review from Hegel. In æsthetics, where the school won some distinction, are the names of Schasler, Rosenkranz, and Vischer. Karl Rosenkranz, the literary champion of the system, has just ended a life devoted to its exposition; Erdmann still teaches in its spirit at Halle, as does Kuno Fischer at Jena. The last two have specially distinguished themselves by their histories of modern philosophy. With Michelet they form the more orthodox and conservative section of the school. The opposition to its doctrines was concentrated in the *Zeitschrift für Philosophie*, founded in 1837 by the younger Fichte with the help of Weiss; while Bencke and other followers of Herbart vigorously attacked its metaphysics and psychology. But the most notable outgrowth of Hegelianism was the so-called "Left," the critical and heterodox school of Feuerbach, Bruno Bauer, and Ruge. While Hegel had vindicated God as the subject of metaphysics, maintained the consonance of philosophy and theology, and elevated the state to sovereignty in ethics, the Left eliminated God from the system, exposed its alleged pantheistic or atheistic tendencies, and reasserted the supremacy of the individual in morals. To discuss the evolution of Hegelianism in this direction would almost be to write the history of modern German philosophy up to 1860. Hegelianism has now ceased to exist as an isolated system in Germany, though its spirit and method have leavened the whole mass of philosophic thought. Out of Germany, besides occasional admirers and disciples, it has attracted a considerable amount of general curiosity. In England it has stimulated philosophical thought, and probably suggested the correction of some national limitations; but few if any profess to accept the system in its integrity. Professor Vera of Naples is perhaps its most enthusiastic advocate on the Continent, whilst the *Journal of Speculative Philosophy* upholds its banner in America.

Bibliography.—Shortly after Hegel's death his collected works were published by a number of his friends, who combined for the purpose. They appeared in eighteen volumes in 1832, and a second edition came out about twelve years later. Volumes i.—viii contain the works published by himself; the remainder is made up of his lectures on the Philosophy of History, Æsthetic, the Philosophy of Religion, and the History of Philosophy, besides some essays and reviews, with a few of his letters, and the Philosophical Propædæutic.

For his life see Rosenkranz, *Leben Hegels*. Berlin, 1844; Haym,

Hegel und seine Zeit, Berlin, 1857; Köstlin, *Hegel in philosophischer, politischer, und nationaler Beziehung*, Tübingen, 1870; Rosenkranz, *Hegel als Deutscher National-philosoph*, Berlin, 1870, and his *Neue Studien*, vol. iv., Berlin, 1878.

For the philosophy, see Ruge's *Aus Früherer Zeit*, vol. iv., Berlin, 1867; Haym (as above). Trendelenburg (in *Logische Untersuchungen*), Kjuu (*Metaphysische Untersuchungen*), and C. Hermann (*Hegel und die logische Frage*, and other works) are noticeable as modern critics. Vera has translated the *Encyclopædic* into French, with notes; Bénard, the *Æsthetics*. In English Dr Stirling's *Secret of Hegel*, 2 vols., London, 1865, contains a translation of the beginning of the *Wissenschaft der Logik*; the "Logic" from the *Encyclopædic* has been translated, with prolegomena, by W. Wallace, Oxford, 1874; and large portions have been translated in the *American Journal of Speculative Philosophy*—especially by its energetic editor, W. T. Harris. (W. W.)

HEIBERG, JOHAN LUDVIG (1791–1860), Danish poet and critic, was the son of the political writer Peter Andreas Heiberg, and of the famous novelist, afterwards the Baroness Gyldenbourg-Ehrensvärd. He was born at Copenhagen, December 14, 1791. In 1800 his father was exiled, and he was taken by Rahbek and his excellent wife into their house at Bakkehuset. They found him, however, very difficult to manage, and about 1802 sent him back to his own family. His mother's marriage being by a state decree annulled, she married the Swedish baron Gyldenbourg-Ehrensvärd, keeping up, however, friendly correspondence with her first husband in Paris. In 1805 she describes, in one of these letters, the brilliant precocity of the young Johan. The latter proceeded to the university of Copenhagen in 1809. It was not needful that he should earn his bread, and accordingly his mother indulged for many years his extraordinary thirst for knowledge. In 1812 he visited Sweden, and made some long stay in Stockholm; he afterwards sent to his mother from Upsala the first important poem which he composed, *Hjemkomsten* (The Return Home), a piece of remarkable strength and brightness. In 1813 his first publication appeared, a romantic drama for children, entitled *The Theatre for Marionettes*. This was followed by *Christmas Jokes and New Year's Tricks* in 1816, *The Initiation of Psyche*, 1817, and *The Prophecy of Tycho Brahe*. These works attracted attention at a time when Baggesen, Oehlenschläger, and Ingemann possessed the popular ear, and were understood at once to be the opening of a great career. In 1817 Heiberg took his degree, and in 1819 went abroad with a grant from Government. He proceeded to Paris, and spent the next three years there, under his father's roof. In 1822 he published his drama of *Nina*, and was made professor of the Danish language at the university of Kiel. At this town he delivered a course of lectures, comparing the Scandinavian mythology as found in the *Edda* with the poems of Oehlenschläger. These lectures were published in German in 1827. In 1825 Heiberg came back to Copenhagen for the purpose of introducing the vaudeville¹ on the Danish stage. Meanwhile he was producing dramatic work of a more serious kind: in 1828 he brought out the national drama of *Elverhøi*, in 1835 the comedy of *The Elves*, and in 1838 *Fata Morgana*. In 1841 Heiberg published a volume of *New Poems*, containing "A Soul after Death," which is perhaps his masterpiece, "The Newly Wedded Pair," and other pieces. All this time he had been busily engaged in editing the famous journal, *The Copenhagen Flying Post*, which he founded in 1827 and continued until 1837. In 1831 he married Johanne Louise Pætges, the greatest actress that Scandinavia has produced. Heiberg's scathing satires at last began to make him very unpopular; and this antagonism reached its height when, in 1845, he published

¹ He composed a great number of vaudevilles, of which the best known are *King Solomon and George Hatmaker*, 1825; *April Fools*, 1826; *A Story in Rosenborg Garden*, 1827; *Kjæge Huskers*, 1831; *The Dances in Paris*, 1833; *No*, 1836; *Yes*, 1839; and *Emil's Beating Heart*, 1840.

his little malicious drama of *The Nut Crackers*. Notwithstanding this he received in 1847 the responsible post of director of the national theatre, for which indeed he was more eminently fitted than any other living person. He filled it for seven years, working with great zeal and conscientiousness, but was forced by intrigues from without to resign it in 1854. His health was much disturbed by these attacks, and he retired into private life. Heiberg died at Bonderup, near Ringsted, on the 25th of August 1860.

It has been said that "the average cultivated Dane nowadays is very much what Heiberg has made him." His influence upon taste and critical opinion was greater than that of any writer of his time, and can only be compared with that of Holberg in the 18th century. Most of the poets of the Romantic movement in Denmark were very grave and serious; Heiberg added the element of humour, elegance, and irony to the dignity of Oehlenschläger, the pathos of Ingemann, and the passion of Hertz. His versification was refined and exact, and his very best pieces are those in which he mingles rich lyrical expression with what is satirical or purely ludicrous. The works of Heiberg were collected, in 11 vols., in 1861-62.

HEIDE, a town of Prussia, chief town of the circle of North Ditmarsh, province of Schleswig-Holstein, is situated on a small plateau which stands between the marshes and moors bordering the North Sea, 35 miles N.N.W. of Glückstadt. It is the seat of a provincial office, a court of justice, and a head tax office, and possesses tobacco and cigar manufactories, a tannery, and a rope work. Heide in 1447 became the capital of the Ditmarsh peasant republic, but on the 13th June 1559 it was the scene of the complete defeat of the peasant forces by the Danes and the duke of Schleswig-Holstein. The population in 1875 was 6772.

HEIDEGGER, JOHN HENRY (1633-1698), theologian, was born at Bärenschwiel, in the canton of Zurich, Switzerland, on July 1, 1633. He began his studies in his native country, and completed them at Marburg and Heidelberg. Becoming doctor of philosophy at the latter university, he soon afterwards was appointed professor extraordinarius of Hebrew, and later of philosophy. From Heidelberg he was in 1659 summoned to Steinfurt to fill the chair of theology and ecclesiastical history, and in the same year he became doctor of theology of Heidelberg. In 1660 he revisited Switzerland; and, after marrying, he travelled in the following year over Holland. The war at this time having dispersed the students from Steinfurt, Heidegger returned in 1665 to Zurich, where he was immediately elected professor of moral philosophy. Two years later he succeeded Hottinger in the chair of theology, which he occupied till his death, January 15, 1698. Heidegger was the principal author of the *Formula Consensus Helvetica* in 1675, which was designed to unite the Swiss Reformed churches, but had an opposite effect.

His writings are largely controversial, and are in great part levelled against the Roman Catholic Church. The chief are *De Historia sacra Patriarcharum Exercitationes selectæ*, 1667-1671; *Dissertatio de Pergrinationibus Religiosis*, 1670; *De Rationi Studiorum, opuscula aurea*, &c., 1670; *Historia Papatus*, 1684; *Tumulus Concilii Tridentini*, 1690; *Exercitationes Biblicæ*, 1700, with a life of the author prefixed; *Corpus Theologicæ Christianæ*, 1700; and lives of Hottinger, 1667, and Fabricius, 1698. His autobiography appeared in 1698, under the title *Historia Vitæ J. H. Heideggeri*.

HEIDELBERG, a German university city in the Baden circle and jurisdiction of the same name, lies in 49° 24' N. lat. and 8° 41' 32" E. long., at the foot of the Castlehill, a spur of the Königsstuhl on the south bank of the Neckar, about 12 miles from the junction of that river with the Rhine. The situation of the town is one of romantic beauty.

Plan of Heidelberg.

Placed at the opening of the winding Neckar valley, it has behind it and before it lofty hills covered with vineyards and forests. Between these the Neckar rushes swiftly along. To the left the country opens out into the broad Rhine plain, cultivated like a garden, and bounded by distant and hardly perceptible mountains. The town primarily consists of one long narrow street, the Hauptstrasse, which begins near the station of the Main-Neckar railway on the west, and runs parallel to the river with continuations for a distance of about 2 miles to the Karlsthor (where there is a smaller station) on the east. To the south of this the Anlage, a pleasant promenade flanked with fine houses and gardens, leads directly from the chief station to the centre of the town. A number of smaller streets run up from the river, intersecting the

Hauptstrasse at right angles. On the other side of the Neckar the Heiligenberg, a vine-clad hill wooded towards the summit, crowned with the ruins of an old chapel, rises abruptly from the river bank. About half-way up the hill the Philosophenweg, a famous road, runs from the Hirschgasse opposite the Karlsthor to the suburb of Neuenheim, opposite the railway station. At this point the Neckar valley ceases, and the river flows slowly onward in the almost level Rhine plain. Of late years the town has grown very much towards the west end on both sides of the river. The additions have been almost entirely of the better class of houses.

Of the churches the chief are The Peterskirche (founded before 1392), where Jerome of Prague in 1460 expounded the Reformed doctrines; the Heiliggeistkirche.

erected at the beginning of the 15th century, of which the nave is used for Protestant, the choir for Old Catholic worship; and the Jesuitenkirche, with sumptuously decorated interior. All these are built in the Gothic style. The rathaus, the museum, and the university (1712) are large but common-place erections. Two handsome bridges cross the Neckar. That to the east, opposite the castle (built 1788), is adorned with a gateway, and with statues of Minerva and the elector Charles Theodore of the palatinate; the other (built 1877) unites Heidelberg and Neuenheim. In the west part of the town there is a bronze statue of Field-Marshal Prince Wrede (1767-1838), erected in 1860 by Louis I., king of Bavaria. The chief building at Heidelberg, and indeed its chief attraction for strangers, is the famous castle which overhangs the west part of the town. It is situated on the Castlehill, more properly called the Jettenuhel, 330 feet above the Neckar. Though now a ruin, yet its extent, its magnificence, its beautiful situation, its interesting history, render it by far the most noteworthy, as it certainly is the grandest and largest, of the old castles

with a large number of imposing statues. Within this is the chapel, and behind it the Altan (1610), or castle balcony, which directly overhangs the town and from which the finest of Heidelberg views is obtained. The castle contains an interesting antiquarian museum¹ formed by the Count Graimberg, and the celebrated Great Tun, which was built in 1751, but has been only used on one or two occasions. Its capacity is 49,000 gallons. There is a castle garden, spacious and well laid out.

The university of Heidelberg is the oldest in the German kingdom. It was founded in 1356 by the elector Rupert, but it was not till 1386, when it obtained papal sanction, that its real life begins. It was constructed after the type of Paris, had four faculties, and possessed numerous privileges. Marselius von Inghen was its first rector. Frederick the Victorious, Philip the Upright, and Louis V. respectively cherished it. Otto Henry gave it a new organization, further endowed it, and founded the library. At the Reformation it became a stronghold of Protestant learning. The famous Heidelberg catechism was drawn up by its theologians. Then the tide turned. Damaged by the Thirty Years' War, it led a struggling existence for a century and a half. A large portion of its remaining endowments were cut off by the peace of Lunéville (1801). In 1803 however the elector Charles Frederick raised it anew, and reconstituted it under the name of "Ruperto-Carolina." At present (1880) it has 38 ordinary and 26 extraordinary professors. The students number about 500 in winter, and from 800 to 900 in summer. A very large proportion are English and Americans. The library was first kept in the choir of the Heiliggeistkirche, and then consisted of 3500 MSS. In 1623 it was sent to Rome by Tilly, and stored as Bibliotheca Palatina in the Vatican. It was afterwards taken to Paris, and in 1815 was restored to Heidelberg. In 1703 the new library was founded; it has now nearly 300,000 volumes, besides many valuable MSS. Among the other university institutions are the academic hospital, the maternity hospital, the physiological institution, the chemical laboratory, and the zoological museum.

The other educational foundations are a gymnasium and a burgher and a real school. There is a small theatre (closed during the summer months) and a Kunstverein. The manufactures of Heidelberg are unimportant. The inhabitants chiefly support themselves by supplying the wants of a large and increasing body of foreign permanent residents, of the considerable body of tourists who during the summer pass through the town, and of the university students. The population of the town and outlying suburbs was 19,988 in 1871, and 22,334 (or including Neuenheim, 23,918) in 1875. About one-third are Catholics. The town is well lighted, and is supplied with excellent water from the Wolfsbrunnen.

Heidelberg at an early period was a fief of the bishop of Worms, but the rulers of the palatinate came more and more to reside there, till Count Otho of Wittelsbach (1228-1253) made it the capital of the palatinate, and this it continued to be for nearly six centuries. As Heidelberg was one of the great centres of the Reformed faith, it suffered severely in the Thirty Years' War. In 1622 it was sacked by Tilly, and in 1633 was taken by the Swedes. In 1634 it was beleaguered by the Bavarians. In 1635 it was occupied by the imperial forces under Gallas. At the peace of Westphalia (1648) Charles Louis, son of Frederick V., was restored, and he did much to raise the castle, the university, and the town. In 1688, and again in 1693, it was sacked by the French. On the last occasion, so thorough was the work of destruction that only one house—a quaintly decorated erection in the Marktplatz now used as an inn—escaped. In 1720 Charles Philip removed his court to Mannheim, and in 1803 the town became part of the grand duchy of Baden. On 5th March 1848 was held the famous Heidelberg assembly, at which steps were taken that led to the German revolution of that year.

Ground-Plan of Heidelberg Castle.

of Germany. It was begun about the end of the 13th century. Elector Rupert greatly improved it, and erected the Rupert's building in the early part of the 15th century; succeeding electors of the palatinate did much for it, especially Frederick V., the unfortunate king of Bohemia. It suffered greatly during the Thirty Years' War, but was restored by Charles Louis (1650-1680). It was dismantled by the French in 1689, and again in 1693. In 1764 it was struck by lightning and its destruction completed. The castle as it at present stands is a square edifice formed of several distinct structures built round a large court-yard; the entrance is on the south side. The court-yard contains a fountain adorned with four granite pillars brought from Charlemagne's palace at Ingelheim. The chief parts of the castle are Rupert's building (about 1400) on the left; Otto Henry's building (1556) on the right, "the finest example of Renaissance architecture in Germany," a lofty building of which the front is richly decorated; Frederick's building (1601), the finest part, forming the northern portion of the whole, and adorned

¹ This museum was acquired by the town in 1879.

Of the numerous topographical works on Heidelberg, those of Fickler (1863) and Oncken (2d ed., 1874) may be mentioned. The *Wegweiser durch Heidelberg* (1879) supplies a briefer and more popular account. The university annals are told in Hautz's *Geschichte der Universität Heidelbergs* (2 vols., 1863-64), and the very interesting history of the library in Wilken's *Geschichte der Bildung, Beraubung, und Vernichtung der alten Heidelberger Büchersammlung* (1817), and in Ruland's *Zur Geschichte der alten nach Rom entführten Bibliothek zu Heidelberg*, Leip., 1856. The *Heidelberger Jahrbücher* (1817-73) contain a mass of interesting and important information as to the history of the town and castle. (F. WA.)

HEIDELOFF, KARL ALEXANDER VON (1788-1865), a German architect, was the son of Victor Peter Heideloff, a painter of some reputation, and was born at Stuttgart 2d February 1788. He studied at the art academy of his native town, and after following the profession of an architect for some time at Coburg was in 1818 appointed city architect at Nuremberg. In 1822 he became professor at the polytechnic school, and some years later he was chosen conservator of the monuments of art. Heideloff devoted his chief attention to the Gothic style of architecture, and the buildings restored and erected by him at Nuremberg and in its neighbourhood attest both his original skill and his purity of taste. He also achieved some success as an historical painter. He died at Hassfurt 28th September 1865.

Among his writings on architecture are *Die Lehre von den Säulenordnungen*, 1827; *Der Kleine Vignola*, 1832; *Nürnberg's Baudenkmäler der Vorzeit*, 1838-43; and *Die Ornamentik des Mittelalters*, 1838-42.

HEILBRONN, a town of Württemberg, in the circle of the Neckar, is situated in a pleasant and fruitful valley on the Neckar, and at the junction of several railways, 26 miles N. of Stuttgart. It is the seat of a circle court, a jury court, a superior tribunal, a head tax office, and a chamber of commerce. In the older part of the town the streets are narrow, and it contains a number of high turreted houses with quaintly adorned gables. The old fortifications have now been demolished, and their site is occupied by promenades, outside of which are the more modern parts of the town with wide streets and many handsome buildings. The principal public buildings are the church of St Kilian, in the Gothic and Renaissance styles, begun in 1019 and completed in 1529, with an elegant tower 210 feet high, a beautiful choir, and a finely carved altar; the town-house, founded in 1540, and possessing a collection of interesting documents; the house of the Teutonic knights, now used as barracks; the Catholic church of St Joseph; the tower on the Neckar, in which Götz von Berlichingen was confined in 1525; the synagogue, the prison, and the hospital. The educational establishments include a gymnasium, a real-school of the second order, an agricultural school, and a female school of industry. The town in a commercial point of view is the most important in Württemberg, and possesses an immense variety of manufactures, of which the principal are gold, silver, steel, and iron wares, machines, sugar of lead, white lead, vinegar, beer, eau de Cologne, sugar, tobacco, soap, oil, cement, sulphuric acid, tartaric acid, artificial manure, glue, soda, tapestry, thread, and cloth. Grapes, fruit, vegetables, and flowering shrubs are largely grown in the neighbourhood, and there are large quarries for sandstone and gypsum. By means of the Neckar a considerable trade is carried on in wood, bark, leather, agricultural produce, fruit, and cattle. The population in 1875 was 21,209.

Heilbronn occupies the site of an old Roman settlement. Its name—originally Heiligbronn or holy spring—was bestowed on it by Charlemagne from a spring of water which until 1857 was to be seen issuing from under the high altar of the church of St Kilian. In 1225 Heilbronn became a free imperial city. It was frequently besieged during the Middle Ages, and it suffered greatly during the Peasants' War, the Thirty Years' War, and the various wars with France. In 1803 it came into the possession of Württemberg.

HEILIGENSTADT, a town of Prussian Saxony, government district of Erfurt, is situated on the Leine and on the railway from Halle to Cassel, 32 miles E.N.E. of Cassel. It possesses an old castle, formerly belonging to the electors of Mainz, one Evangelical and two Catholic churches, a Catholic gymnasium, a Catholic normal school, two orphanages, and an infirmary. The principal manufactures are woollen wares, cigars, paper, bone dust, and needles. The population in 1875 was 5193.

Heiligenstadt is said to have been built by Dagobert, and was formerly the capital of the principality of Eichsfeld. In 1022 it was acquired by the archbishop of Mainz, and in 1103 it came into the possession of Henry the Proud, but when Henry the Lion was placed under the ban of the empire it again came to Mainz. It was destroyed by fire in 1333, and was captured in 1478 by Count Henry the Young of Schwarzburg, and in 1525 by Duke Henry of Brunswick. In 1803 it came into the possession of Prussia.

HEILSBERG, a town of Prussia, capital of a circle in the government district of Königsberg, is situated at the junction of the Simser and Alle, 38 miles S. of Königsberg. It has one Evangelical and two Catholic churches, and an old castle formerly the seat of the prince-bishops of Ermland, but now used as an infirmary. The principal industries are cloth-weaving, yarn and thread spinning, dyeing, and brewing, and there is considerable trade in grain. The population of the town in 1875 was 5762.

The castle founded at Heilsberg by the German knights in 1240 became afterwards the property of the bishops of Ermland, who in 1306 made it their seat—an honour which it retained for 500 years. On the 10th June 1807 a battle took place at Heilsberg between the French and the Russians under Benningsen, which, although the French who attacked thought it prudent to withdraw before victory declared for either side, resulted on the following day in the retreat of the Russians.

HEILSBRONN, or **KLOSTER-HEILSBRONN**, a market-village in the Bavarian government of Middle Franconia, with a station on the railway between Nuremberg and Ansbach. In 1871 it had only 998 inhabitants, but in the Middle Ages it was the seat of one of the great monasteries of Germany. This foundation, which belonged to the Cistercian order, owed its origin to Bishop Otto of Bamberg in 1132, and continued to exist till 1555. Its sepulchral monuments, many of which are figured by Hocker, *Heilsbronnischer Antiquitätenschatz* (Ansbach, 1731-40), were of exceptionally high artistic interest, ten burgraves of Nuremberg (it was their hereditary burial-place), three electoral princes, five margraves of Brandenburg, and many other persons of note having been laid to rest within its walls. The buildings of the monastery have all disappeared, with the exception of the fine church, restored between 1851 and 1866. The "Monk of Heilsbronn" is the ordinary appellation of a didactic poet of the 14th century, whose *Seven Degrees*, *Daughter of Syon*, and *Life of Saint Alexius* were published by Merzdorf at Berlin in 1870.

See "Notae Halesbrunnenses" and "Annales Halesbrunnenses," in Pertz, *Mon. Germ. Hist.*, vol. xvi.; Muck, *Beiträge zur Gesch. von Heilsbronn*, Ansb., 1859; Rehm, *Ein Gang durch und um die Münster-Kirche zu Kloster-Heilsbronn*, Ansb., 1875; and Stillfried, *Kloster-Heilsbronn, ein Beiträge zu den Hohenzoll. Forschungen*, Berlin, 1877.

HELM, FRANÇOIS JOSEPH (1787-1865), French painter, belongs to that group of painters in whose works we find the special characteristics of the Restoration. Born at Belfort on 16th December 1787, he early distinguished himself at the École Centrale of Strasbourg, and in 1803 entered the studio of Vincent at Paris. In 1807 he obtained the first prize, and in 1812 his picture of *The Return of Jacob* (Musée de Bordeaux) won for him a gold medal of the first class, which he again obtained in 1817, when he exhibited, together with other works, a *St John*—bought by Vivant Denon. In 1819 the *Resurrection of Lazarus* (Cathédral Autun), the *Martyrdom of St Cyr* (St

Gervais), and two scenes from the life of Vespasian (ordered by the king) attracted attention. In 1823 the re-erection of the Royal Tombs at St Denis, the Martyrdom of St Laurence (Notre Dame), and several full-length portraits increased the painter's popularity; and in 1824, when he exhibited his great canvas, the Massacre of the Jews (Louvre), Heim was rewarded by the legion of honour. In 1827 appeared the King giving away Prizes at the Salon of 1824 (Louvre—engraved by Jazet)—the picture by which Heim is best known—and Saint Hyacinthe. Heim was now commissioned to decorate the Gallery Charles X. (Louvre), work for which he was thought eminently fit. Like many other painters of this period, Heim retained only enough of the high-pitched ideal of David to make an awkward contrast with the lively colour and movement by which he tried to give interest to his subjects, and with the emptiness of form and expression which resulted from the hasty execution necessitated by the vast number of his commissions. Ridiculed by the romantists, Heim maintained his position, and replaced Regnault at the Institute in 1834, shortly after which he commenced a series of drawings of the celebrities of his day, which are of much interest. His decorations of the Conference room of the Chamber of Deputies were completed in 1844; and in 1847 his works at the Salon—*Champ de Mai* and *Reading a Play at the Théâtre Français*—were the signal for attacks renewed with great violence. Yet something like a turn of opinion in his favour took place at the exhibition of 1851; his powers as a draughtsman and the occasional merits of his composition were recognized, and toleration extended even to his colour. Heim was awarded the great gold medal, and in 1855—having sent to the Salon no less than sixteen portraits, amongst which may be cited those of Cuvier, Geoffroy de St Hilaire, and Madame Hersent—he was made officer of the legion of honour. In 1859 he again exhibited a curious collection of portraits, sixty-four members of the Institute arranged in groups of four; and six years later, on 29th September 1865, he died, at the age of seventy-eight. Besides the paintings already mentioned, there is to be seen in Notre Dame de Lorette (Paris) a work executed on the spot; and the museum of Strasburg contains an excellent example of his easel pictures, the subject of which is a Shepherd Drinking from a Spring.

HEINE, HEINRICH (1799–1856), poet and journalist, was born, according to the most trustworthy accounts, on the 13th December 1799, at Düsseldorf, of Jewish parents. His father, after various vicissitudes in business, had finally settled in that town, and his mother, who seems to have possessed much energy of character, was the daughter of a physician of the same place. Heine received the rudiments of his education at the gymnasium or *lycée* (as it was called during the foreign occupation) of his native town, and, although not an especially apt or diligent pupil, he acquired while there a good knowledge of French and English,—he tells us that *Gulliver's Travels* in the original was one of the favourite books of his childhood,—as well as some tincture of the classics and Hebrew. But if the influence upon him of his teachers and their teaching was unimportant, not so that of the public events amid which he grew up. His early years coincided with the most brilliant period of Napoleon's career; and the boundless veneration which he is never tired of expressing for the emperor throughout his writings shows that his true schoolmasters were rather the drummers and troopers of a victorious army than the Jesuit fathers of the *lycée*; while, if to the vivid personal impression produced upon him by the pomp and circumstance of the imperial garrison in his birthplace there be added the public, and in a manner national, enthusiasm for Napoleon which he must

often have heard vented by his elder co-religionists—who hailed the conqueror as a temporal Messiah—the weighty bearing of his boyhood upon his subsequent fortunes becomes fully apparent. Upon his quitting school, attempts were made to engage him in commerce, but his father and uncle, the latter a wealthy banker of Hamburg, soon perceived that he was bent upon travelling a different path from that which they had followed. It speaks well for both these men that they should have refrained from coercion upon making this discovery; and Solomon Heine, the banker, at once gave his nephew an earnest of the generous treatment the latter was subsequently to experience at his hands, for he came forward with money to enable his young kinsman to go to a university, his sole stipulation being that his protégé should study with the view of entering the legal profession. Heine gladly accepted his uncle's terms, and entered the university of Bonn in the spring of 1819. During his stay there he was an eager student; but the subjects to which he devoted himself had no connexion with the profession which had been chosen for him. He seems to have attended no lectures save those on literature and history—notably A. W. von Schlegel's; and he not long afterwards acknowledged his obligations to Schlegel by dedicating a sonnet to him—a tribute which he recalled in later days by a wanton and outrageous attack upon the veteran critic in *Die Romantische Schule*. Why Heine left Bonn does not clearly appear, but it is at Göttingen that we find him in the autumn of 1820. His stay here was even shorter than at Bonn. In February 1821 the authorities of the "Georgia Augusta" rusticated him for some infraction of the duelling laws. Although from these beginnings Heine's academical career promised to pursue no very even course, he nevertheless determined, after his residence at Göttingen had been cut short, to seek a third university; and it was to Berlin that he now repaired, where Hegel was at the zenith of his renown. Whether or not the lectures of this philosopher benefited him in any way—by giving him, for instance, as some have supposed, a certain dialectical precision of style—he has himself confessed that he seldom understood them; and in after years Hegel's ultra-conservatism and orthodoxy made him the constant butt of his former pupil's ridicule and sarcasm. But the interest of Heine's life in Berlin was social and not academic. He enjoyed the privilege of mixing in the best literary circles of the capital. He was on terms of intimacy with Varnhagen von Ense and his wife, the celebrated Jewess, Rachel, and at their house—the rendezvous of Germany's genius and learning—he frequently met such men as the Humboldts, Hegel himself, and Schleiermacher; while he lived on a still more familiar footing with a number of his own co-religionists, who, without having acquired European reputation, were men of varied and approved abilities. In an atmosphere of such geniality as this his gifts were rapidly displayed. He began ere long to contribute poems to the *Berliner Gesellschafter*, many of which were subsequently incorporated in the *Buch der Lieder*, and in 1822 a volume came from the press entitled *Gedichte von Heinrich Heine*, his first avowed act of authorship. He was still further employed at this time as the correspondent of a Rhenish newspaper, as well as in completing his tragedies *Almansor* and *William Ratcliff*, which were published in 1823 with small success. He was now, indeed, fairly embarked upon his literary course. But he was still largely dependent upon his uncle; and in order so far to fulfil his engagements towards his benefactor, he returned to Göttingen in 1825, and shortly afterwards took his degree in law, having previously qualified himself for practice by publicly professing Christianity.

This act of "apostasy," as it has been called, calls for something more than a mere passing reference; for it not

only laid Heine open to contumely while alive, but has provoked adverse criticism of special severity since his death. That he was guilty of "apostasy" is no doubt verbally true; but there are two circumstances in this connexion which should always be remembered. The one is that Heine was wholly wanting in the religious sense—that he never was a Jew save nominally and by the accident of birth—so that he cannot, with any real propriety, be said to have forsaken the creed of his race; the other, that his family, by encouraging him to adopt a profession which could not be entered except by the gateway of "apostasy," tacitly left him free to take that step. In short, Heine's "apostasy" was a purely secular act; and, although there will doubtless be found many to stigmatize him all the more blackly for this very reason, candour appears rather to require that this change of faith, if such it can be called, should be classed as one of his most venial offences, being the plainly outward act of one who throughout life made himself peculiarly obnoxious to the imputation of malice and bad-heartedness.

Heine seems never to have made any serious attempt to practise law. His life from the year 1826 until his death was devoted entirely to literature, and more especially to journalism, which alone indeed was the main source of his income for many years. At first he lived in Hamburg, and then it was that, besides the *Buch der Lieder*, the earlier portions of the *Reisebilder* appeared, both of which, but particularly the latter, at once created an immense sensation throughout Germany, not only among the youthful and enthusiastic, who found their own sentiments expressed by the new writer with the happiest audacity, but amongst such dignified and *rangés* personages as Metternich and Gentz. In 1827 Baron Cotta, the Bavarian publisher, offered Heine, who had risen at a bound into celebrity, the joint-editorship of the *Allgemeine Politische Annalen*. The young author accepted the offer, and betook himself to Munich in the winter of that year, after having paid a visit to London, where he found every person and everything detestable save Canning and his policy—and it may be said here in passing that a most violent hatred of England forms a marked feature of all Heine's writings. He remained for a considerable period in the South-German capital, and it was owing, not to any disagreement with his employer, but to the demands of the court of Prussia, which was not long of taking umbrage at his freedom of opinion, that his editorial function ceased so abruptly as it did. What the secret history of the next two or three years of his life was—whether from the very first he really was an object of especial disfavour at Berlin, or whether, as is quite as likely, taking his vanity and love of publicity into account, he exaggerated his powers of offence beyond the endurance of the Government there, and forced it into what seemed a petty persecution—he presently perceived that he must either quit Germany altogether or prepare for a life-time perhaps of fortress-imprisonment. He did not long hesitate between these two alternatives; and on the 1st of May 1831 Heinrich Heine left his native land for Paris, where he lived for the rest of his life, only once recrossing the Rhine, in 1843.

Just as his adoption of Christianity has led to Heine's being pronounced "apostate," so has his self-expatriation caused German writers to denounce him as "renegade." But the one accusation is as groundless as the other. In the first place Heine was a Jew, in spite of his Christianization, and cannot therefore rightly be called a "renegade" against Germany—least of all when the degraded social and political status of his race in that country at the date of his emigration is recollected. Then again his writings were systematically subjected to the cruellest mutilations, and it is tolerably certain that had he remained in the "Fatherland," he would sooner or later have been

deprived of all power of public speech. Was it any wonder, seeing that he had adopted the profession of letters, that he should have turned his back upon such a prospect? He at any rate was the best judge; and it ill becomes Germans to call him "renegade," when, had he continued to tarry among them, their literature would probably have suffered an irreparable loss. At the same time, and for the same reasons, it is equally inept to assert that he was in the essential qualities of his mind a Frenchman who gravitated towards Paris by a sort of intellectual necessity. The necessity (to use that word) was physical. Heine would never have left Germany could he have freely expressed his opinions there.

After settling in his new home, where his life for many years must have been as gay and brilliant as latterly it was sad and sombre, and where he speedily became more or less intimate with such writers as Balzac, Dumas the elder, George Sand, Victor Hugo, and Théophile Gautier, Heine devoted himself more exclusively than ever to journalism; and from 1831 until 1847, he was an active and indefatigable publicist. The two series of papers entitled *Französische Zustände* and *Lutetia* contain a selection from his press-contributions during these years; and even at this date they well repay perusal, not only by the brilliancy of wit and elegance of style which they possess in common with almost all his writings, but also by the remarkable sagacity of their political *aperçus*. Alongside of this main stream of journalism, he also kept up a subsidiary current of literature in its more proper sense—although it may be said that all his writings are of an occasional nature—and to this we owe the *Salon* (1833-39), which comprises among other pieces a series of articles, "Zur Geschichte der Religion und Philosophie in Deutschland," which had originally appeared in the *Revue des deux Mondes*, and in which Heine came forward as the introducer of German thought to the reading world of Paris. The *Salon* also contains several admirable papers in art-criticism, and a strange, fragmentary medley of sentiment and satire, in its author's most characteristic vein—"Die Florentinische Nächte." To this period, too, belongs *Die Romantische Schule*, to which reference has already been made, and the substance of which is sufficiently indicated by its name. In 1839 *Shakespeare's Mädchen und Frauen* appeared—Heine acting in this slight work as cicerone through a gallery of Shakespeare's heroines. The year 1840 was signalized by the publication of *Heinrich Heine über Ludwig Börne*, a brochure of the wittiest and most trenchant satire, in which the German refugees in Paris—a fraternity whom Heine always anxiously avoided—were far more severely handled than was the defunct agitator whose name it bore, and who, it may be noted, was himself a Jew. In 1844 *Deutschland, ein Wintermärchen*, came forth—the result of the visit to Germany which has been alluded to as the sole journey of the kind which Heine undertook; and this effusion may be ranked, along with a similar performance, *Atta Troll* (1846), as belonging to his most inferior writings. It was in 1848 that Heine, in the very hey-day of his activity, and with gigantic projects seething within him for the foundation of a journal, was suddenly prostrated by the disease which finally carried him off, though not before it had confined him for seven years upon the "mattress-grave" of mournful notoriety. His sufferings throughout that time are reported to have been frequently excruciating, and he at length grew so habituated to the use of opium that the very largest doses failed to afford him relief. But when his malady—a softening of the spinal cord—allowed him a respite, his intellect was as clear and vivacious as ever; and it is to these closing years of his life, harassing as they were, that we are indebted for the finest and most finished of all his poems—for the two collections, that is to say,

Romanzero (1851) and *Neueste Gedichte* (1853-54), as well as for the various pieces posthumously published in *H. Heine's Letzte Gedichte und Gedanken*. It was from his "mattress-grave" too that the dying man put forth his *Geständnisse* or *Confessions*, the psychological interest of which is very great, whatever their claim to trustworthiness may be. Heine bore the misery of his protracted death-bed with fortitude, nay, with cheerfulness, assiduously attended by his wife Mathilde, and towards the end by that mysterious lady whom he called "Die Mouche," and who was, it now appears, a Madame Krinitz; and there are many anecdotes on record of his bearing in the midst of his trials—and heavier trials seldom fell to the lot of man—which go far to prove that he possessed a healthy *fond gaillard*, for which his writings are scarcely likely to gain him credit. He died on the 17th February 1856 in Paris, in the Rue d'Amsterdam, and lies buried in the cemetery of Montmartre.

We have called Heine "poet and journalist"; but his reputation has, naturally enough, now come to rest almost exclusively upon his poetry, and above all upon his songs—the *Buch der Lieder* having passed through upwards of twenty-five editions. This great popularity may no doubt (and especially in foreign countries) be attributable, to a certain extent, to the singular good fortune which has wedded to very many of these songs the music of such composers as Schumann and Mendelssohn. But still, when all deductions upon this score are made,—and the true view of the matter probably is that the poet and his composers are mutually obliged,—the fact remains that Heine is one of the great song-writers of the world, not unworthy of a place beside Burns and Béranger, although far less masculine and passionate than the one, and far less jovial and debonaire than the other. The intense individualism which prevented him from ever becoming a literary artist in any other department—his dramas and essays in fiction are worthless—stood him in excellent stead in the lyric field,—was a positive and essential strength indeed, for, after all, a song to appeal to men's hearts must be an utterance of personal experience. And this condition is amply fulfilled in the *Buch der Lieder*, the greater portion of which was the direct outcome of a sentiment entertained by the poet for one of his cousins—a sentiment, by the way, which has been alluded to by German writers as a mere *Cousinenschwärmerei*, while others (not Germans) have affirmed that all Heine's bitterness and cynicism in after life arose from its having remained unrequited. On the whole, Heine as a song-writer is a fit descendant of Walther von der Vogelweide and those old *Minnesänger* who of yore assembled in the halls of princes, and recounted their sorrows and their joys—of those nameless bards, too, who sang the *Volkslieder*; and when all his other writings are forgotten, he will be remembered by such imperishable gems as "Die Rose, die Lilie, die Taube, die Sonne;" "Auf Flügeln des Gesanges;" and "Du bist wie eine Blume." There is much, too, of great beauty in many of his ballads and narrative pieces; witness among others, "Spanische Atriden," "Die Prinzessin Sambat," "Jehuda-ben-Halevy," "Böses Geträume"—a piece of the most exquisite pathos and simplicity—and "Die Insel Bimini." But too often, no matter how sweet a chord is struck at the beginning, a dissonance creeps in, to end in a crashing discord, and the outraged reader starts like one who should suddenly see Romeo and Juliet fall to grimacing and squeaking like Punch and Judy. Heine's confession that poetry was no more than his "holy plaything" would have been entitled to our unqualified acceptance had he omitted the adjective.

But when we turn to his prose-writings—to his "journalism," that is to say, for, as we have remarked, almost all his prose falls under this category, in its widest acceptation

—we see the man Heine indeed, not perhaps, as he was ambitious of being regarded by posterity, in the full panoply of a "soldier of human emancipation," but at any rate as no contemptible assailant of obscurantism and philistinism. Beside such a redoubtable champion of the catholic reason of mankind as Lessing "of the ponderous battle-axe," he looks somewhat small, it is true, and his rapier somewhat gimcrack. But ridicule will often reach whither heavier weapons cannot, and pierce the elephantine hide of pedantry and dulness, after these have been attacked in vain by battering-rams; and Heine was a master of it. The worst is that in unscrupulous hands—and no one was more unscrupulous than he—it may be turned to illegitimate uses, and come to be indulged in finally for its own sake. How easily Heine became the slave of his propensity in this direction may be seen in the two works—which seem his best and most characteristic writings, notwithstanding—*Zur Geschichte der Religion und Philosophie in Deutschland* and *Die Romantische Schule*. Both these abound in the most irreverent passages, especially the former, wherein such philosophers as Kant, Fichte, and Schelling scarcely serve a higher purpose than to be used as pegs whereon the writer may hang his jests. And admirable these are. Nothing can be better, for instance, than his account of how Kant (who is parenthetically described as a man whom Nature intended to sell coffee and sugar across a counter) came to postulate a Deity in his practical, after having exploded that idea in his theoretical, system. He did this, says Heine (most adroitly hitting one of the chief *opprobria*, scientifically regarded, of the critical philosophy), for the sake of his old man-servant Lampe, who looked so dismally at the conclusions of the Pure Reason that the philosopher was moved to compassion! The *Romantische Schule*, being concerned for the most part with its author's contemporaries, is far more virulent than the treatise just mentioned, but equally happy; and it aimed a death-blow at a school which rivalled the wildest and most licentious ravings of a Monk Lewis and the most stilted horrors of an Ann Radcliff. And here it may be said, in connexion with the attack upon Schlegel occurring in this essay, that Heine's onslaughts were always open and above-board, unmerciful and sometimes grossly brutal as they were. He was a literary swashbuckler, it may be (though that term is singularly inapplicable to one who wrote in such a style), but he was neither a literary assassin nor a literary ghoul. Even his attack upon Börne was really aimed, as we have said, at men who were alive to resent it; and it was resented, though from a strange quarter. Börne's widow's husband challenged Heine, and the latter was slightly wounded in the encounter.

Of the *Reisebilder*, Heine's most voluminous and best-known prose work, and that which originally gave him fame, small space remains to speak. But if we except its first and third books, it has been greatly overrated. It is easy to understand the popularity it acquired upon its first appearance, falling as it did like a breath of genuine life upon a land well-nigh asphyxiated by high art and the "Hübsch-Objectiv"—but nowadays, notwithstanding its undoubted mirth-provoking qualities, it chiefly serves to point out the gulf which was fixed between its author and him who took the *Sentimental Journey*. The most that can be said for it is that Sterne might have written it had he been a German Jew.

The best edition of Heine's works is that published by Hoffmann and Campe, *Heinrich Heine's Sämmtliche Werke*, 20 vols., Hamburg, 1865. Another edition has appeared in America, *Heinrich Heine's Sämmtliche Werke*, in 7 vols. *Heinrich Heine's Leben*, by Adolph Strodtmann, Berlin, 1870, is the only Life of Heine entitled to consideration, although the pleasure of reading it is certainly marred by its length. A biography of the poet has also appeared in England, *Life and Opinions of Heinrich Heine*, by W. Stigand,

1876. Mr Matthew Arnold has, in his *Essays in Criticism*, handled Heine with his acoustomal grace and felicity. Mention may also be made of *Wit, Wisdom, and Pathos of Heinrich Heine*, by J. Snodgrass, London, 1879, a collection of extracts from Heine's works in an English dress. A translation, *Heine's Poems, Complete*, by Edgar A. Bowring, C.B., was issued in Bohn's Standard Library. His prose works have not as yet received adequate renderings, although a version of the *Reisbilder* has been put forth in America. (J. W. F.)

HEINECCIUS, JOHANN GOTTLIEB (1681-1741), a celebrated jurist, was born 11th September 1681 at Eisenberg. He studied theology at Leipsic and law at Halle; and at the latter place he was appointed in 1713 professor of philosophy, in 1718 extraordinary, and in 1720 ordinary professor of jurisprudence. He subsequently filled legal chairs at Franeker in Holland and at Frankfort, but finally returned to Halle in 1733 as professor of philosophy and jurisprudence. He died there, 31st August 1741.

Heineccius belonged to the school of philosophical jurists. He endeavoured to treat law as a rational science, and not merely as an empirical art whose rules had no deeper source than expediency. Thus he continually refers to first principles, and he develops his legal doctrines as a system of philosophy. His chief works were *Antiquitatum Romanarum Jurisprudentiam illustrantium Syntagma* (1718), *Historia Juris Civilis Romani ac Germanici* (1733), *Elementa Juris Germanici* (1735), *Elementa Juris Naturæ et Gentium* (1737, English trans. by Turnbull, London, 2 vols., 1763). Besides these works he wrote on purely philosophical subjects, and edited the works of several of the classical jurists. His *Opera Omnia* (9 vols., Geneva, 1771, &c.) were edited by his son Johann Christian Gottlieb Heineccius.

HEINECKEN, CHRISTIAN HEINRICH (1721-1725), a child remarkable for extraordinary precocity of intellect, was born on February 6, 1721, at Lübeck, where his father was a painter. Able to speak at the age of ten months, by the time he was one year old he knew by heart the principal incidents in the Pentateuch. At two years of age he had mastered all the sacred history; at three he was intimately acquainted with history and geography, ancient and modern, sacred and profane, besides being able to speak French and Latin; and in his fourth year he devoted himself to the study of religion and church history. This wonderful precocity was no mere feat of memory, for the youthful savant could reason on and discuss the knowledge he had acquired. Crowds of people flocked to Lübeck to see the wonderful child; and in 1724 he was taken to Copenhagen at the desire of the king of Denmark. On his return to Lübeck he began to learn writing, but his sickly constitution gave way, and he died, June 22, 1725.

The Life, Decs, Travels, and Death of the Child of Lübeck were published in the following year by his tutor Schöneich. See also *Teutsche Bibliothek*, vol. xvii., and *Mémoires de Trévoux*, Jan. 1731.

HEINSE, JOHANN JACOB WILHELM (c. 1746-1803), German romance writer, was born at Langenwiesen in the Thuringian Forest, February 16, 1746, or, according to some accounts, February 15, 1749. He was educated at the gymnasium of Schleusingen, and afterwards, through many privations, studied law at Jena and Erfurt. At Erfurt he became known to Wieland, and through Wieland's recommendation to the poet Gleim, who, attracted by some of Heinse's early literary attempts, offered him assistance and a home; but at this time he made the acquaintance of an adventurer, Captain von der Goltz, and was induced to accompany him on his travels. Von der Goltz easily succeeded in corrupting the taste and misdirecting the talents of the young author, and the baneful influence of this friendship pervades Heinse's writings. After parting with Von der Goltz Heinse returned for a time to Langenwiesen, and afterwards obtained, with Gleim's assistance, under the feigned name of Rost, a tutorship in the family of Von Massow at Quedlinburg, which, however, he did not keep very long. In 1774 he went to Düsseldorf to assist J. G. Jacobi in the production of the *Iris* journal. In 1780 he obtained from Jacobi leave and the necessary funds

to travel in Italy. There he remained three years, living chiefly at Rome, where he was intimate with the painter Müller. In 1789 he obtained the post of reader to the elector of Mainz, who afterwards made him councillor and librarian. He died at Aschaffenburg, June 22, 1803.

Heinse's works are—*Singedichte*, Halberstadt, 1771; *Begebenheiten des Enkolp*, translated from the *Satiricon* of Petronius, 2 vols., Schwabach, 1773; *Die Kirschen*, after Dorat's *Cerises*; *Laidion, oder die Eleusinischen Geheimnisse*, Lemgo, 1784; prose translations of Tasso's *Jerusalem Delivered*, 4 vols., 1781, and Ariosto's *Orlando*, 4 vols., 1782; *Ardinghello und die glückseligen Inseln*, 2 vols., Lemgo, 1787; *Hildegard von Hochenthal*, 2 vols., Berlin, 1795; *Anastasia und das Schachspiel*, 2 vols., Frankfort, 1803. A collection of his entire works was published at Leipsic in 1838 in 10 vols., and another edition in 1857 in 5 vols.

HEINSIUS, or HEINS, DANIEL (1580-1655), one of the most famous scholars of the Dutch Renaissance, was born at Ghent, June 9, 1580. The troubles of the Spanish war drove his parents to settle first at Veere in Zealand, then in England, next at Ryswick, and lastly at Flushing. In 1594, being already remarkable for his attainments, he was sent to the university of Franeker to perfect himself in Greek under Henricus Schotanus. He stayed at Franeker half a year, and then settled at Leyden for the remaining sixty years of his life. There he studied under Joseph Scaliger, and there he found Marnix de St Aldegonde, Janus Douza, Paulus Merula, and others, and was soon taken into the society of these celebrated men as their equal. His proficiency in the classic languages won the praise of all the best scholars of Europe, and offers were made to him, but in vain, to accept honourable positions outside Holland. He soon rose in dignity at the university of Leyden. In 1602 he was made professor of Latin, in 1605 professor of Greek, and at the death of Merula in 1607 he succeeded that illustrious scholar as librarian to the university. The remainder of his life is recorded in a list of his productions. He died at the Hague, February 25, 1655. The Dutch poetry of Heinsius is of the school of Roemer Visscher, but attains no very high excellence. It was, however, greatly admired by Martin Opitz, who was the pupil of Heinsius, and who, in translating the poetry of the latter, introduced the German public to the use of the rhyming alexandrine.

He published his original Latin poems in three volumes—*Iambi* (1602), *Elegia* (1603), and *Poemata* (1605); his *Emblemata Anactoria*, poems in Dutch and Latin, were first printed in 1604. In the same year he edited Theocritus, Bion, and Moschus, having edited Hesiod in 1603. In 1609 he printed his Latin *Orations*. In 1610 he edited Horace, and in 1611 Aristotle and Seneca. In 1613 appeared in Dutch his tragedy of *The Massacre of the Innocents*; and in 1614 his treatise *De politica sapientia*. In 1616 he collected his original Dutch poems into a volume. He edited Terence in 1618, Livy in 1620, published his oration *De contemptu mortis* in 1621, and brought out the *Epistles* of Joseph Scaliger in 1627.

HEINSIUS, NIKOLAES (1620-1681), Dutch scholar, was the son of Daniel Heinsius, and scarcely less illustrious than his father. While, however, Daniel was the type of the stationary scholar, Nikolaes was by temperament restless and peripatetic. He was born at Leyden, July 20, 1620, and early displayed an extraordinary precocity. His boyish Latin poem of *Breda Expugnata* was printed in 1637, and attracted much attention. In 1642 he began his wanderings with a visit to England in search of MSS. of the classics; it is unhappily recorded that he met with great discourtesy from the English scholars. In 1644 he was sent to Spa to drink the waters; his health restored, he set out once more in search of codices, passing through Louvain, Brussels, Mechlin, Antwerp, and so back to Leyden, everywhere collating MSS. and taking philological and textual notes. Almost immediately he set out again, and arriving in Paris was welcomed with open arms by the French savants. After investigating all the classical texts he could lay hands on, he proceeded southwards, and visited on the same quest Lyons, Marscilles, Pisa, Florence (where

he paused to issue a new edition of Ovid), and Rome. Next year, 1647, found him in Naples, from which he fled during the reign of Masaniello; he pursued his labours in Leghorn, Bologna, Venice, and Padua, at which latter city he published in 1648 his volume of original Latin verse entitled *Italica*. He proceeded to Milan, and worked for a considerable time in the Ambrosian library; he was preparing to explore Switzerland in the same patient manner, when the news of his father's illness recalled him hurriedly to Leyden. He was soon called away to Stockholm at the invitation of Queen Christina, at whose court he waged war with Salmasius, who accused him of having supplied Milton with facts from the life of that great but irritable scholar. Heinsius paid a flying visit to Leyden in 1650, but immediately returned to Stockholm. In 1651 he once more visited Italy; the remainder of his life was divided between Upsala and Holland. He collected his Latin poems into a volume in 1653. His latest labours were the editing of Velleius Paterculus in 1678, and of Valerius Flaccus in 1680. He died at the Hague, October 7, 1681. Nikolaes Heinsius was one of the purest and most elegant of modern Latinists, and if his scholarship was not quite so perfect as that of his father, he displayed higher gifts as an original writer.

HEINSIUS, NIKOLAES, an illegitimate son of the subject of last article, was born in 1655 at the Hague. At the age of twenty he wrote *The Delightful Adventures and Wonderful Life of Mirander*, a work of extraordinary humour and genius, the sole original romance produced in Holland during the 17th century. Dr Ten Brink has pointed out that *Mirander* preceded *Gil Blas*, which it curiously resembles, by at least forty years. The author, however, added nothing else to literature. He was disowned by his father, driven from the house, and in 1677 had to flee the country on account of a murder which he committed at night in the streets of the Hague. He lived a precarious life as an outlaw in Paris, Rome, and elsewhere, and died in obscurity.

HEIR. See INHERITANCE.

HELDER, or THE HELDEE, a township of the Netherlands at the northern extremity of the province of North Holland, directly opposite the island of Texel. Since 1819 it has been the terminus of the North Holland Canal, and it is now connected (since 1865) by railway with Alkmaar and Haarlem. Its fortifications and its dykes are both constructed on an extensive scale, the former comprising four batteries and five forts, and the latter being the most striking on the whole coast. A garrison of 7000 to 9000 men is necessary for the defence of the place, and 30,000 men could be accommodated within the lines. The harbour, called the Nieuwe Diep, is one of the best in Europe. Its area is 6560 feet long by 330 to 490 broad, and it has depth enough for the largest vessels, which are admitted to the North Holland Canal by the Koopvaarders sluice. The Government arsenal comprises an extensive wet dock, a dry dock, and auxiliary establishments. Besides eight churches and a synagogue Helder possesses a palace for the board of marine, a royal institute for the education of naval cadets, a marine hospital, an orphan asylum, a town-house erected in 1836, and a meteorological observatory. The industries of the place are those usual in a flourishing seaport. Previous to 1819 the population was not much more than 2000, but since then it has rapidly increased. In 1870 the suburbs of Willemseoord, Nieuwe Diep, Nieuwstad, and the Canal Road being included, the total amounted to 16,205. As a commune it numbered 18,366 in 1870 and 20,104 in 1874.

Helder was originally an offshoot of the now decayed town of Huisduinen. The first church was built in 1624, and though the harbour became a favourite resort of the whale fishers, it was not

till the construction of the Nieuwe Diep between 1770 and 1780, and its adoption in 1781 as a war harbour, that the prosperity of the place was secured. Under the Batavian republic the fortifications were extended and strengthened, and Napoleon still further improved them. In 1799 the English, under Abercromby, assisted by the Russians, drove out the French and secured the capitulation of the Dutch fleet in the Zuyder Zee.

HELENA, daughter of Zeus and of Leda the wife of Tyndareus king of Sparta, was sister of Castor, Pollux, and Clytemnestra, and was married to Menelaus. According to Homer she was obliged by Aphrodite to flee with Paris to Troy; and after the Trojan War she returned with Menelaus and lived with him as queen in Sparta. She had only one child, a daughter named Hermione, who was married to Neoptolemus. In the Homeric poems her character is drawn with marvellous skill; forced by the gods to do what she regrets, she seems to be separated from the wrong that she does, and remains always an object of interest and respect.¹ Goethe (*Faust*, part ii.) introduces Helena apparently to symbolize the Greek spirit acting on the modern mind. Among later poets the tales of Helen are much more complicated. She was carried off by Theseus to Attica in her childhood, but was recovered by her brothers. Her character often suffers much in the tales followed by lyric and tragic poets. Stesichorus and Euripides (*Helena*), however, relate that Paris on his homeward voyage was driven by stress of wind to Egypt. Proteus, king of Egypt, learning the facts, detained the real Helen in Egypt, while a shadowy Helen was taken to Troy and fought for. Menelaus on his way home from Troy was also driven to Egypt, and there found his true wife. After the death of Paris she is also said to have been married to his brother Deiphobus.

If we turn to the religious ceremonies and the genuine popular tales, we find traces of a more archaic Helen. At Rhamnus in Attica she was connected with the worship of Nemesis, whose daughter she was considered to be. In Argos she was counted mother of Iphigenia, and was said to have founded a temple of Eileithya, the goddess of birth. At Sparta she was honoured as presiding over the care of children, and festivals were celebrated in her honour by the maidens. A tree appears to have been connected with her worship there (see *Theocr.*, xviii.); and in Rhodes she was worshipped by maidens with the epithet *δενδρίτις*, a relic of the very oldest kind of worship, where a sacred tree was worshipped as the embodiment of the god. In most of these cults connexion with a moon-goddess, the most important of whose functions was the care over child-birth, is apparent; and we are led to regard *ἐλένη* as an epithet of the moon, which has gradually been severed from it and raised to an independent existence (cf. the account given of Gorgophone under GORGON). Beauty is a specially common attribute of the moon and of moon-goddesses, such as Hera. This makes it most probable that the word, like *σαλήνη*, is connected with the root *svar*, to shine. The tales connecting Helena with Achilles, who is clearly a sun-god originally, which are known already to the writer of the *Cypria*, are also very instructive. Over the Black Sea coasts Achilles and Helena were worshipped as united in the Elysian fields. With this we must compare the story of Cadmus and Harmonia (see HARMONIA), and of Hades and Persephone; and we must remember that these colonies of Miletus were closely connected with Attica. We may then look on it as probable that the rape of Helena by Theseus is merely a device of harmonizing skill to connect the Helena of Spartan religion with the Helena worshipped in Attica. Probably a similar reason has contributed to mould the tale which has formed itself round the undoubtedly historical fact of the destruction of Troy by a Greek tribe or army. The worship of Aphrodite, the goddess whose influence in the story of Paris and Helena is so great, was common to Troy and Cythera. Many facts also point to a close connexion between Aphrodite and Helena. The swan from whose egg she is born is the bird of Aphrodite. By the author of the *Cypria* and in Attic tradition Helen is made the daughter of Nemesis; but Nemesis as a goddess of fate is clearly a dawn-goddess (see Kuhn, *Zft.*, iii. 449), and therefore may be identified in origin with Aphrodite. We have here another instance of the intimate relation of the moon and dawn goddesses, and the impossibility of dividing them by any broad line (see HEBE, HERA). It would be at once a most instructive and a most interesting task

¹ Most appreciative and sympathetic analyses may be found in Gladstone's *Homeric Studies* and Murray's *History of Greek Literature*.

to trace the steps by which the antique pre-Greek goddess was gradually transformed into the charming heroine round whom the action of the *Iliad* revolves. The data for reconstructing the history of this figure are more than usually full, and are so clear that writers of the most opposite schools (as Welcker, Gerhard, Mannhardt, Maury, Roscher) have recognized in Helena the ancient goddess.

HELENA, SAINT, a woman of humble origin, said to have been the daughter of an innkeeper, was the wife of Constantine Chlorus. Of her nationality nothing certain is known. She had one son, Constantine the Great. In 292 A.D. Chlorus was raised to the purple by the emperors Diocletian and Maximian, and forced to divorce Helena to make room for a more noble wife. After her son became emperor she was treated with great respect and styled Augusta, and cities in Bithynia and Lysia were after her named Helenopolis. She became a Christian when her son was converted, and during a pilgrimage to Jerusalem she discovered the holy sepulchre and the true cross. Her zealous patronage of their religion made her a favourite with the Christian writers, and finally procured her the honour of canonization; but pagan historians, such as Zosimus, regard her with dislike, and even question, though without ground, the legality of her marriage. Many coins occur with the name of Helena, but it is difficult or impossible in many cases to determine whether they belong to Saint Helena or to others of the family of Constantine bearing the same name.

HELENSBURGH, a town and favourite watering-place of Dumbartonshire, Scotland, is situated at the mouth of the Gareloch, a branch of the Firth of Clyde, opposite Greenock, which is about 4 miles distant. It is 24 miles N.W. of Glasgow by railway. In 1776 the site of the town was advertised for feuing, and in 1802 Helensburgh, named after Lady Helen, wife of Sir James Colquhoun, the superior of the soil, was erected into a burgh of barony, under a provost and council. The boundaries have since been enlarged. The town is pleasantly situated on a gentle slope, the streets mostly intersecting each other at right angles, while many of the houses are surrounded by gardens,—peculiarities that produce an agreeable regularity and openness. A handsome burgh hall was erected in 1879. Near the town is a hospital, and within its boundaries a public park. Convenient as headquarters for visiting the whole district of the Clyde, and connected with Glasgow by both rail and steamer, Helensburgh is much frequented in summer. The population in 1871 was 6231; it is now (1880) estimated at fully 10,000.

HELIAND (*i.e.*, *Heiland*) is an Old Saxon poem of the 9th century. According to some critics it is a fragment of a larger work which dealt with the entire historical material of the Old and New Testaments. The part which we now possess sets forth the life of Christ as told by the four evangelists, whose various narratives the author seeks to harmonize. The poem is said to have been composed by a Saxon writer at the request of the emperor Louis the Pious; but who the author was, except that he was a Saxon, we have no means of knowing. The general opinion is that he lived in Westphalia, but even this is uncertain. Like all the most ancient remains of Teutonic poetry, *Héliand* is written in alliterative verse, of which the writer had a perfect mastery. It is almost the only remnant of the Old Saxon dialect, and has therefore a high philological value, but it is still more interesting from a literary point of view. The poet does not merely repeat his authorities; while true to the main facts of the original story, he allows his imagination to play upon them in a free and poetic spirit. He realized with intense force the incidents in the career of the Founder of Christianity, and gives vitality and definiteness to the received conception of His character. The diction is simple and popular, but marked by an elevation of sentiment adapted to the theme and to its epic treatment; and by a happy phrase the author often succeeds in

imparting to his style colour, variety, and animation. The 9th century is remarkable in the history of Old English and of Old Norse poetry; the *Héliand* affords proof that the impulse which revealed itself in these two literatures was also experienced to the full by the higher minds of Germany. The historical aspects of this great work are hardly less important than those which claim the attention of the purely literary student. Of all the German tribes the Saxons were the last to submit to the influence of Christianity. They regarded baptism as the symbol of Frankish supremacy, and clung as long as they could to the ancient Teutonic faith. Not until Charlemagne, after more than thirty years of warfare, forced upon them Frankish institutions did they generally accept the new creed, and even then, while they talked of Christ and the saints, they thought of Wodan and Thor, and took delight in the heathen poetry which had been handed down from remote periods. Louis the Pious was of a gentle and conciliatory nature, and by treating the Saxons with kindness obliterated to a large extent the recollection of his father's severity. *Héliand* was one of the works with which he and the clergy endeavoured to replace pagan literature, so that we may regard it as the monument of a struggle between two civilizations. The author is dominated by the ideals and the sympathies of the Catholic Church, but occasional touches remind us of the order of life that was passing away, and these have been found suggestive by writers on German archaeology.

Héliand received its name from A. Schmeller, who edited it (Munich, 1830-40) from the two existing manuscripts, one of which is in the British Museum, the other in Munich (formerly in Bamberg). More recent editions have been issued by Köne (Münster, 1855, accompanied by a modern rendering), Heyne (2d ed. Paderborn, 1873), and Rückert (4th volume of *Deutsche Dichtungen des Mittelalters*, Leipzig, 1876). There are renderings into modern German by Kannegiesser (Berlin, 1847), Grein (Rinteln, 1854; improved edition, Cassel, 1869), Rapp (Stuttgart, 1856), and Simrock (2d ed. Elberfeld, 1866). See also Vilmar, *Deutsche Alterthümer im Héliand* (2d ed., Marburg, 1862); Windisch, *Der Héliand und seine Quellen* (Leipzig, 1868); Grein, *Die Quellen des Héliands* (Cassel, 1869); and Sievers *Der Héliand und die angelsächsische Genesis* (Halle, 1875).

HELICON, a mountain, or more strictly a mountain range, of Boeotia in ancient Greece, celebrated in classical literature as the favourite haunt of the muses, is situated between Lake Copais and the Gulf of Corinth. On the fertile eastern slopes stood a temple and grove sacred to the Muses, and adorned with beautiful statues, which, taken by Constantine the Great to beautify his new city, were consumed there by a fire in 404 A.D. Hard by sparkled the famous fountains of poetic inspiration, Aganippe and Hippocrene, the latter fabled to have gushed from the earth at the tread of the winged horse Pegasus, whose favourite browsing place was there. At the neighbouring Ascra dwelt the ancient Hesiod, a fact which probably enhanced the poetic fame of the region. Pausanias, who describes Helicon in his ninth book, asserts that it was the most fertile mountain in Greece, and that neither poisonous plant nor serpent was to be found on it, while many of its herbs possessed a miraculous healing virtue. The highest summit, the present Paleovuni (old hill), rises to the height of about 5000 feet. Modern travellers, aided by ancient remains and inscriptions, and guided by the local descriptions of Pausanias, have succeeded in identifying many of the ancient classical spots. For details of modern research see Clarke's *Travels in Various Countries* (vol. vii, 1818), Dodwell's *Classical and Topographical Tour through Greece* (1818), and Leake's *Travels in Northern Greece* (vol. ii, 1835).

HELIGOLAND (German, *Helgoland*, *Heiligeland*, or *Heilige Land*, as the natives call it, is one of the Frisian Islands, and an English possession, situated in the North

Sea, 54° 11' 34" N. lat., 7° 51' E. long., 36 miles from Cuxhaven at the mouth of the Elbe, and about 100 from Hamburg. Though the red cliffs of the Rock Island are most familiar to the voyager entering the Elbe, there are in reality two islets, the second being the Dune or Sand Island, now lying a quarter of a mile east of the main one, though at one time connected with it by *de waal*, a neck of land which the sea broke through and destroyed in 1720. The Rock Island is nearly triangular in shape, surrounded on every side by steep cliffs, the only beach being the sandy spit where the landing-place is situated, near the south-east point. On this islet there are some 500 houses, divided into a lower town or *Unterland*, on the spit, and an upper town or *Oberland*, situated on the cliff above and connected with the lower town by a wooden stair of 190 steps, the only possible mode of communication between the two sections. The portion of the flat-topped rock not occupied by the houses, the church with graveyard, the Government residences, and place for a battery, comprises a little pastureland, a few cabbage gardens, potato patches, and a powder magazine at the north end of the rock. About 200 sheep, tethered to particular spots, feed on the scanty herbage, eked out by potato-peelings and halms, cabbage blades, or any other vegetable refuse, which is carried out to them every morning. From one end of the island to the other runs a footpath, called by the Heligolanders the "Landwae" or High Road, but better known to visitors by the name of "Kartoffel-Allee" (Potato Walk). There is also a lighthouse; but, though a few guns are placed behind a rude earthwork, there are no fortifications except the inaccessible cliffs of the island, and no garrison of any kind unless a few coast-guardsmen be considered as such. The greatest length of the island, which slopes somewhat from west to east, is 5880 feet, and the greatest breadth 1845 feet, its circumference 13,500 feet, its average height 198 feet, and the highest point 216 feet. The Dune or Sand Island is little more than a sand-bank covered with scanty herbage, and imperfectly bound together by bent, grass, and carices. It is only about 200 feet above the sea at its highest point, but the drifting sands and the constant inroads of the sea make the height rather variable. The sea-bathing establishment is situated here; but, with the exception of the restaurant keeper and waiters, and the attendants who drag the bathing-coaches into the sea, there are no residents. A shelving beach of white sand presents excellent facilities for bathing; everything is under strict Government surveillance, the boats in which the bathers cross in the morning, the hours of bathing, and the tariff being all regulated by law. Approached from the sea the Rock Island, with its red-tiled houses perched in a little cluster on the red cliff,—“Am Falm,” as it is called,—looks very picturesque, and even the narrow brick-paved or sandy lanes of the town are not deficient in a certain degree of quaintness. There are—with the exception of a wheelbarrow and an occasional perambulator—no wheeled carriages in the island, and no horses or other beasts of burden. Even the two cows kept in the *Unterland* for the use of invalid visitors, and whose milk is sold at the apothecary's shop, are removed at the end of the bathing season to Cuxhaven, the island not supplying food for both man and beast. Mud is unknown on the streets, the rain only serving to wash their sloping surfaces clean as the scoured floor of the housewives' kitchens. Most of the houses are built—the lower half at least—of brick, but some are of wood. There are a theatre, a “conversation house,” and a number of hotels and restaurants, though during the season nearly every house is more or less let out to “baadegaster”—visitors for sea-bathing forming the great source of the islanders' prosperity. In both the lower and the upper

town there are numbers of shops; but the articles for sale seem to be chiefly intended for the summer “bathing guests,” the natives getting most of their supplies from Hamburg or Bremen. The dwellings of the fisher-folk are reasonably clean, and the interiors bear evidence of the seafaring character of the population. Some of the houses have little gardens with flowers, cucumbers, &c., in front of them; and in places protected from the sea breezes there are a few fruit trees. At the foot of “the stair” are one or two lime trees sheltered by the contiguous houses; they are looked upon by the Heligolanders as objects of national pride.

During the summer from 2000 to 3000 people visit the island for sea-bathing. Most of these are from Hamburg, English or other “guests” being rare. There are no English residents, the officials, the governor excepted, being either natives or Germans; and German, when Frisian is not employed, is the official language, though for form's sake on the postage stamps English and German words appear in duplicate. The natives speak a dialect of Frisian, barely intelligible to the other islands of the group. They are perfectly content with the almost perfect autonomy they enjoy under the English Government. There is little emigration, and accordingly the population is slowly increasing. In 1879 the number was a little over 2000. There is regular communication with Bremen and Hamburg in the summer and autumn months, but during the winter the island is often isolated for weeks at a time, owing to tempestuous weather, drift ice, and other causes. It is said that insanity and suicide are in consequence not rare. Epidemic diseases occur, though they do not commonly spread; but scrofula, owing to the poor character of the islanders' food, attacks three-fourths of the population. In ten years there were 309 deaths—about 15 to the 1000; while during the same period—from 1863 to 1872 inclusive—there were no less than 17 suicides. At one time the population did not exceed 300, and it was only when it increased to over 1000 that the inhabitants had to dispense with the few horses they kept to till their patches of land. This is now done with the spade, and loads are conveyed either in wheelbarrows or in shallow willow baskets.

The temperature of the *Oberland* is, owing to its exposure, about 1·5° lower than that of the *Unterland*. The following are the means of the months, from a series of observations taken for seven consecutive years at the lighthouse built on the highest point of the island:—January, 31·9° Fahr.; February, 33·9°; March, 35·2°; April, 43·1°; May, 48·9°; June, 57·5°; July, 62·2°; August, 61·0°; September, 58·4°; October, 48·2°; November, 40·0°; December, 31·3°—the mean temperature of the whole year being 47·2° Fahr.¹ The winters are however very stormy, and the air is so laden with salt spray that the rain leaves a delicate deposit of salt after it has evaporated. May and the early part of June are very wet and foggy, so that the first visitors do not arrive until the middle of the latter month.

The rocks composing the island are of Triassic age, bunter-sandstone, keuper, lias, oolite, muschelkalk, and chalk (now denuded), topped by Pliocene—“the brown tock,” in which are found the scales and teeth mostly of freshwater fishes, freshwater *Mollusca*, and fruit and leaves of a *Carpinus*, a *Quercus*, an *Alnus*, a maple, a plant allied to a *hoya* (*Stomatophyllum helgolandicum*), &c. The cliffs are worn into caves, and around the Rock Island are many fantastic arches and columns of rock. There is no just ground, however, for believing that the Rock Island was ever much bigger than it is,—the tales of the great size of Heligoland—its numerous churches and villages in early times—being doubtless exaggerated by tradition, while the maps affecting to show its former extension doubtless relate to the Sand Island, which was incontestably much larger in very recent periods, and is now yearly becoming smaller. The natural history presents nothing remarkable. There are no wild animals on it, and the numerous birds which breed in its cliffs, or light on it during their migrations, all belong to the mainland or to the North Sea.² Hallier has enumerated 220 flowering

¹ Zimmermann, *Die sanitären Zustände Helgoland's, mit specieller Berücksichtigung des Osmogenhaltes der Luft*, 1873, pp. 12, 13.

² Gätke, *Edinburgh New Philosophical Journal*, n. s., ix., p. 333; Blasius, “Naumannia,” 1858, p. 303 (*Ibis*, 1862, p. 58); Corleaux, *Ibis*, 1875, p. 1872.—Mr Gätke, the island secretary, is preparing a special work on Heligoland ornithology.

plants as growing on the island, but none of them are peculiar to it, though there are one or two local varieties. The sandy-bottomed shallow sea supplies abundance of flat fish, and in the deeper water crabs, lobsters, haddock, &c., abound. There are, however, not many fishing-boats, and these of small size. Most of the men act as pilots.

The trade of the island is insignificant. The only time when it enjoyed any commercial prosperity was during the Napoleonic wars, when, by the "Continental system," the European ports were supposed to be shut to England. During that period smuggling prospered, and the island was crowded with soldiers and adventurers. In 1878 the revenue was £7236, the expenditure £7548, and the public debt £2115. The imports are mostly from Bremen and Hamburg, those from Britain being valued at only £72; the exports, consisting chiefly of goods bought by visitors, are ladies' feathers, hats, muffs, fish, &c. The government is vested in a governor appointed by the English crown, aided by a council,—the former mode of government having been more democratic, but less conducive to the islanders' peace than the present. The taxes are few, and consist chiefly of a duty on wine, beer, and spirits, a small house tax, and the "kur-tax," levied on all visitors who reside beyond three days.¹

History.—The history of Heligoland, "the holy island," is interesting. "Sunt et alie insule contra Friesiam et Daniam, sed nulla earum tam memorabilis," writes Adam of Bremen. "Multa regna, multas regiones et insulas perstravi, nec unquam similem huic sacre vidi," are the words of Pontanus. Here Hertha² had her great temple, and hither came from the mainland the Angles to worship at her shrine. Here lived King Radbod, a pagan, and on this isle St Willebrod, 1200 years ago, first preached Christianity; and for its ownership, before and after that date, many sea-rovers have fought. Finally it settled down to be a fief of the dukes of Schleswig or Holstein, though often in pawn for loans advanced to these impunctious princes by the free city of Hamburg. The island thus happened in 1807 to be a Danish possession, when the English seized and held it until it was formally ceded to them in 1814. In these days of swift steamers the value of Heligoland as a military position commanding the Elbe mouth has been doubted. There is not, with the exception of wells, the rain collecting in the "Sapskullen" or hollows, and that caught in casks, any water on the island, while the shelter afforded by the north and south harbours formed by the sand point on which the Unterland is built is but indifferent. It is only vessels of small size that can approach the shore, and passengers by the steamers have to land in open boats at the end of a long jetty (the Låster-Allee, or "Misery Walk"). Under British rule the islanders enjoy the utmost freedom, and in return for this privilege are subjected to a trifling taxation for local purposes, and escape the compulsory military service to which they would be liable were they to become German or Danish subjects.

B.)

HELIODORUS, son of Theodosius, was born at Emesa in Syria, in the second half of the 4th century. He belonged to a family of priests of the Syrian sun-god Elagabalus, but he was himself a Christian, and became bishop of Tricca in Thessaly. He is famous as the author of the best of the Greek love-romances. It is called *Æthiopica*, as it relates the history of Chariclea, daughter of Hydaspes, king of Æthiopia, her love for Theagenes, a Thessalian of high rank, and the happy issue after a series of exciting adventures and hairbreadth escapes. The Alexandrian pastoral poets often introduced brief love episodes to give animation to their scenes of pastoral life. When rhetorical prose became the fashionable style of composition, the mere episode was expanded into a complete history of the lovers from their birth to their happy union. Antonius Diogenes, according to Photius, was the first to write a book of the kind; and Jamblichus, about 100 A.D., also wrote a love

¹ The tax is at present—for one person three marks (Hamburg), for a family of two to three persons four marks, and for larger families six marks; after a stay of four weeks the visitors are free of "kur-tax."

² Fossite, after whom in pre-Christian days the rock was called Fossite-land, was not, as is often asserted, the goddess herself, but only the priestess of Hertha.

romance. But the *Æthiopica* is the oldest work of the kind that has come down to us. It is full of the most improbable scenes and incidents; the hero is a weak and dull character, but the heroine is well drawn and full of interest. The description of customs and manners, especially of religious ceremonies, is minute, and often most interesting in an antiquarian point of view. The work not only became a model for the later Greek romance writers, but has been much imitated by the French and Italian writers of romance. Tasso praises the artful development of the plot; and the early life of Clorinda (*Jerusalem Delivered*, c. xii.) is almost identical with that of Chariclea. Racine meditated a drama on the subject of the romance, and Raphael has made scenes from it the subject of two of his pictures. The best edition is that of Coriès (Paris, 1804). The book has been translated frequently, and into almost all modern European languages.

HELIOGABALUS, a Græcized form of Elagabalus, the name of a Syrian deity, was the name adopted by Varius Avitus Bassianus, the Roman emperor. His pedigree is given in the accompanying table:—

On the murder of Caracalla (217 A.D.), Julia Mæsa was forbidden the court by the new emperor Macrinus. She retired to her ancestral city Emesa with her daughters and grandsons. Varius Avitus, though still only a boy, was appointed high priest of the Syrian sun-god Elagabalus, one of the chief seats of whose worship was Emesa. His beauty, and the splendid ceremonials at which he presided, made him a great favourite with the troops stationed in that part of Syria, and Mæsa increased his popularity by spreading reports that he was in reality the illegitimate son of Caracalla. Macrinus was very unpopular with the army; an insurrection was easily raised, and Varius under his adopted name Helio­gabalus was proclaimed emperor. The troops sent to quell the revolt joined the new emperor, and Macrinus, advancing in person against him, was defeated and soon afterwards slain (218). Helio­gabalus was at once recognized by the senate as emperor. After spending the winter in Nicomedia, he proceeded in 219 to Rome. He made it his business to exalt the honour of the deity whose priest he was. The Syrian god was proclaimed the chief deity in Rome, and all other gods his servants; splendid ceremonies in his honour were celebrated, at which Helio­gabalus danced in public; and it was believed that secret rites accompanied by human sacrifice were performed in his honour. The shameless profligacy of the emperor's life was such as to shock even a Roman public. His popularity with the army declined, and Mæsa perceiving that the liking of the soldiers inclined to Alexander Severus, persuaded him to raise his cousin to the dignity of Cæsar (221). Helio­gabalus soon repented of this step. An attempt to murder Alexander was frustrated by the watchful Mæsa. Another such attempt in 222 produced a mutiny among the soldiers, in which Helio­gabalus and his mother Soæmia were slain.

HELIOGRAPHY is the name applied to the method of communicating between distant points in which visual signals are obtained by reflecting the rays of the sun from a mirror or combination of mirrors in the required direction. This method can of course be only employed to advantage in places where the sky is free from clouds and the atmosphere clear for considerable periods of time, and the fact that an atmospheric change may indefinitely delay the transmission of a message is an insuperable objection to the establishment of permanent heliographic stations in most climates.

in favourable localities, however, heliography possesses important advantages for military signalling over other methods, the principal being the portability of the apparatus, the great distance to which messages can be sent without retransmission, and the fact that the signals are visible to those only who are on the direct line of signalling.

The signals are produced by causing the reflected beam to appear and disappear or be obscured alternately at the distant point, the intervals of appearance and obscuration being usually varied in length, so as to produce the combinations of long and short signals known as the Morse alphabet. This is done in two distinct ways. In the first of these, known as signalling by "appearance," the reflected beam or "flash" is obscured from the receiving station except when a message is being transmitted, the flashes then giving the signals or "dots" and "dashes"; while in the second method, or signalling by "obscuration," the flash is kept continually on the receiving station, and only obscured for intervals forming signals. The first method is more easily read by learners; the second is less fatiguing to the eye, and possesses the advantage of enabling the signaller to correct the adjustment of his instrument at any time.

Glass mirrors with a plane surface are employed, hence the angle of divergence of the extreme rays in the reflected beam is the same as that subtended by the sun's diameter at the point, or about 32 minutes of arc; this small divergence rendering the flash visible to great distances.

The distance through which signalling by this method can be carried on depends on the size of the mirror employed and the angle of reflexion of the rays, a large mirror giving a more intense "flash" than a small one, since it reflects more rays, and being therefore visible to a greater distance; also when the angle of reflexion is nearly a right angle the flash will be more intense than when the rays are only diverted through a small angle from the greater extent of surface exposed to the sun's rays. The range, however, depends to so great a degree on the state of the atmosphere that it is impossible to assign any limits to the distance that the flash might be seen through in exceptionally clear weather. From the Himalayas a 5-inch mirror has been found to give very distinct signals over a distance of 60 miles; but when the air was at all misty a very much larger mirror had to be employed.

The more perfect reflexion when the angle between the direct and reflected rays is large is not sufficient to compensate for the loss of intensity caused by the small number of reflected rays. Hence when this angle is greater than a right angle two mirrors are used, the sun's rays being reflected from one back to the other and thence to the distant point. This is called the duplex method of working.

Two forms of instrument are at present used in the British army. In the one known as Bagbie's field heliostat the mirrors are square, the sun mirror having a side of 5 inches, and the signalling mirror 4 inches. The object of this difference is to ensure the latter receiving the flash over its whole extent of surface. The mirrors are screwed on to tripod stands, the stand for the signalling mirror having a sighting bar with a frame of cross wires at the end, by means of which the alignment can be accurately taken by looking through a hole in the centre of the mirror. When this has been found a small white disc is put into a hole in the centre of the cross wire frame, and a black disc in the central hole in the signalling mirror, or, if two mirrors are used, the white disc in the signalling and the black disc in the sun mirror. The flash is then brought on the true line by making the shadow corresponding to the black disc fall on the white one; this is accurately obtained by means of slow-motion screws in a vertical and horizontal

direction, by which means also the sun's apparent motion is continually corrected. The obscuration is effected by a screen placed on a tripod in the alignment of the flash, pivoted horizontally, and worked by a handle. In the heliograph patented by Mr. Mance the mirrors are circular, the obscuration being effected by giving a small angular motion to one of the mirrors, causing the reflected beam to travel through twice the angle and completely disappear from the distant point. This is more easily manipulated than obscuration by a screen. Its working is made very similar to that of an ordinary Morse key. The sun's motion is corrected by slow-motion screws, and the arrangements for directing the flash are very similar to those in the heliostat. Two tripod stands are employed: one is for the signalling mirror; the other in single working carries a jointed arm, fitted with a small white metal tablet having a black spot on which is thrown the shadow from an unsilvered hole in the centre of the signalling mirror, while in duplex working a piece of paper in the centre of the second mirror answers the same purpose.

In addition to its usefulness as a signalling instrument, the heliograph has been found of great service in defining exactly distant points for large surveys, such as the triangulation of India. For this purpose it was constantly employed by the late astronomer-royal at the Cape, Sir T. Maclear, in his verification of the arc of the meridian. (P. C.)

HELIOPOLIS. See BAALBEC and EGYPT, vol. vii. p. 769.

HELIOOTROPE, or TURNSOLE, *Heliotropium*, L. (Greek, *ἡλιότροπον*, i.e., a plant which follows the sun with its flowers and leaves, or, according to Theophrastus, *Hist. Plant.*, vii. 15, which flowers at the summer solstice), a genus of usually more or less hairy herbs or undershrubs of the tribe *Heliotropiæ* of the natural order *Boraginæ*, having alternate, rarely sub-opposite leaves; small white, lilac, or blue flowers, in terminal or lateral one-sided simple or once or twice forked spikes, with a calyx of five deeply-divided segments, a salver-shaped, hypogynous, 5-lobed corolla, and entire 4-celled ovary; fruit 2- to 4-sulcate or lobed, at length separable into four 1-seeded nuts, or into two hard 2-celled carpels; and seeds generally with a scanty albumen. In some species the cone surmounting the stigma is bearded. The heliotropes are indigenous mostly to tropical and subtropical regions, but a few species are natives of Europe, as *H. europæum*, L., which is also a naturalized species in the southern parts of North America. *H. indicum*, L. (of the section *Helioephyum*, D.C.), is to be met with in equinoctial Africa, America, and Asia, but apparently not in Australis. Of 23 Australian species of *Heliotropium* that have been described, 16 are endemic. The common heliotrope of English hothouses, *H.*

Heliotropium suaveolens.

peruvianum, L., popularly known as "cherry-pie," is on account of the delicious odour of its flowers a great favourite with florists. It was introduced into Europe by the younger Jussieu, who sent seed of it from Peru to the royal garden at Paris. About the year 1757 it was grown in England by Mr P. Miller from seed obtained from St Germain. The plant has been known to occur with double flowers (Masters, *Veg. Terat.*, p. 510, Ray Soc., 1869). *H. corymbosum*, Ruiz et Pav., which was grown in Hammersmith

nurseries as early as 1812, has larger but less fragrant flowers than *H. peruvianum*. The species commonly grown in Russian gardens is *H. suaveolens*, which has white, highly-fragrant flowers. Heliotropes may be propagated either from seed, or, as commonly, by means of cuttings of young growths taken an inch or two in length. The plants require in hot weather a plentiful supply of water, and in winter careful protection from frost, which soon kills them. If favoured with a light rich soil and a warm conservatory, in which they may be grown in a border, or against a pillar, wall, or trellis, they bloom all the year round. The formation of flowers is promoted by a sunny situation. Many florists' varieties of heliotrope are now under cultivation.

Pliny (*Nat. Hist.*, xxii. 29) distinguishes two kinds of "heliotropium," the *triccocum*, and a somewhat taller plant, the *helioscopium*; the former, it has been supposed, is *Croton tinctorium*, L., and the latter the *ἡλιοσκόπιον μικρόν* of Dioscorides, or *Heliotropium europæum*. The helioscopium, according to Pliny, was variously employed in medicine; thus the juice of the leaves with salt served for the removal of warts, whence the term *herba verrucaria* applied to the plant. What, from the perfume of its flowers, is sometimes called winter heliotrope, is the fragrant butterbur, or sweet-scented coltsfoot, *Petasites (Tussilago) fragrans*, Presl., a perennial Composite plant. (For fig. see Maund, *The Botanic Garden*, i., pl. iv., fig. 4, 1878; and *Gardener's Chron.*, Feb. 2, 1878, p. 147.)

See Ruiz and Pavon, *Fl. Peruv.*, ii. 2-4, pl. cvii-cxii, 1799; P. Müller, *Dict.*, ed. T. Martyn, i. pt. ii., 1807; *Hist. Not. de Pinne*, ed. A. de Grandsagne, xiv. 158 seq., 1832; De Candolle, *Prodr.*, x. 532, 1845; Bentham, *Fl. Austral.*, iv. 392, 1869; Bentham and Hooker, *Gen. Plant.*, ii. 843; 1873-76; Hemsley, *Handb. of Hardy Trees and Shrubs*, &c., p. 325, 1873; *Proc. Americ. Acad. Arts and Sci.*, x. 49, Boston, 1875; *Gardener's Chron.*, 1878, p. 21; and, for fig. of *H. peruvianum* and *H. corymbosum*, *Curtis's Bot. Mag.*, No. 141, 1791, and No. 1609, 1814.

HELIOTROPE, or **BLOODSTONE**, a cryptocrystalline variety of quartz, dark green in colour, with small spots of red jasper, resembling drops of blood. The name, from the Greek ἥλιος, sun, and τρέπω, to turn, is stated by Pliny (*Nat. Hist.*, xxxvii. 60) to be due to its giving, when thrown into water, a red reflexion of the light of the sun. The modern heliotrope, however, is Pliny's *prasius* (*op. cit.*, xxxvi. 34); and what he terms heliotrope was apparently a leek-green prase or plasma, abundantly veined with blood-red jasper. Heliotrope is found in the Isle of Rum, and in Mull of Cantyre, Argyllshire, and in several foreign localities. It is of common occurrence in the trap-rocks of the Deccan. Medicinal and other virtues were formerly ascribed to the stone. It is used for signet rings and a variety of ornamental articles.

HELL. See **ESCHATOLOGY**, vol. viii. p. 536.

HELLANICUS, the most important of the Greek logographers, was a native of Mitylene. His father was named Andromenes or Aristomenes. His life, which, as Lucian tells, lasted eighty-five years, extends over the 5th century B.C., but the date of his birth is uncertain, and the circumstances of his career are unknown. If the quotation in the scholiast on Aristoph., *Ran.*, 706, can be trusted (fr. 80), Hellanicus in one of his works referred to the battle of Arginusæ (406 B.C.). In that case (482-397 B.C.) the dates assigned by Müller (*Fragm. Hist. Gr.*, i. p. xxxiv.), following the author of the *Vita Euripidis*, must be approximately correct. On the other hand Thucydides (i. 93), who died in 403 B.C., criticizes the work in which this statement might be expected to occur, which leaves a very narrow interval for the work to appear and acquire reputation enough to be taken notice of by Thucydides; while the style of the reference certainly suggests at first sight that Hellanicus was dead when Thucydides was writing. If on these grounds we disregard the scholiast, we may on the authority of Pámpbila assign 496-411 as the limits of his life. Suidas says that he died at Perperene, a town on the Gulf of Adramyttium, and that he lived for some time at the Macedonian court along with Herodotus. If the latter fact be true, the time to which Suidas assigns it, viz., during the reign of Amyntas (553-504), is impossible.

The following list of his works gives the results of Müller's careful discussion of the extant fragments:—

(1.) *Persica*, probably in two books. This work, which was written before those on Greek history, gave (probably in bk. i.) an account of the Assyrians and the Medes, and (in bk. ii.) a history of the Persian empire. (2.) *Phoronis*, Argolic traditions from Phoroneus, "father of mortal men," the contemporary of Ogyges, down probably to the return of the Heraclidae. It consisted chiefly of genealogies, with short notices of events interspersed. It was probably in two books; and the works quoted as *Bœotica* and *Argolica* are probably only portions of it. (3.) *Deucalionia*, tracing Thesalian traditions in a similar manner from Deucalion, who corresponds to Phoroneus as the first man. It was in two books; and the *Thessalica* is probably only another name for it or the title of a part of it. *Ascpis* was apparently an appendix giving the genealogy of the Æacid race from Zeus and Ægina, daughter of Asopus, down to Miltiades. (4.) *Atlantis*, in two books, briefly enumerating the descendants of Atlas in general, but dwelling at much greater length on the offspring of Electra, and introducing in this part an account of Trojan history. Hence the work is often cited under the name of *Troica*. The works quoted as *περὶ Ἀρκαδίας* and *περὶ Λυδίας* are probably merely parts. (5.) *Althis*, called by Thucydides (i. 97) ἡ Ἀττικὴ συγγραφή, giving in four books the history of the country from Ogyges or Cecrops down at least to the beginning of the Peloponnesian War. Thucydides says that he enumerated the events between 480 and 431 B.C. very briefly, and with little regard to chronological sequence. These four works on Greek history (2-5) were probably published in one single work, and were divided by later grammarians into separate sections and books. (6.) *Lesbiaca* or *Æolica*, a σύνταγμα ἐπιγράφων in two books at least. (7.) *Ἱερείαι τῆς Ἡρας*, a list of the priestesses of the Argive Hera, incorporating a synopsis both of what had been scattered through his other works and of history that had not come within the scope of these works. We may presume that a list of priestesses was preserved in the temple with a slight account of contemporary events, particularly those relating to festivals and religious matters, and that Hellanicus made this the basis of his work. Reference to this line of priestesses was one of the commonest methods of dating, and is used by Thucydides in important cases (ii. 2; iv. 133). This is probably the same work that is often referred to under the name of *Historics*. It was in three books; the first came down to the apotheosis of Heracles and the voyage of Theseus to Crete, and the second probably to the Persian Wars. (8.) *Carnœnice*, a list of the victors in the Carnæan games of Apollo from their foundation, Ol. 26; along with the conquerors in the poetical and musical contests, it probably contained notices of literary events. (9.) *Βαρβαρικά νόμιμα*, quoted also with the titles *περὶ ἔθνων*, &c. As the history of the barbarian races was too little known to be arranged as Hellanicus had arranged the Greek history, the plan in this work was to enumerate the towns, and to describe the country, manners of the people, &c., like a geographer. The *Ægyptiaca* and the *Iter ad Tœnium Ammonis*, which were parts of this work, are counted by Müller spurious insertions on Orphic theology by an Egyptian writer; while *Διὸς πολυτυχία* is merely a part of this spurious insertion. Preller (*De Hellan. Lesb. Histor.*) considers this whole work to be spurious.

As an historian Hellanicus is greatly in advance of preceding logographers. He was not content to repeat the traditions that had gained general acceptance through the poets, but he tried to give the traditions as they were locally current, and he availed himself of the few national or priestly registers that presented something like contemporary registration. Thus, in the first place, he gave in many points accounts quite different from the usual beliefs: e.g., he recorded the local belief in the Troad that Troy had not been totally destroyed by the Greeks but had continued to exist to his own time; and in the *Althis*, touching on Spartan affairs, he made no reference to Lycurgus, but attributed the Spartan constitution to Eurysthenes and Procles. Now it is certain that the Spartan state registers could not have made any mention of Lycurgus on account of the plan on which they were framed (Müller, *Hist. Dor.*, i. p. 132). Secondly, Hellanicus laid the foundations of a scientific chronology, though his materials were insufficient and he often had recourse to the usual rough reckoning by generations. On account of his deviations from common tradition, Hellanicus is often called an untrustworthy writer by the ancients themselves; but probably few authors would have been more useful to a scientific student if his works had been preserved. Dionysius (*Judic. de Thucyd.*) censures him for arranging his history, not according to the natural connexion of events, but according to the locality or the nation he was describing; and undoubtedly he never, like his contemporary Herodotus, rose to the conception of a single current of events wider than the local distinction of race. His style, like that of the older logographers, was dry and bald; and there seems little foundation for the statement of Suidas that he wrote poetry, though perhaps some parts of the *Æolica* were in verse.

HELLEBORE (Greek, ἑλλέβορος; Modern Greek also σκάρφη; German, *Nieswurz*, *Christwurz*; French, *ellebore*, and, in the district of Aranche, *herbe enragée*), *Helleborus*, L., a genus of plants of the natural order *Ranunculaceae*,¹ natives of Europe, Western Asia, and North America. The leaves² are palmate or pedate (BOTANY, vol. iv. p. 111., fig. 108), are usually solitary, and have five persistent petaloid sepals, within the circle of which are placed the minute gland-like tubular petals, the nectaries of Linnæus, of the form of a horn with an irregular opening, and representing, according to Baillon (*Nat. Hist. of Plants*, i. 13, 1871), "the lower or outermost stamens transformed into staminodes."³ The stamens are very numerous, and are spirally arranged; and the carpels are variable in number, sessile or stipitate, and slightly united at the base, and dehisce by ventral suture (vol. iv. 141, 149).

Helleborus niger, L., Black Hellebore, or, as from blooming in mid-winter it is termed, the Christmas Rose (Ger., *Schwarze Nieswurz*; Fr., *Rose de Noël*), is found in southern and central Europe, and with other species was cultivated in the time of Gerard (see *Herball*, p. 977, ed. Johnson, 1733) in English gardens. Its knotty bracteated rhizome is blackish-brown externally, and, as with other species, gives origin to numerous straight roots. The leaves are radical, coriaceous, smooth, distinctly pedate, dark green above, and lighter below, with 7 to 9 segments, and long petioles. The scapes, which end the branches of the rhizome, have a loose entire bract at the base, and terminate in a single flower, with two bracts,

Helleborus niger. 1, Vertical section of flowers; 2, nectary, side and front view (nat. size).

from the axis of one of which a second flower may be developed. The flowers have 5 white or pale-rose, eventually greenish sepals, 15 to 18 lines in breadth; 8 to 13 tubular green petals containing a sweet liquid secretion; and 5 to 10 free carpels.

Varieties of Black Hellebore are *H. niger minor*, or *H. angustifolius*, and Giant Hellebore, distinguished as *H. niger major*, *maximus*, *giganteus*, and *grandiflorus*, or as a distinct species, *H. altifolius*. *H. fatidus*, L., Stinking Hellebore, in Westmoreland Felon-grass, known also, from the shape of its leaves, as Bear's-foot (Fr., *Pied de Griffon*), is a native of England, where, like *H. viridis*, it is confined chiefly to limestone districts; it is common in France and the south of Europe. Its leaves have 7- to 11-toothed divisions, and the flowers are in panicles, numerous, cup-shaped, and drooping, with many bracts, and green sepals tinged with purple, alternating with the five petals.

¹ On the plants known as White Hellebore (*Veratrum album*) and American White Hellebore, commonly called "Green Hellebore" (*V. viride*), which are members of the natural order *Melanthaceae*, see VERATRUM.

² On the development and structural relations of the leaves, see A. Trécul, *Ann. Sci. Nat., Bot.*, ser. iii., tom. xx. 260, 268, pl. 23, figs. 101-3, 1853; and Clos, *Bull. Soc. Bot. de France*, iii. 682, 1856.

³ On the petals of the hellebores, see J. B. Payer, *Traité d'Organogénie comparée de la Fleur*, pp. 256-260, 1857. In the opinion of Baillon (*op. cit.*, pp. 15-21), the groups *Eranthis* and *Coptis*, from the structure of their flowers, as also strictly *Eranthis* and *Trollius*, should not be generically separated from *Helleborus*.

H. viridis, L., or Green Hellebore proper, ranges from England, where it is probably indigenous in some of the southern and eastern counties, to Spain and Italy, and even it is said to Turkey. It has bright yellowish-green flowers, 2 to 4 on a stem, with large leaf-like bracts. Brunfels and Boeck (16th century) regarded the plant as the Black Hellebore of the Greeks.

The radical leaves of *H. viridis* and its varieties, as also of *H. multifidus*, Visian, *H. purpurascens*, W. & K., *H. cyclophyllus*, Boiss., and several allied forms, wither in winter. In *H. vesicarius*, Auch. (Boissier, *Fl. Orient.*, i. 60), a native of Syria, the flower-stem bears 4 to 5 flowers, and the carpels are much compressed laterally, and, when ripe, united half way up, as in certain *Nigellæ*. *H. lividus*, Soland (*H. argutifolius*, Viv., *trifolius*, Mill., and *vicifolius* and *triphylus*), Holly-leaved Hellebore, found in the Balearic Islands, and in Corsica and Sardinia, is remarkable for the handsomeness of its foliage. *H. antiquorum*, Braun, which has purplish-white flowers, occurs in Bithynian Olympus. *H. olympicus*, Lindl., is perhaps a variety of it. *H. cyclophyllus* (Boiss., *Fl. Orient.*, i. 61), a Grecian species, has ovate-orbicular green sepals. *H. orientalis*, Lam., *Ency.*, iii. 92 (*H. ponticus*, Braun, see Boiss., *op. cit.*), indigenous to Macedonia, Thrace, the vicinity of Constantinople, and northern Asia Minor as far east as Trebizond, has leaves pubescent below, and of 7 to 9 segments, and scapes bearing 3 to 5 flowers, with white or rosy sepals. Allied to it are *H. odoratus*, W. & K., of which Koch regards *H. atrorubens* as a variety, and *H. caucasicus*, Koch,⁴ having green and purplish-green sepals respectively.

Hellebores may be grown in any ordinary light garden mould, but thrive best in a soil of about equal parts of turfy loam and well-rotted manure, with half a part each of fibrous peat and coarse sand, and in moist but thoroughly-drained situations, more especially where, as at the margins of shrubberies, the plants can receive partial shade in summer. For propagation, cuttings of the rhizome may be taken in August, and placed in pans of light soil, with a bottom heat of 60° to 70° Fahr.; hellebores can also be grown from seed, which must be sown as soon as ripe, since it quickly loses its vitality. The seedlings usually blossom in their third year. The exclusion of frost favours the production of flowers; but the plants, if forced, must be gradually inured to a warm atmosphere, and a free supply of air must be afforded, without which they are apt to become much affected by greenfly. The flowers on one plant of *H. niger major* in Mr B. Hooke's garden at Bradfield, Berks, about the end of January 1878, numbered nearly 500 (*Gard. Chron.*, 1878, i. 145). For potting, *H. niger* and its varieties, and *H. orientalis*, *atrorubens*, and *olympicus* have been found well suited. After lifting, preferably in September, the plants should receive plenty of light, with abundance of water, and once a week liquid manure, not over-strong. The flowers are improved in delicacy of hue, and are brought well up among the leaves, by preventing access of light except to the upper part of the plants. Of the numerous species of hellebore now grown, the deep-purple-flowered *H. colchicus* is one of the handsest. *H. atropurpureus*, introduced in 1844, blooms in March or at the end of February, and may be effectively used in flower borders to succeed hepaticas, scillas, and crocuses (Maund, *Bot. Gard.*, vi., pl. ccxviii., fig. 2). Hellebores having variously coloured spreading or bell-shaped flowers, spotted with crimson, red, or purple, were grown by Sauer, late superintendent of the Berlin University Garden, about the year 1851, as the result of crossing *H. guttatus*, Braun, and *H. purpurascens*. Other fine varieties have been obtained by Bouché, his successor, from crosses with *H. olympicus*, and by Carl Heinemann from *H. guttatus* and *H. abchasicus*.

The rhizome of *H. niger* occurs in commerce in irregular and nodular pieces, from about 1 to 3 inches in length,

⁴ According to Regel, *H. orientalis*, *caucasicus*, *colchicus*, *antiquorum*, *olympicus*, *guttatus*, and *abchasicus* should all be reduced to one species. Koch (*Gard. Chron.*, 1874, i. 118) regards the Hungarian *H. purpurascens*, W. & K., and the Caucasian *H. colchicus*, Reg. (= *H. porphyromelas*, Brana), as varieties of the last-named. The "*H. abchasicus*" of Belgian florists is stated by M. J. L. Le Bîle ("Monog. des Helléb.," *La Belgique Horticole*, vii. 331) to be merely a variety of *H. intermedium*, Guss.

white, and of a horny texture within. Cut transversely it presents internally a circle of 8 to 12 cuneiform ligneous bundles, surrounded by a thick bark. It emits a faint odour when cut or broken, and has a bitter and slightly acrid taste. The drug is sometimes adulterated with the rhizome of baneberry, *Actæa spicata*, L., which, however, may be recognized by the distinctly cruciate appearance of the medullium of the attached roots when cut across, and by its decoction giving the chemical reactions for tannin.¹ The rhizome is darker in colour in proportion to its degree of dryness, age, and richness in oil. A specimen dried by Schroff lost in eleven days 65 per cent. of water.

H. niger, *orientalis*, *viridis*, *fatidus*, and several other species of hellebore contain the glucosides *helleborin*, $C_{36}H_{42}O_6$, and *helleborcin*, $C_{35}H_{41}O_5$, the former yielding glucose and *helleboresin*, $C_{30}H_{38}O_4$, and the latter glucose and a violet-coloured substance *helleboretin*, $C_{14}H_{20}O_3$. Helleborin is most abundant in *H. viridis*. A third and volatile principle is probably present in *H. fatidus*. Both helleborin and helleboretin act poisonously on animals, but their decomposition-products helleboresin and helleboretin seem to be devoid of any injurious qualities. Helleborein produces excitement and restlessness, followed by paralysis of the lower extremities or whole body, quickened respiration, swelling and injection of the mucous membranes, dilatation of the pupil, and, as with helleborein, salivation, vomiting, and diarrhoea. Helleborein exercises on the heart an action similar to that of digitalis, but more powerful, accompanied by at first quickened and then slow and laboured respiration; it irritates the conjunctiva, and acts as a sternutatory, but less violently than veratrine.

Of various species of hellebore examined by him, Schroff found *H. orientalis* to possess most medicinal activity; less energetic in succession were *H. viridis*, *fatidus*, *purpurascens*, *ponticus* (? Braun, *v. sup.*), and *niger*. Pliny states that horses, oxen, and awine are killed by eating "black hellebore;" and Christison (*On Poisons*, p. 876, 11th ed., 1845) writes: "I have known severe griping produced by merely tasting the fresh root in January." Parkinson, who questions the virulence of the drug (*Theat. Botan.*, p. 216, 1640, fol.), possibly observed its effects in the dry condition. According to Bergius (*Mat. Med.*, ii. 496, Stockh., 1778), the rhizome of *H. niger*, if fresh, is poisonous, rubefacient, and vesicant; when recently dried, emetic, purgative, emmenagogue, insecticidal, and sternutatory; and after long keeping scarcely purgative, but alterative and diuretic. Rayer also has observed that when dried and powdered it is almost devoid of purgative properties. Poisonous doses of hellebore occasion in man singing in the ears, vertigo, stupor, thirst, with a feeling of suffocation, swelling of the tongue and fauces, emesis and catharsis, slowing of the pulse, and finally collapse and death from cardiac paralysis. Inspection after death reveals much inflammation of the stomach and intestines, more especially the rectum. The drug has been observed to exercise a cumulative action. Its extract was an ingredient in Bacher's pills, an empirical remedy once in great repute in France. In British medicine the rhizome was formerly official (see J. B. Nevins, *Transl. New Lond. Pharm.*, p. 666, 2d ed., 1854), and the tincture, powder, or, more rarely, the decoction is still occasionally used. Parkinson (*op. cit.*) mentions the employment of the leaves and juice of *H. niger* "to help the Dropsie, Jaundies, and other evil dispositions of the liver and gall;" and Dr C. D. F. Phillips (*Mat. Med. and Therap.*, p. 27, 1874) has found the tincture of the rhizome of value in dropsical affections, especially in anasarca resulting from scarlet fever. *H. fatidus* was in past times much extolled as an anthelmintic, and is recommended by Bisset (*Med. Ess.*, pp. 169 and 195, 1766) as the best vermifuge for children; J. Cook, however, remarks of it (*Oxford Mag.*, March 1769, p. 99): "Where it killed not the patient, it would certainly kill the worms; but the worst of it is, it will sometimes kill both." This plant, of old termed by farriers Ox-heal, Setter-wort, and Setter-grass, as well as *H. viridis* (Fr., *Herbe à ston*), is employed in veterinary surgery, to which also the use of *H. niger* is now chiefly confined in Britain.

In the early days of medicine two kinds of hellebore were recognized, the white, or *Veratrum album* (*vide supra*, note), and the black, including the various species of *Helleborus*. The former, according to Codronchius (*Comm. . . . de Elleb.*, 1610), Castellus (*De Helleb. Epist.*, 1622), and others, is the drug usually signified in the writings of Hippocrates. Among the hellebores indigenous to Greece and Asia Minor, *H. orientalis*, Lam. (*v. supra*), the rhizome of which differs from that of *H. niger* and of *H. viridis* in the bark being readily separable from the woody axis, is the species found by Schroff to answer best to the descriptions given by the ancients of black hellebore, the *ἑλλέβορος μέλας* of Dioscorides. The rhizome

of this plant, if identical, as would appear, with that obtained by Tournefort at Prusa in Asia Minor (*Rel. d'un Voy. du Levant*, ii. 189, 1718), must be a remedy of no small toxic properties. According to an early tradition, black hellebore administered by the soothsayer and physician Melampus (whence its name *Melampodium*), was the means of curing the madness of the daughters of Proetus, king of Argos. The drug was used by the ancients in paralysis, gout, and other diseases, more particularly in insanity, a fact frequently alluded to by classical writers, e.g., Horace (*Sat.*, ii. 3, 80-83; *Ep. ad Pis.*, 300). Various superstitions were in olden times connected with the cutting of black hellebore. The best is said by Pliny (*Nat. Hist.*, xxv. 21) to grow on Mt. Helicon. Of the three Anticyras (see vol. ii. p. 127), that in Phocis was the most famed for its hellebore, which, being there used combined with "sesamoides," was, according to Pliny, taken with more safety than elsewhere.

HELLENISTS (Ἑλληνοισταί) was the name usually applied by those who called themselves Greeks (Hellenes) to all Græcizing and more especially to all Greek-speaking foreigners,—a class which, after the conquests of Alexander the Great, formed a large and important element in almost every community throughout the civilized world. More particularly the word is applied in the New Testament (Acts vi. 1; ix. 29; and, according to the *textus receptus*, also xi. 20, where, however, the best MSS. and critical editions read Ἑλληνας) to Greek-speaking or "Grecian" Jews, who, besides being very numerous in the various countries of the dispersion, had also many synagogues in Jerusalem, and were remarkable there for their zeal. Indeed their presence in the capital of Judaism at all may safely be taken to have implied on their part a more than ordinary interest in the affairs of the ideal theocratic kingdom; their attitude therefore to Christianity, when that new system first came to be promulgated, could not fail to be very pronounced on the one side or on the other. The early records show that the apostles made many converts among the Hellenists of the city; and it is interesting to note that, if the names can be taken as a safe indication, all the seven deacons mentioned in Acts vi. 5 belonged to the "Hellenistic" and not to the "Hebrew" party within the primitive church. Saul of Tarsus also was a Hellenist; but whether he belonged to the synagogue of the "Libertines" or to that of "those of Cilicia" is a question which our data do not enable us to decide. In the Vulgate, which translates Ἑλληνοισταί by the word "Græci," the distinction so consistently preserved in our authorized version between "Grecians" and "Greeks" is made to disappear.

HELLESPONT, the modern DARDANELLES (vol. vi. p. 823), is variously named in classical literature Ἑλλησποντος, Hellespontus, ὁ Ἑλλης πόντος, Pontus Helles, Hellespontum Pelagus, and Fretum Hellesponticum. It received its name from Helle, in Greek mythology, daughter of Athamas, king of Orchomenus in Bœotia, and of the goddess Nephele, whom he had married at the command of Hera (Juno). Athamas, however, secretly loved the mortal Ino, and on his marrying her also the dissensions between his wives became so great that he went to consult the Delphic oracle. The priestess there, bribed by Ino, assured him that the sacrifice of Phrixus, the brother of Helle, was necessary to domestic harmony; but Nephele, in order to save her children, despatched them to Colchis in Asia, on the back of the ram with the golden fleece. Helle, however, had the misfortune, when crossing this strait, to

¹ For the microscopical characters and for figures of transverse sections of the rhizome, see Lanessan, *Hist. des Drogues*, i. p. 6, 1878.

slip from her seat, and to be carried away by the current : hence the name *Hellespontus*, or "Sea of Helle."

HELLIN (*Illunum*), a town of Spain, in the province of Albacete, is situated on the slope of the Sierra de Segura, 35 miles S.S.E. of Albacete. It is a clean and well-built town, and possesses the remains of an old Roman castle and a beautiful parish church, the masonry and marble pavement at the entrance of which are worthy of special notice. The principal manufactures are sulphur obtained from the celebrated mines about 13 miles distant, earthenware, linens, cloth, hats, leather, and oil. Hellin was sacked by the French under Montbrun; and was the point where Joseph and Soult united with Suchet after Marmont's rout at Salamanca. The population is about 8000.

HELMERS, JAN FREDERIK (1767–1813), Dutch poet, was born at Amsterdam, March 7, 1767. His early poems *Night* (1788) and *Socrates* (1790) were tame and sentimental, but he woke up after 1805 to the melancholy condition of the Fatherland, and determined, in company with his friend Cornelis Loots, to rouse national feeling by a burst of patriotic poetry. His poems, published in 1809 and 1810, but especially his great work *The Dutch Nation* (1812), created great enthusiasm and enjoyed immense success. Helmers died at Amsterdam, February 26, 1813. He was a fiery, somewhat turgid writer, by no means devoid of force, but owing his success mainly to the integrity of his patriotism and the opportune moment at which he sounded his counterblast to the French oppression. His posthumous poems were collected in 1815.

HELMET, or HELM (Anglo-Saxon, *Helm*; Italian, *Elme*, *Elmetto*; French, *Heaume*; Icelandic, *Hjalnr*), is the term used in a general sense to include the various forms of head defences which were either made in solid metal or of metal plates. The form of helmet used among the Assyrians, as shown by the monumental sculptures, was a close-fitting skull-cap, round or conical, sometimes surmounted by a crest rising from the summit of the cone and curving forwards in a semicircular form. The Greek helmet was also in its simplest form a skull-cap, covering the head in front above the level of the eyes, but reaching down to the nape of the neck from ear to ear. Another form had this lower part prolonged and carried round so as to cover all above the shoulders with the exception of a slit in front, partly protected by a nose-piece. Occasionally hinged cheek-pieces were added to the skull-cap, and the upper part of the casque was sometimes prolonged into a conical shape with a crest curving forwards, or surmounted by a ridged prominence on which was fastened a flowing crest of horsehair. The Greek helmets are often represented as highly decorated, and many examples of the different forms and their varieties of decoration occur on the painted vases, the gems, and the coinage. The Etruscan helmet differed but slightly from that of the Greeks. It was more conical in form, and often furnished with horns or wings in place of a crest. The Roman helmet was usually a skull-cap, with or without crest, and often plain and undecorated. The Gaulish helmet, of which a beautiful specimen was obtained from an Iron Age burial at Berru in Marne in 1872, was of hammered iron, conical in shape, terminating in an ornamental apex, and having a richly decorated border round the lower part. Conical helmets of an earlier character found at Theil and Auxonne have been assigned to the Age of Bronze. A silver helmet of the Early Iron Age, consisting of a skull-cap with a mask for the face fastened together by a hinge, which was found in the Thorsbjerg Moss in South Jutland, is the only specimen known of the early Teutonic helmet. An Anglo-Saxon helmet of iron, shaped like a skull-cap, and formed of ribs or flat strips of metal, covered with plates of horn, and surmounted with the figure of a boar, was found in a tumulus

at Benty Grange in Derbyshire. Such boar-crowned helmets are referred to in the Anglo-Saxon poem of Beowulf. The helmets worn by the Normans and Saxons at the time of the Conquest, as shown in the Bayeux tapestry, were conical in shape with a projecting nasal. The earliest known example of a date subsequent to the Norman Conquest is one which was discovered in the church of Faversham, and is now in the Musée d'Artillerie at Paris. It preserves the conical top of the earlier Norman headpiece, but has a barrel-shaped body, covering all the head and face with the exception of a vertical slit partially protected by a projecting nasal, and having transverse apertures on either side for the eyes. This barrel-shape, with flattened instead of conical top, continued in use during the 12th century in England, although the conical cap with the nasal appears on the great seals of the Scottish kings down to the time of Alexander II. The helm of Edward the Black Prince (died 1370), which still hangs over his tomb in Canterbury Cathedral, has the top shaped like a truncated cone and the lower part more oval than barrel-shaped, the aperture for sight taking the form of a transverse slit between the upper and lower parts of the helm. In the lower portion the perforations for breathing are arranged in the form of a crown on both sides. The helm of Henry V. (died 1422), which hangs with his saddle and shield above his tomb in Westminster Abbey, is lower in the crown, more rounded to the shape of the head, and the *ocularium* or perforation for sight is protected by the projection of the lower part beyond the line of the upper. The helm of King Henry VI, which was suspended over his tomb in St George's Chapel, Windsor, has the lower part contracted to the form of the neck and rounded to the shape of the shoulders. The *ocularium*, which is wide, is protected by a series of curved bars riveted across it. The helm of Edward IV. (died 1483), which was also suspended in St George's Chapel, exhibits a still greater shaping to the form of the neck and shoulders; the top is rounder, and has a spike for a crest. In the end of the 15th century the great helm was superseded by the smaller headpiece with movable vizor and beaver or chinpiece and neck guard, which is properly styled a helmet. Other varieties of headpiece were the bascinet, of a plain oval form pointed at the top and somewhat compressed on the sides, having holes at the bottom for the attachment of the camail or gorget of chain-mail. The bascinet was sometimes worn alone and sometimes under the helm. It was succeeded in the 15th century by the salade, a lighter skull-cap with the hinder part projecting, and occasionally a movable vizor. The armet, the burgonet, and the casque are varieties of the lighter form of headpiece, partaking more or less of the skull-cap form, while the morion and the chapelle de fer were distinguished by their flattened brims.

HELMOND, a town of the Netherlands, in the province of North Brabant, to the left of the river Aa, with a station (since 1866) on the state railway between Venloo and Eindhoven. The castle of Helmond remains a beautiful specimen of the architecture of the 15th century, and among the other buildings of note in the town are the spacious church of St Lambert, the Reformed church, and the town-house. Cotton-weaving on a very extensive scale, dyeing, iron-founding, brewing, soap-boiling, and tobacco dressing are the chief industries of the commune. The population of the town proper in 1870 was only 5280, but the commune, which includes several suburbs, had about 6500.

Helmond is first mentioned as a town in 1354, but it may possibly be identical with a certain Harlemont or Harlout which appears in the 12th century. In the middle of the 13th century it was the favourite residence of Mary of Brabant, queen of the Romans. Fortified shortly after the attack of the people of Guelderland in 1543, it continued a place of military importance till the

peace of Münster. The occupation of the town by the duke of Parma in 1579, its recovery by the states of Holland in 1581, its capture by the count of Hohenlohe in 1588, and the seizure of the castle by Count Frederick of Nassau are the chief events in its military annals. In 1814 the town received the right of parliamentary representation, but it afterwards lost the privilege.

HELMONT, JEAN BAPTISTE VAN (1577-1644), was born at Brussels in 1577. He was educated at Louvain, and began the study of natural science under the Jesuits in that city. Their hard and dry philosophy, however, had few attractions for a nature so ardent and imaginative as his. Turning for relief to other systems, he found no rest except in the mysticism of A Kempis and Tauler. From them he learned that wisdom is the gift of the Supreme Being, that it must be obtained by prayer, and that we must renounce our own will if we wish to participate in the influence of the divine grace. From this time he began a life of exemplary meekness and humility, made over his property to his sister, and retired from the high society in which he had hitherto walked. He devoted himself to the study of medicine, read carefully all that had been written on the science, and felt dissatisfied with its method and results. He then turned to Paracelsus and the alchemists, and conferred a real boon on humanity by rescuing chemical science from the erratic absurdities of the post-Paracelsian alchemists, and applying to it more philosophical principles. He graduated as M.D. in 1599, and, after travelling through France and Italy, Switzerland and England, married a rich lady of Brabant, by whom he had several children. He died in Holland in 1644, in the sixty-seventh year of his age. Science is under real obligations to Van Helmont, though the greater part of his speculations present a curious mixture of mystical philosophy and acute chemical research. To him is due the invention, or at least the first application, of the term "gas" in the sense in which it is now used. He also discovered that gas was disengaged in abundance by the application of heat to various bodies, and during the solution of various carbonates and metals in acids.

Van Helmont's works were published at Amsterdam in 1648 by his son Mercurius; a more accurate and complete edition is that of Elzevir, 1652. The fullest account of his speculations is given in Rixner and Steber, *Beiträge zur Geschichte der Physiologie* (1819-26), Hft. vii. See, also Spiess, *Helmont's System der Medicin*, 1840; Rommelaere, *Études sur J. B. v. Helmont*, 1863. Van Helmont's mystical theosophy and alchemy appeared in even greater confusion in the works of his youngest son, Franz Mercurius, who was born in 1618 and died, after a somewhat adventurous and troubled life, at Berlin in 1699. His chief works are *Cabbalah Denudata*, 1677; *Paradoxal Discourses*, 1685; and *Opuscula Philosophica*, 1690.

HELMSTÄDT, or HELMSTEDT, a town of Germany in the duchy of Brunswick, is situated on the railway from Magdeburg to Brunswick, 23 miles E. of Brunswick. It is the seat of a circle directorate, and of a circle and a district court. The principal buildings are the Juleum in the Byzantine style, founded by Duke Julius of Brunswick in 1575 for the university which was abolished in 1809, and now containing an old library of 40,000 volumes; the church of St Stephen's, dating from the 12th century; the Lutheran female institution, with a beautiful church in the Roman style; and the Catholic church and ruined monastery of St Ludger. The educational institutions include a gymnasium, two city schools, an agricultural school, and two female schools of the higher grade. The principal manufactures are yarn, soap, tobacco, sugar, vitriol, earthenware, and tobacco pipes. Not far from the town there is an iron mineral spring especially efficacious in gouty affections. Near it a monument has been erected to those who fell in the Franco-German war of 1870-71; and in the town there is also a monument to those who fell at Waterloo. The population in 1875 was 7783.

Helmsstädt originated in connexion with the Ludger monastery, founded by Ludger, the first bishop of Münster, about the end of the 8th century. It obtained town rights in 1099, and although destroyed by the archbishop of Magdeburg in 1199 it was soon

rebuilt. In 1457 it joined the Hansa, and in 1490 it came into the possession of Brunswick. See Kuhlhard, *Beiträge zur Geschichte der Universität Helmstädt*, 1797; Ludewig, *Geschichte und Beschreibung der Stadt Helmstädt*, 1821; *Geschichte der ehemaligen Hochschule Julia Carolina zu Helmstädt*, 1876.

HELOISE. See ABELARD.

HELOTS, in Grecian antiquity, were the serfs or bondsmen of the Spartans. The most probable of the various explanations of their origin seems to be that they were the early aborigines of Laconia, who at the time of the Dorian invasion were reduced to slavery by the conquerors. The name is perhaps best derived from the root *ἐλ*, found in *ἐλεῖν*, *ἔλων*, and other words. The Helots were the lowest class of the inhabitants of Sparta; but those of them who were emancipated formed the class of *Neodamodes*, next in political rights to the Spartan citizens themselves. The *Mothones* or *Mathakes* were domestic slaves who had been brought up along with the young Spartans, and afterwards liberated. The Helots were the property of the state, which alone had the right of emancipating them, although it made over their services to individuals. They were attached to the soil—*ascripti glebæ*—and could not be sold away from it. They tilled the land which was allocated to them in the proportion of one lot to several families; and for each lot they paid to their masters an annual rent of 82 medimni of barley, and a quantity of wine and oil. They were also employed on public works, and performed all domestic service. In time of war the Helots generally served as light-armed troops; but when on special emergencies they fought as *hoplites*, they were usually rewarded with their freedom. The first occurrence of this kind was under Brasidas in 424 B.C. In the fleet the great bulk of the sailors were Helots. Although every care was taken to distinguish the serf from his lord, even in the matter of dress, the accounts of the cruel treatment of the Helots by the Spartans only hold true of the later history of Lacedæmon. The condition of the Helot was better than that of a slave in other Greek states, for, being a serf of the soil, he was not wholly at the mercy of his master, and there was a legal way whereby, after many stages, he could eventually attain freedom and citizenship. After the Messenian war, however, when the multitude of the Helots made them formidable to the diminished numbers of the full citizens, there is no doubt that very cruel measures were adopted against them. The evidence is strong that the *Crypteia*, instituted ostensibly to inure the Spartan youth to hardship, was really intended to reduce the number of the Helots by assassination; and we know from Thucydides (iv. 80) that on one occasion 2000 Helots were treacherously massacred by the Spartan citizens. At the close of the second Messenian war (668 B.C.), the conquered Messenians were classed with and treated as the Helots, till Epaminondas restored them to their native country after the battle of Leuctra (371 B.C.).

For further details see Plutarch's *Life of Lycurgus*, Thirlwall's *History of Greece*, Grote's *History of Greece*, Müller's *History of the Dorians*, and Hermann's *Political Antiquities of Greece*.

HELPS, SIR ARTHUR (1813-1875), fourth and youngest son of Thomas and Ann Frisquett Helps, was born at Balham Hill, in the parish of Streatham and county of Surrey, on the 10th of July 1813. His father was then and for many years afterwards head of a large mercantile house in the city of London, and for the last thirteen years of his life treasurer of St Bartholomew's Hospital. His mother was the only surviving child of John, fourth son of the Rev. Charles Plucknett, M.A., of Wincanton. After the usual preliminary training at Eton, young Helps went to Trinity College, Cambridge, passing as B.A. in 1835, when he came out 31st wrangler in the mathematical tripos, and taking his M.A. degree in 1839. Although he took no high honours at the university,—and indeed he

had not health sufficiently robust, even if he had possessed the ambition, to achieve them,—he was recognized by the ablest of his contemporaries there as a man of superior gifts, and likely to make his mark in after life. They showed this by electing him as a member of the Conversazione Society, better known as the Apostles, a society which had been established in 1820 for the purposes of discussion on social and literary questions by a few young men attracted to each other by a common taste for literature and speculation. A body which in its early days included the names of Charles Buller, Frederick Maurice, Richard Chenevix Trench, Monckton Milnes, Arthur Hallam, and Alfred Tennyson had in it every element to make its gatherings delightful as well as useful. To be elected into its limited circle was a distinction of which Arthur Helps was proud then and to the close of his life; and, familiar as he was with the best and most intellectual society of his time, the social hours passed year by year with the Cambridge Apostles were always counted by him among his happiest, both in anticipation and in remembrance.

In the discussions of these and later days Helps may have found the suggestions for the dialogues of the *Friends in Council*, in which his genius appears at his best. But his first literary effort, which appeared under the title of *Thoughts in the Cloister and the Crowd* in 1835, the year he took his B.A. degree, assumes a very different but scarcely less ambitious form, that of a series of aphorisms upon life, character, politics, and manners. As a rule, such things are only valuable when they come as the fruits of wide experience and matured thought. Still in this volume are to be found passages which may take their place beside the sayings of Vauban, Chamfort, and other masters of aphorism of the second rank, and are quite equal in quality to the many pithy quotable sayings scattered through Helps's later works.

Soon after leaving the university, where he had established many valuable friendships, Arthur Helps became private secretary to Mr Spring Rice (afterwards Lord Monteagle), then chancellor of the exchequer in Lord Melbourne's administration. This appointment he filled till 1840, when he went to Ireland as the private secretary of Lord Morpeth (afterwards earl of Carlisle), then the chief secretary of state for Ireland, where he remained until his principal left Ireland in 1841, on the Government passing from Lord Melbourne into the hands of Sir Robert Peel. In the meanwhile (28th October 1836) Helps had married Miss Bessy Fuller, a young Irish lady. He was also appointed one of the commissioners for the settlement of certain Danish claims which dated so far back as the siege of Copenhagen; but with the fall of the Melbourne administration his official experience closed for a period of nearly twenty years. The character which he had established for himself by his tact, sagacity, and business habits was not, however, forgotten by his political friends. And combined as these qualities were with an admirable manner which invited confidence while it repelled intrusion, and with a reticence and discretion on which absolute reliance could be placed, his fitness for official life was unmistakable. When therefore the clerkship of the Privy Council became vacant in 1860, on the resignation of the Hon. W. L. Bathurst, he was recommended for the appointment by his old friend Lord Granville, who knew that for ability, tact, and discretion it could not be in safer hands.

During his early official career Helps cultivated literature with varying success. His *Essays written in the Intervals of Business*, published in 1841, and his *Claims of Labour, an Essay on the Duties of the Employers to the Employed*, published in 1844, continue to interest, and are likely to keep their place in well-selected libraries. But two plays, *King Henry the Second, an Historical Drama*, and *Catherine*

Douglas, a Tragedy, both published in 1843, have no particular merit. Neither in these, nor in his only other dramatic effort, *Culita the Serv*, published in 1858, a work far superior, however, to his earlier efforts of the same kind, are to be found the sense of dramatic situation and movement, the sharp outlines and contrast of character, or the fitness and concise force of diction which alone justify the selection by an author of the dramatic form as the vehicle for his thoughts. Helps possessed, however, just enough dramatic power to give life and individuality to the dialogues which he introduced with excellent effect to enliven many of his other books. His first effort in this direction was in *Friends in Council, a Series of Readings and Discourse thereon*, published in 1847 and 1851. The plan of this book seems to have been suggested by a passage in Bacon's essay *Of Discourse*, which appears as the motto of it. "It is good in discourse and speech of conversation to vary and intermingle speech of the present occasion with arguments, tales with reasons, asking of questions with telling of opinions, and jest with earnest; for it is a dull thing to tire, and, as we say now, to jade anything too far." The variety and conflict of opinion, the play of character, the flashes of humour, got by submitting the formal essays on social and moral questions which made the staple of these volumes to be criticized and pulled to pieces by the imaginary personages, who, under the names of Milverton, Ellesmere, and Dunsford, grew to be almost as real to Helps's readers as they certainly became to himself, gave a special charm to a book which, by its richness of suggestion, its sweetness of tone, and beauty of style, made for its author a high and enduring reputation. The same expedient was resorted to for the discussion of the ideas of social and philanthropic improvement on which Helps's mind was always at work, in a second series of *Friends in Council*, published in 1859, and again in *Conversations on War and General Culture*, published in 1871. The old familiar speakers, with others added, also appeared in his *Realms*, and finally in what certainly must always rank as the best of its author's later works, *Talk about Animals and their Masters*, published in 1873.

The subject of slavery was one which had a peculiar fascination for Helps. A long essay is devoted to it in the first series of *Friends in Council*. This was subsequently elaborated into a work in two volumes published in 1848 and 1852, called *The Conquerors of the New World and their Bondsmen*. Helps's interest in the subject led him into further investigations into the history of the conquest of America by the Spaniards, and he went to Spain in 1817 for the special purpose of examining the numerous MSS. bearing upon the subject at Madrid. The fruits of these researches were embodied in an historical work based upon his *Conquerors of the New World*, and called *The Spanish Conquest in America, and its Relation to the History of Slavery and the Government of Colonies*. This appeared in four volumes during the years 1855, 1857, and 1861. No pains were spared by its author to secure the most scrupulous accuracy as to the facts with which he dealt. He had found, as most inquirers into the sources of history have found, that this accuracy is rarely to be met with in accepted histories. On this point he was determined that he should not be open to censure; and so anxious was he that fact should not be coloured or distorted by imagination that he deliberately resisted the temptation to use the picturesque method of treatment by which other writers on the same subject have secured popularity. The success of this work with the public was injured by other peculiarities. History, like fiction, will not bear to be written with an obtrusively moral purpose, as this book was written. Its merits in a literary point of view were also diminished by the author's tendency to suspend the onward movement of the narrative.

whilst he pauses to analyse character, to investigate motives, and to philosophize upon results.

This book, the result of years of research and meditation, was not a success. But the excellence of the studies of the great pioneers of Spanish conquest which it contained was quickly perceived when some years afterwards they were recast and published as separate biographies. Thus *The Life of Las Casas, the Apostle of the Indians*, appeared in 1868, *The Life of Columbus* in 1869, *The Life of Pizarro* in the same year, and *The Life of Hernando Cortes* in 1871. In this form all that is most important as well as attractive in the larger historical work has been placed within the reach of a wide circle of readers, to whom the result of Helps's researches otherwise would have been unknown.

From the time of his appointment as Clerk of the Council in 1860 to his death, Helps continued to add to the already considerable list of books, all dealing in one form or another with questions of social, sanitary, or political reform, which he had most earnestly at heart. No man felt more strongly that, in the words of Lamennais (*Livre du Peuple*, cap. i.), "things in this world are not as they ought to be." No man was more eager to do what he might towards obviating or curing the folly, stupidity, ignorance, lethargy, and selfishness to which so much of the misery, the ill-health, the suffering, and the sin of the world is due. It was a matter of conscience to do what he could towards "the relief of man's estate," by putting again and again before the world the results of his observation and thought upon its defective social and sanitary arrangements, and in this the reason is to be found for nearly all his books. Besides those which have been already mentioned the following may be named to complete the list:—*Organization in Daily Life, an Essay* (1862), *Realmah* (2 vols. 1869), *Casimir Marenna* (1870), *Brevia, Short Essays and Aphorisms* (1871), *Thoughts upon Government* (1872), *Life and Labours of Mr Thomas Brassey* (1872), *Ivan de Biron* (1874), *Social Pressure* (1875).

His appointment as Clerk of the Council brought him into personal communication with the Queen, and also with the late Prince Consort. They were not slow to find how valuable a servant they had obtained in him. His powers of mind, his gentle, reserved manners, and his tender almost chivalrous devotion to the sovereign, not demonstrated yet subtly making itself felt, produced their natural effect in winning the confidence and respect of these high personages. After the Prince's death, the Queen early turned to Helps to prepare such a sketch of the prince's character as might make her people aware how much they as well as herself had lost by his early death. The task was undertaken by Helps, and performed with all the excellence which might have been anticipated from his sympathy with the great aims and objects of the Prince's life, and his practised skill in the analysis and portrayal of character. His introduction to the collection, published in 1862, of the Prince Consort's speeches and addresses was the first, and will probably always be the standard, attempt to sketch in clear and vivid outlines the varied characteristics of this remarkable man. Helps some years afterwards edited and wrote an introductory preface to the series of extracts from the Queen's diary, which were published in 1868 under the title *Leaves from a Journal of Our Life in the Highlands*. In 1864 he received the honorary degree of D.C.L. from the university of Oxford. He was made a C.B. in 1871, and K.C.B. in the following year.

At no time of his life very strong, an obvious decline of vital strength, accelerated probably by anxiety from embarrassments in which his later years were involved by unfortunate speculations in the purchase of land, was visible to Sir Arthur Helps's friends for some years before his death.

This came after only a few days' illness on the 7th of March 1875.

Sir Arthur Helps was of middle height, slender, dark in complexion, with a high well-defined forehead, deep-set eyes, and a mouth the habitually grave expression of which was tempered by a pleasant smile, when his fancy was touched by the humorous suggestions of his own mind, or the playfulness or wit of others, to which he was peculiarly sensitive. Something of the delicacy of his frame entered into his manner and conversation, which were marked by an avoidance of everything approaching vehemence or even emphasis. He loved good talk, and his low vibrant voice and grave playfulness of mind were very pleasant, when among trusted friends he was tempted into taking an active part in the give and take of easy conversation. But he was in manhood what he was in youth, when we are told by one who knew him well, "he had not the physical force or the animal spirits which predispose novices to oral controversy." As a rule, he was more ready in general society to listen than to talk,—especially when people were present whose character was worth studying, or whose ideas were fresh and based upon experience or comprehensive study. He was always learning, and a new thought or pregnant suggestion dropped by a friend in conversation was often to be found soon afterwards in his writings carefully developed, and illustrated from his own fertile stores of reading and research. As might be expected from his books, there was a sympathetic charm in his familiar intercourse which was peculiarly fascinating. His sensitiveness to pain, especially to moral pain, was extreme, and would have unfitted him for much of the rough work and ways of the world. As an orator, a character for which he had many intellectual qualities, he could scarcely have failed to attain a high rank. He was himself not unconscious of his gifts in this direction; but he was altogether of too fine a fibre for the hard hitting and the fiery struggle of the political arena, in which alone he would have coveted distinction. Wiaely, therefore, he made for himself, as was well said by a friend at the time of his death, "work of another sort, applying his gentle ever busy mind to such discussion as purifies the thought, informs the pity, and confirms the forbearance of mankind." To the last his mind retained its vigour as well as its delicacy of perception. Nor would he have regarded it as among the least happy circumstances of his lot on earth that he was taken away before either of these had been touched by the palsy of decay—taken, moreover, swiftly and by no lingering illness to wear out the spirits of himself and those to whom he was dear. (T. MA.)

HELSINGBORG, a town of Sweden, province of Skane and län of Malmö, is beautifully situated at the narrowest part of the Sound—there only 3 miles wide—opposite Elsinore, and 32 miles N.N.W. of Malmö. It is connected with the Swedish railway by a branch line to Hesselholm, and Eslöf, and it has regular communication with Denmark by steamer. The harbour, completed in 1832, is sufficient for vessels of an ordinary size. The inhabitants are chiefly engaged in fishing, commerce, and agriculture. Corn is the principal export. A short distance north-east of the town there is a mineral spring, and about 2 miles south-east are the more famous wells of Ramlösa. The sea-baths to the north of the town are much frequented in summer. At Höganäs, about a mile and a half north, there are extensive coal-mines and also a pottery. The population, which in 1800 was only 1761, in 1860 was 5053, and in 1876 had reached 10,066.

Helsingborg is one of the oldest towns of Sweden. The original site is marked by the tower of Kärran (*i.e.* the churn), which was probably the strongest in the old fortress first mentioned in the year 1135. In the 14th century it was several times besieged. From 1370 it, along with the other towns of Skane, was joined for fifteen years to the Hanseatic League. The fortress having been laid waste by fire in 1418, King Eric of Pomerania about 1425 built a new fortress near the sea, and caused the town to be transplanted thither, bestowing upon it at the same time important privileges. Until 1658 it belonged to Denmark, and it was again occupied by the Danes in 1676 and 1677. In 1684 its fortifications were dismantled. It was retaken by Frederick IV. of Denmark in November 1709; but his troops, under General Rantzau, were severely defeated near it by General Stenbock, 10th March 1710, from which time it has remained in the possession of Sweden. In 1711 it was again bombarded by the Danes.

HELSINGFORS (Finnish, *Helsinki*), chief city of the grand-duchy of Finland and the government of Nyland, in the district Helsinge, on the Gulf of Finland, 274 miles by rail west of St Petersburg. The latitude of the observatory is 60° 9' 4" N., and longitude 24° 57' 39" E. from Greenwich.

The town is well laid out, with long and wide streets running at right angles. The houses are large and well built, and the principal square contains several fine buildings, as the senate-house, the university, and a magnificent church. Helsingfors has a colossal Russo-Greek cathedral, assembly-rooms, botanical gardens, an observatory well supplied with both astronomical and magnetic instruments, a beautifully decorated theatre, and other handsome public buildings. The university, removed from Åbo in 1827, has 4 faculties, 53 professors, and about 900 students, and possesses a museum with extensive natural history and mineralogical collections, an ethnological collection, and a chemical laboratory. There are scientific, literary, and other learned societies, a normal lyceum, polytechnic institute, school for the blind, school of navigation, asylum for the insane, hospitals, and other educational and charitable institutions. Helsingfors is the seat of the governor-general of Finland, the imperial senate, and all the central officers of the grand-duchy. In the hall of the senate-house is a splendid throne for the emperor; in the ritter-house the various branches of the assembly meet, and there also are the remains of the library saved from the fire of Åbo, and containing 15,000 volumes. Helsingfors has several machinery manufactures (one with 850 workpeople), and produces at the rate of £100,000 per annum; it has also porcelain, faience, sugar, and tobacco factories. There are two considerable harbours, with a handsome granite quay extending along the front of the town. In 1870 the population was 32,113, in 1879 about 40,000.

Helsingfors has the largest import trade in Finland, consisting mainly of wool, colonial and manufactured wares, salt, wine, &c., amounting in 1874 to £1,635,744, in 1878 to £3,748,487. The exports consist chiefly of wooden wares, the total amounting to £2,340,827 in 1878. Of the imports £437,100 came from, and of the exports £87,541 went to, England. In 1874 880 vessels of 153,717 registered tons entered the port, and in 1878 713 vessels of 73,297 tons; in 1874 980 of 159,549 tons cleared, and in 1878 825 of 132,170 tons. In 1876 the port possessed 43 vessels (18 of them steamers) of 4129 tons.

Helsingfors was founded by Gustavus Vasa in the 16th century, about 4 miles N.E. of the present site, to which it was removed by Queen Christina of Sweden in 1642. In 1742 it was the scene of the capitulation of the Swedes under Löwenhaupt; but in 1749 the fortress of Sveaborg was erected by the Swedish high admiral, Count Ehrenwerd, who at his own request was afterwards buried within its walls. In 1808 Admiral Cronstedt surrendered the place to the Russians under General Suhtalen. A combined squadron of the French and English bombarded Sveaborg in 1808.

See Brummer, *Historiska Uppgifter om Helsingfors*, 1874.

HELST, BARTHOLOMÆUS VAN DER, was born in Holland at the opening of the 17th century, and died at Amsterdam in 1670. The date and place of his birth are uncertain; and it is equally difficult to confirm or to deny the time-honoured statement that he was born in 1613 at Amsterdam. It has been urged indeed by competent authority that Van der Helst was not a native of Amsterdam, because a family of that name lived as early as 1607 at Haarlem, and pictures are shown as works of Van der Helst in the Haarlem Museum which might tend to prove that he was in practice there before he acquired repute at Amsterdam. Unhappily Bartholomew has not been traced amongst the children of Severija van der Helst, who married at Haarlem in 1607, and there is no proof that the pictures at Haarlem are really his; though if they were so they would show that he learnt his art from Frans Hals and became a skilled master as early as 1631. Scheltema, a very competent judge in matters of Dutch art chronology, supposes that Van der Helst was a resident at Amsterdam in 1636. His first great picture, representing a gathering of civic guards at a brewery, is variously assigned to 1639 and 1643, and still adorns the town-hall of Amsterdam. His noble portraits of the burgomaster Bicker and Andreas Bicker the younger, in the gallery of Amsterdam, of the same date no doubt as Bicker's wife

lately in the Ruhl collection at Cologne, were completed in 1642. From that time till his death there is no difficulty in tracing Van der Helst's career at Amsterdam. He acquired and kept the position of a distinguished portrait-painter, producing indeed little or nothing besides portraits at any time, but founding, in conjunction with Nicolaes de Helt Stokade, the painters' guild at Amsterdam in 1654. At some unknown date he married Constance Reynst, of a good patrician family in the Netherlands, bought himself a house in the Doelenstrasse, and ended by earning a competence. His likeness of Paul Potter at the Hague, executed in 1654, and his partnership with Backhuysen, who laid in the backgrounds of some of his pictures in 1668, indicate a constant companionship with the best artists of the time. Waagen has said that his portrait of Admiral Kortenaar, in the gallery of Amsterdam, betrays the teaching of Frans Hals, and the statement need not be gainsaid; yet on the whole Van der Helst's career as a painter was mainly a protest against the systems of Hals and Rembrandt. It is needless to dwell on the pictures which preceded that of 1648, called the Peace of Münster, in the gallery of Amsterdam. The Peace challenges comparison at once with the so-called Night Watch by Rembrandt, and the less important but not less characteristic portraits of Hals and his wife in a neighbouring room. Sir Joshua Reynolds was disappointed by Rembrandt, whilst Van der Helst surpassed his expectation. But Bürger asked whether Reynolds had not already been struck with blindness when he ventured on this criticism. The question is still an open one. But certainly Van der Helst attracts by qualities entirely differing from those of Rembrandt and Frans Hals. Nothing can be more striking than the contrast between the strong concentrated light and the deep gloom of Rembrandt and the contempt of chiaroscuro peculiar to his rival, except the contrast between the rapid sketchy touch of Hals and the careful finish and rounding of Van der Helst. The Peace is a meeting of guards to celebrate the signature of the treaty of Münster. The members of the Doele of St George meet to feast and congratulate each other not at a formal banquet but in a spot laid out for good cheer, where De Wit, the captain of his company, can shake hands with his lieutenant Waveren, yet hold in solemn state the great drinking-horn of St George. The rest of the company sit, stand, or busy themselves around,—some eating, others drinking, others carving or serving—an animated scene on a long canvas, with figures large as life. Well has Bürger said, the heads are full of life and the hands admirable. The dresses and subordinate parts are finished to a nicety without sacrifice of detail or loss of breadth in touch or impact. But the eye glides from shape to shape, arrested here by expressive features, there by a bright stretch of colours, nowhere at perfect rest because of the lack of a central thought in light and shade, harmonies, or composition. Great as the qualities of Van der Helst undoubtedly are, he remains below the line of demarcation which separates the second from the first-rate masters of art.

His pictures are very numerous, and almost uniformly good; but in his later creations he wants power, and though still amazingly careful, he becomes grey and woolly in touch. At Amsterdam the four regents in the Werkhuys (1650), four syndics in the gallery (1656), and four syndics in the town-hall (1657) are masterpieces, to which may be added a number of fine single portraits. Rotterdam, notwithstanding the fire of 1864, still boasts of three of Van der Helst's works. The Hague, as we saw, owns but one. St Petersburg, on the other hand, possesses ten or eleven, of various shades of excellence. The Louvre has three, Munich four. Other pieces are in the galleries of Berlin, Brunswick, Brussels, Carlsruhe, Cassel, Darmstadt, Dresden, Frankfort, Gotha, Stuttgart, and Vienna.

HELSTON, a municipal and parliamentary borough and market-town of England, county of Cornwall, is situated on the declivity of a hill on the river Cober, 9 miles S.W.

of Falmouth. It consists of four main streets intersecting each other at right angles; at their junction in the centre stands the market-house. The principal other buildings are the church dedicated to St Michael and built by the earl of Godolphin in 1763, the town-hall, the old coinage hall, the literary institute, the grammar school, and the union work-house. The prosperity of the town is due to its being the centre of an extensive agricultural and mining district. The principal manufacture is shoes. At Portheven, about 3 miles distant, a considerable export and import trade is carried on. Population of municipal borough (1871), 3797; of parliamentary borough (area 10,992 acres), 8760.

Helston is one of the original coinage towns. It obtained a charter from King John, and the privilege was conferred on it by Edward III. of holding a market and fairs. It was made a corporate town by Elizabeth. Before the Reform Act of 1832 it returned two members to parliament, but it now returns only one.

HELVETII. See SWITZERLAND.

HELVETIUS, CLAUDE ADRIEN (1715-1771), was descended from a family of physicians, the first of whom, John Frederick Schweitzer (Latinized into Helvetius), migrated from Germany to Holland about the year 1649, and became physician to the prince of Orange. His later years were spent in the study of alchemy. His son, John Adrien, also a physician, went to Paris in the hope of establishing a sale for his father's drugs. He failed in this attempt, but was so fortunate as to introduce with the greatest success the use of ipecacuanha, then an unknown drug. The duchess of Chaulnes, whom he had treated successfully, introduced him to Colbert, who recommended the young physician to the dauphin, after which his reputation was firmly established. His son, John Claude Adrien, who embraced the same career with even greater success, was appointed inspector-general of the military hospitals of Flanders and first physician to the Queen Marie Leczinska. He was remarkable for the generosity with which he received and visited poor patients who could pay him nothing. His son, Claude Adrien, the future author of *De l'Esprit*, showed as a boy little aptitude for study, but was fond of desultory reading. His father, who destined him for finance, placed him for a few years with his maternal uncle, M. D'Arman-court, "directeur des fermes" at Caen. There he learned all that was necessary for a profession so simple, and having plenty of spare time amused himself with writing verses and cultivating social graces. He was elected a member of the academy of Caen, and when he was only twenty-three years of age he had the singular good fortune to be appointed, at the queen's request, to a place as farmer-general; in other words, while still a very young man he was put into a post of great responsibility and dignity which was worth a hundred thousand crowns a year. Thus provided, young Helvetius proceeded to enjoy life to the utmost. He had every advantage except one, that of noble birth; he was the handsomest man of his time; he was possessed of a manner singularly charming; he was able to hold his own among the scholars and philosophers and poets; he was skilled in all those arts cultivated by gentlemen; he was generous like his father, and his great fortune enabled him to gratify his love of giving; he had an inclination to letters, and was a friend of Fontenelle, Voltaire, and Montesquieu, besides being a patron of such writers as Marivaux, Saurin, and Sabatier. Probably there was no young man in Paris in the years 1740 and 1750 who occupied a more enviable position or was more entirely contented with his lot than this spoiled child of fortune, on whose name there rested but one blot, an almost morbid desire to excel. So far indeed did he carry this passion for distinction that he once danced on the stage of the opera under the mask and name of the public favourite Javillier.

As he grew older, his social successes and *bonnes fortunes* naturally ceased; the splendour of his youth had vanished;

he began to dream of other and more lasting distinctions. Maupertuis, he observed, had put mathematics in fashion; he himself would be a mathematician. Voltaire was illustrious for poetry; he too would be a poet. Montesquieu had made so brilliant a success with his *Esprit des Loix* that he himself would become a philosopher. The mathematical dream seems to have produced nothing; his poetical ambitions resulted in his poem called *Le Bonheur*, in which he develops the idea that true happiness is only to be found in making the interest of one that of all; his philosophical studies ended in the production of his famous book *De l'Esprit*, the composition of which occupied him for more than seven years. In the year 1751 he married, his wife being a niece of Madame de Graffigny, the author of *Lettres d'une Péruvienne*; and he spent eight months in the year at his newly purchased estate of Voré in Le Perche; the remaining four months were given up to Paris and his duties of *maitre d'hôtel* to the queen. It was characteristic of the man that as soon as he thought his fortune sufficient for his wants he gave up his post of farmer-general. The history of his life in the country is full of anecdotes which illustrate his generous and kindly disposition: he relieved the poor, sent physicians to the sick, mediated between those who quarrelled, encouraged agriculture, developed industries, and found happiness in the patriarchal life of a French seigneur, being as great a stickler as any for his seigneurial rights. It was in 1758 that his book *De l'Esprit*, which was to be the rival of *L'Esprit des Loix*, appeared. It was so far successful at the very outset as to attract immediate attention and to arouse the most formidable opposition, at the head of which was the dauphin, son of Louis XV. The Sorbonne condemned the book; the priests persuaded the court that it was full of the most dangerous doctrines, and the author, terrified at the storm he had raised, wrote three separate retractations; yet, in spite of his protestations of orthodoxy, he had to give up his office at the court, and the book was publicly burned by the hangman. The virulence of the attacks upon the work, as much as its intrinsic merit, caused the whole world to read it; it was translated into almost all the languages of Europe; it was discussed in every literary circle. Yet the *Esprit des Loix* lives and is still studied with profit, while *De l'Esprit* has long since been forgotten. It is indeed difficult to understand that the work could ever have had any serious influence upon the thought of the time. Voltaire said it was full of commonplaces; Buffon maliciously said that "Helvétius aurait dû faire un livre de moins et un bail de plus dans les fermes du roi;" Rousseau declared that the very benevolence of the author gave the lie to his principles; Grimm thought that all the ideas in the book were borrowed from Diderot; Madsme du Defland said that Helvetius had raised such a storm by simply revealing the "great secret"; Madame de Graffigny averred that all the good things in the book had been picked up in her own salon.

As for the philosophy of the book, it belongs to the selfish school; the four discussions of which it consists have been thus summed up:—(1) all man's faculties may be reduced to physical sensation; memory, comparison, judgment, are only feeling; our only difference from the lower animals lies in our external organization; (2) our interest, founded on the love of pleasure and the fear of pain, is the only spring of our judgments, our actions, our affections; we have no liberty of choice between good and evil; there is no such thing as absolute right—ideas of justice and injustice change according to customs; (3) the inequalities of intellect do not depend on a more or less perfect organization, but have their cause in the unequal desire for instruction, and this desire springs from passions of which all men commonly well organized are susceptible to the same degree;

we can therefore all love glory with the same enthusiasm, and we owe all to education; (4) in this discourse the author treats of the ideas which are attached to such words as *genius, imagination, talent, taste, good sense, &c.* It is sufficient to add that, although the book was reprinted after the author's death, it ceased to have any influence even during his own life.

In 1764 Helvetius visited England, and the next year, on the invitation of Frederick, he went to Berlin, where the king paid him marked attention. He then returned to his country estate and passed the remainder of his life in perfect tranquillity. He died in 1771 at the age of fifty-six, leaving behind him a widow, who died in 1800, and two daughters.

A sort of supplement to the *De l'Esprit*, called *De l'Homme, de ses facultés intellectuelles et de son éducation*, was found among his manuscripts after his death, and was published, but created little interest. Editions of the work, however, appeared in 1772, 1773, and 1786. The complete works of Helvetius were published in 1774, 1777, 1781, 1794, 1795, and 1818. The best estimate of his work and place among the philosophers of the 18th century is that by Cousin (*Œuvres*, ii.). (W. BE.)

HELVIDIUS PRISCUS lived in the 1st century, during the reigns of Nero, Galba, Otho, Vitellius, and Vespasian. In those evil days he won the respect of all good men by his fearless love of freedom. Among the cringing and obsequious senators of Rome he dared to be sincere and outspoken. Tacitus says of him (*Hist.*, iv. 5) that in his early youth he devoted his great abilities to the highest pursuits, and made it his object to enter on public life with a spirit thoroughly fortified against all contingencies. It was natural that such a man should be a warm adherent of the Stoic school of philosophy. His father-in-law, Thrasea Pætus, had been the same; he had been driven to suicide in Nero's reign, and his last words to Helvidius were—"Young man, you have been born into times in which it is well to brace the spirit with examples of courage" (*Tacitus, Annals*, xvi. 35). Although he repeatedly offended the emperor, he held several high offices. During Nero's reign he was quæstor in the province of Achaia; he was also sent into Armenia in command of a legion, and by his good sense and moderation he succeeded in restoring peace and order in that country. By the provincials he was respected and trusted. His well-known sympathies with such men as Brutus and Cassius occasioned his banishment in 66 A.D., and he lived with his wife Fannia in Macedonia until Nero's death. Having been recalled to Rome by Galba in 68 A.D., he at once impeached Eprurius Marcellus, one of the most villainous of the informers, and the very man who had been the accuser of Thrasea Pætus. After an angry debate he dropped the charge, as the condemnation of Marcellus would have involved a host of senators in like ruin. As prætor-elect he had once the courage to oppose Vitellius in the senate, and again as prætor in the following year he ventured to argue against the financial policy of Vespasian. Such matters, he maintained, ought to be left to the discretion of the senate. He proposed that the Capitol, which had been destroyed in the Neronian conflagration, should be restored at the public cost. It would seem that he rather perversely went out of his way to insult Vespasian, saluting him by his private name, and not recognizing him as emperor in the edicts he had to publish as prætor. There was very possibly in all this some of the affectation which often characterized the Stoics. The end of it was that he was banished, his wife Fannia, whose constancy and virtue are highly commended by his friend the younger Pliny, going with him into exile. Shortly afterwards he was executed by Vespasian's order. His life was written at his widow's request by Herennius Seneccio; it took the form of a warm panegyric, and proved fatal to its author in the reign of Domitian.

HELVOETSLUYS (in Dutch, *Hellevoetsluis*), a fortified town of the Netherlands, in the province of South Holland, situated in the south of the island of Voorne-and-Putten, on the shore of the Haringvliet. It possesses a good harbour, a dry and a wet dock, extensive wharves, and a naval arsenal, and among its more important public buildings are the communal chambers, the Reformed church dating from 1661-1684, the Roman Catholic church, the synagogue, and the naval college. The population was only 1208 in 1795; by 1840 it had increased to 2523, and by 1874 it was 4135.

Helvoetsluys was founded in the 17th century. The construction of the dock was decreed by the states of Holland in 1636, and the erection of the fortifications in 1638; but it was not till 1696 that the works were completed. The new harbour soon became an important rendezvous for the Dutch fleet, and in 1688 it was the starting-point of William of Orange's expedition to England.

HELİYOT, PIERRE (1660-1716), monastic historian, was born at Paris in January 1660, of supposed English descent. After spending his youth in study, he entered in his twenty-fourth year the convent of the third order of St Francis, founded at Picpus, near Paris, by his uncle Jérôme Helyot, canon of St Sepulchre. There he took the name of Père Hippolyte. Two journeys to Rome on monastic business afforded him the opportunity of travelling over most of Italy; and after his final return he saw much of France, while acting as secretary to various provincials of his order there. Both in Italy and France he was engaged in collecting materials for his great work, which occupied him about twenty-five years, *L'Histoire des Ordres Monastiques, Religieux, et Militaires, et des Congrégations Séculières, de l'un et de l'autre Sexe, qui ont été établies jusqu'à présent*, published in 8 volumes in 1714-21. Helyot died on January 5, 1716, before the fifth volume appeared, but his friend Maximilien Bullot completed the edition. This work, appearing at first anonymously, has been republished several times, and translated into German. Helyot's only other noteworthy work is *Le Chrétien Mourant* (1695).

HEMANS, FELICIA DOROTHEA (1793-1835), was born in Duke Street, Liverpool, September 25, 1793. Her father, George Browne, of Irish extraction, was at the time of her birth a merchant in Liverpool, and her mother, whose maiden name was Wagner, was the daughter of the Austrian and Tuscan consul at Liverpool, and of united German and Italian descent. Felicia, the fifth of seven children, was scarcely seven years old when her father failed in business, and retired with his family to Gwrych, near Abergele; and there the young poetess and her brothers and sisters grew up in the wildest seclusion, in a romantic old house by the sea-shore, and in the very midst of the mountains and myths of Wales, the monotony of her young life being varied only by two visits to London, which she never revisited in after years. The little Felicia was a lovely, precocious child. Her education was desultory; and she may indeed be said to have educated herself, the only subjects in which she ever received regular instruction having been French, English grammar, and the rudiments of Latin. Books of chronicle and romance, and every kind of poetry, she read with avidity; and she studied Italian, Spanish, Portuguese, and German sufficiently to be able to read them with ease and enjoyment. She was also fond of music, and played on the harp and piano, her preference being for simple national and pathetic melodies, especially those of Wales and Spain. In 1808, when she was only fourteen, a quarto volume of her *Juvenile Poems* was published by subscription. Among the earliest of these were "Congratulatory Lines on her Mother's Birthday," "A Prayer," an "Address to the Deity," and some "Lines to Shakespeare,"—stiff, little, childish productions, which show, however, a good ear for rhythm and a considerable imitative faculty. The verses having been rather harshly

criticized in the *Monthly Review*, the little poetess was for some days in tears; but the muse was soon reawakened. One of her brothers was fighting in Spain under Sir John Moore; and Felicia, fired with military enthusiasm, wrote *England and Spain, or Valour and Patriotism*, a poem of some length and much elaboration, which was afterwards published and translated into Spanish. Her second volume, entitled *The Domestic Affections and other Poems*, appeared in 1812, on the eve of her marriage to Captain Hemans, which took place in the summer of that year. She lived for some time at Daventry, where her husband was appointed adjutant of the Northamptonshire militia; but about this time her father went on some commercial enterprise to Quebec and died there; and, after the birth of her eldest son, she and her husband took up their abode with her widowed mother at Bronwyllfa. Here during the next six years four more children—all boys—were born; but in spite of domestic cares and uncertain health she still read and wrote indefatigably. Her poem entitled *The Restoration of Works of Art to Italy* was published in 1816, her *Modern Greece* in 1817, and in the following year appeared her volume of *Translations from Camoens and other Poets*.

In 1818 Captain Hemans went to Rome, leaving his wife, shortly before the birth of their fifth child, with her mother at Bronwyllfa. No further explanation than that it was in the first instance for Captain Hemans's health has ever been offered of this step; there seems to have been then merely a tacit agreement, perhaps on account of their limited means, that they should live for a time apart. Letters were interchanged, and Captain Hemans was often consulted about his children; but the husband and wife remained separate, and indeed never met again. Kind and influential friends—among them the bishop of St Asaph and Bishop Heber—clustered round the poetess and her children. Her health, however, began to fail her, and her beauty, which was of a peculiarly delicate type, is said to have faded rapidly, leaving behind it an habitually worn and harassed expression. She became subject, too, to paroxysms of beating of the heart. Yet for the next six years her literary industry never flagged. In 1819 she published *Tales and Historic Scenes in Verse*, and in the same year she gained a prize of £50 offered for the best poem on *The Meeting of Wallace and Bruce on the Banks of the Carron*. The poem was published in *Blackwood's Magazine*. In 1820 appeared *The Sceptic and Stanzas to the Memory of the late King*. In June 1821 she won the prize awarded by the Royal Society of Literature for the best poem on the subject of *Dartmoor*, and during the same year she began her play, *The Vespers of Palermo*. She now applied herself to a course of German reading. Körner was her favourite German poet, and her lines on the grave of Körner were one of the first English tributes to the genius of the young soldier-poet. *The Voice of Spring*, one of her best known lyrics, was written in 1823, the same year in which she began to contribute to the *New Monthly Magazine*; and in the summer of 1823 a volume of her poems was published by Murray, containing "The Siege of Valencia," "The Last Constantine," and "Belshazzar's Feast," which last had appeared previously in a collection edited for a charitable purpose by Joanna Baillie. *The Vespers of Palermo* was acted at Covent Garden, December 12, 1823, and Mrs Hemans received £200 for the copyright; but, though the leading parts were taken by Young and Charles Kemble, the play was a failure, and was withdrawn after the first performance. It was acted again in Edinburgh in the following April with greater success, when an epilogue, written for it by Sir Walter Scott at Joanna Baillie's request, was spoken by Mrs Henry Siddons. An interchange of notes on this subject was the beginning of a cordial friendship between Mrs Hemans and the novelist. In the same year she wrote *De Chatillon, or the Crusaders*;

but the manuscript was mysteriously lost, and the poem was not published till two years after her death, and then from a rough copy. In 1824 she began "The Forest Sanctuary," which appeared a year later with the "Lays of Many Lands" and miscellaneous pieces collected from the *New Monthly Magazine* and other periodicals.

In the spring of 1825 Mrs Hemans, with her mother and children and an unmarried sister, removed from Bronwyllfa, which had been purchased by her brother, to Rhyllon, another house belonging to him on an opposite height across the river Clwyd. The contrast between the two houses suggested her *Dramatic Scene between Bronwyllfa and Rhyllon*. The house itself was bare and unpicturesque, but the beauty of its surroundings has been celebrated in "The Hour of Romance," "To the River Clwyd in North Wales," "Our Lady's Well," and "To a Distant Scene." This time seems to have been the most tranquil in Mrs Hemans's life. Her children were growing up about her; her own variable health was at its best; her popularity was spreading, not only in England but in America, where Professor Norton of Harvard university undertook to superintend the publication of a complete edition of her works and to secure to her the profits. But the death of her mother in January 1827 was a second great breaking-point in her life. Her own health began to alarm her; and though the nature of her illness, which afterwards proved heart complaint, was not at first apparent, she was from this time an acknowledged invalid. In the summer of 1828 the *Records of Woman* was published by Blackwood, and in the same year the home in Wales was finally broken up by the marriage of Mrs Hemans's sister and the departure of her two elder boys to their father in Rome. Mrs Hemans therefore left Rhyllon, and took a very small house in the village of Wavertree, near Liverpool, where she hoped to obtain good schooling for her children and society for herself. But, although she had a few intimate friends there,—among them her two subsequent biographers, Henry F. Chorley and Mrs Lawrence of Wavertree Hall,—she was disappointed in her new home. She thought the people of Liverpool stupid and provincial; and they, on the other hand, found her uncommunicative and eccentric. In the following summer she travelled by sea to Scotland with two of her boys, to visit the Hamiltons of Chiefswood. This visit to Scotland was one of the most daring feats, and perhaps the richest episode, in her uneventful life. She was cordially welcomed in Edinburgh, dined with Jeffrey and other celebrities, visited Henry Mackenzie, heard Alison preach, and stayed with Sir David and Lady Wedderburn, and with Sir Robert Liston at Milburn, where she sat for a bust to Angus Fletcher. Above all, while she was at Chiefswood, she enjoyed "constant, almost daily, intercourse" with Sir Walter Scott, with whom she and her boys afterwards stayed some time at Abbotsford. "There are some whom we meet, and should like ever after to claim as kith and kin; and you are one of those," was Scott's compliment to her at parting. One of the results of her Edinburgh visit was an article, full of praise, judiciously tempered with criticism, by Jeffrey himself for the *Edinburgh Review*. The poetess returned to Wavertree to compose her *Songs of the Affections*, which were published early in 1830. In the following June, however, she again left home, this time to visit Wordsworth and the Lake country; and in August she paid a second visit to Scotland. She was resolved to leave Wavertree, and wished to make Edinburgh her home; but the climate was pronounced too rigorous, and, as a brother and his family were already settled in Ireland, it was arranged that she should go to live in Dublin. In her new home kind friends and admirers gathered round the invalid, who now had with her only the youngest of her children. She was obliged

to lie constantly, and the exertion of writing began to be painful to her. Her poetry of this date is chiefly religious. Early in 1834 her *Hymns for Childhood*, which had appeared some years before in America, were published in Dublin. At the same time appeared her collection of *National Lyrics*, and shortly afterwards *Scenes and Hymns of Life*. She was planning also a series of German studies, to consist of translations from German authors, with introductions and explanatory notes, one of which, on Goethe's *Tasso*, was completed and published in the *New Monthly Magazine* for January 1834. In intervals of acute suffering she wrote the lyric *Despondency and Aspiration*, and dictated a series of sonnets called *Thoughts during Sickness*, the last of which, "Recovery," was written when she fancied she was getting well. After three months spent at Redesdale, Archbishop Whately's country seat, which had been placed at the disposal of the dying poetess, she was again brought into Dublin, where she lingered till spring. The use of her limbs was entirely gone; but her passion for reading remained to the last, and the table at her bedside was strewn with books, one of which always lay open. Her last poem, the *Sabbath Sonnet*, was dictated to her brother on Sunday April 26th, and she died on the evening of Saturday, May 16, 1835, at the age of forty-one. She was buried in a vault under St Anne's church, Dublin. Besides the bust of Mrs Hemans by Angus Fletcher, there were three portraits taken of her in 1827 by the American painter West, one of which has been engraved; and another portrait, an engraving of which is in Chorley's *Memorials*, was painted in 1831 by a young Irish artist, Edward Robinson.

Mrs Hemans's poetry is the production of a fine imaginative and enthusiastic temperament, but not of a commanding intellect or very complex or subtle nature. It is the outcome of a beautiful but singularly circumscribed life, a life spent in romantic seclusion, without much worldly experience, and warped and saddened by domestic unhappiness and real physical suffering. Perhaps from these circumstances, aided by a course of self-instruction at best desultory and unguided, the emotional in a sensitive and intensely feminine nature was unduly cultivated; and this undue preponderance of the emotional is a prevailing characteristic in Mrs Hemans's poetry, and one to which Scott alluded when he complained that it was "too poetical," that it contained "too many flowers" and "too little fruit." Her genius—beautiful and pleasing as it was—was not of a very high order. Like her favourite music, it lay within a small compass, and gave little opportunity for intricate harmonies. Thus her tragedies, and her longer and more complicated poems, such as *The Sceptic* and *Forest Sanctuary*, though by no means devoid of striking passages, are the least notable of her works. It is not, however, as the writer of these more ambitious productions, which in her own time were but doubtful successes and are now rarely read, but as the authoress of many short occasional pieces, and especially as a lyricist, that Felicia Hemans has earned so high a place among our poets. In her lyrics she could concentrate her strength on the perfect expression of simple themes. Her skill in versification, her delicate ear for rhythm, and the few ruling sentiments of her nature here found ample scope. In her lyrics Mrs Hemans is uniformly graceful, tender, delicately refined,—sometimes perhaps, even here, too fervent, too emotional,—but always pure and spiritual in tone; and in these too she occasionally displays those rarer qualities which belong only to the finest lyric genius. Many of her poems, such as "The Treasures of the Deep," "The Better Land," "The Homes of England," "Casabianca," "The Palm Tree," "The Graves of a Household," "The Wreck," "The Dying Improvisatore," and "The Lost Pleiad," have become standard English lyrics, and on the

strength of these, and others such as these, Felicia Hemans is ranked among our chief British lyrical poets.

An edition of Mrs Hemans's *Poetical Works* was published, 2 vols., in 1832; *Poetical Remains*, with Memoir by Delta, 1836; *Memorials*, &c., by H. F. Chorley, 1836; *Recollections of Mrs Hemans*, by Mrs Lawrence, 1836; *Works of Mrs Hemans, with a Memoir of her Life*, by her sister (Mrs Hughes), 7 vols., 1839, and American reprint, 2 vols., 1847; *Early Blessings, a Collection of Poems written between eight and fifteen years of age*, with a Life of the Authoress, 1840; *Poems*, chronologically arranged, Edin., 1849; *Poems*, copyright edition, Edin. and London, 1872; *Poetical Works*, with critical memoir by W. M. Rossetti, London and Edin., 1873. (F. M.)

HEMEL-HEMPSTEAD, a market-town of England, county of Hertford, is pleasantly situated on the declivity of a hill near the river Gade, 23 miles N.W. of London, $1\frac{1}{2}$ miles from the Boxmoor station of the London and North-Western Railway, and on a branch line of the Midland Railway. The town consists almost wholly of one main street about a mile in length. Among the principal buildings are the parish church, cruciform in shape, and partly Norman in style, surmounted by a lofty octagonal spire, and containing an old brass of the time of Edward III.; the town-hall, a long narrow building formerly supported on square wooden pillars, but whose open market place underneath has now been converted into a corn exchange; the union workhouse, and the West Herts infirmary. The chief industry is straw plaiting, but there are also manufactories of paper, an iron foundry, breweries, and tanneries. The population of the township in 1871 was 5996, and of the parish 8720.

From its name, meaning high stead or place, the town is apparently of Saxon origin. In Domesday it is written Henainsteda and Hanelamestede. It received a charter of incorporation from Henry VIII., which was renewed by Cromwell. It still makes annual choice of a bailiff, but he possesses no magisterial authority.

HEMEROBAPTISTS, an ancient Jewish sect, so named from their observing a practice of daily ablution as an essential part of religion. Epiphanius, who mentions their doctrine as the fourth heresy among the Jews, classes the Hemerobaptists doctrinally with the Pharisees, from whom they differed only in, like the Sadducees, denying the resurrection of the dead. The name has been sometimes given to the Mendaeans on account of their frequent ablutions; and in the *Clementine Homilies* (ii. 23) St John the Baptist is spoken of as a Hemerobaptist. Mention of the sect is made by Hegesippus (see Euseb., *Hist. Eccl.*, iv. 22) and by Justin Martyr in the *Dialogue with Tryphon*.

HJUMINGFORD, or HEMMINGFORD, WALTER, a Latin chronicler of the 14th century, was a canon regular of the Austin Priory of Gisborough, now Guisborough, in Yorkshire. Leland calls him Hemengoburgus, and in one of the manuscripts of his chronicle his name appears as Hemingburght. In a document of the priory the name is also given as De Homingburgh; and in Gisborough Chartulary mention is made of a neighbouring family of that name. Bale seems to have been the first to give him the name by which he is more commonly known. His chronicle embraces the period of English history from the Conquest (1066) to the nineteenth year of Edward III., with the exception of the latter years of Edward II. It ends with the title of a chapter in which it was proposed to describe the battle of Crécy (1346); but the chronicler seems to have died before the required information reached him. In compiling the first part, Hemmingford apparently used the histories of Eadmor, Hoveden, Henry of Huntingdon, and William of Newbury; but the reigns of the three Edwards are original, composed from personal observation and information. There are several manuscripts of the history extant,—the best perhaps being that presented to the College of Arms by the earl of Arundel. The work is correct and judicious, and written in a pleasing style. One of its special features is the preservation in its pages of copies of

the great charters; and Hemingford's versions have more than once supplied deficiencies and cleared up obscurities in copies from other sources.

The first three books were published by Dr Thomas Gale in 1687, in his *Historia Anglicana Scriptores Quinque*, and the remainder by Hearn in 1731. The first portion was again published in 1848 by the English Historical Society, under the title *Chronicon de Gestis Regum Angliæ*, edited by H. C. Hamilton.

HEMIPTERA (*ἡμι-*, half, and *πτερόν*, wing), an order of the *Insecta* most commonly known by the name of "bugs," and containing the species so well known to infest houses. In their earlier stages they have what is known amongst naturalists as an incomplete metamorphosis; that is to say, after quitting the egg, and during the two stages of their existence before assuming the perfect form, they move freely about, thus unlike the *Lepidoptera*, &c., whose pupa state, or that preceding the perfection of the insect, is quiescent. When the transformations have been completed, the insect generally possesses four wings. The superior pair, or hemielytra as they are called by authors, are attached to the mesothorax, and are composed of two substances,—the basal portion coriaceous, or resembling leather, and the apical one membranaceous, or resembling thin, transparent parchment. The lower pair are attached to the metathorax, and are entirely membranous and generally transparent, and capable of being folded when the insect is in repose. This segment of the sternum likewise bears on each side, anteriorly, a more or less reniform-shaped orifice, within which lies a sac containing the fluid or matter from which so many of the *Heteropterous* portion of the order emit a most disagreeable odour. They also possess in all stages a mouth (rostrum) composed of three or more joints formed for suctional purposes.

The order is divided into two sub-orders, *Hemiptera-Heteroptera* and *Hemiptera-Homoptera*, and these again are separated into divisions and subdivisions, the latter being distributed into families which contain the various genera and species. In the first sub-order (*Hemiptera-Heteroptera*) there are two divisions, viz., *Gymnocerata* and *Cryptocerata*, and the families comprised under these heads are 69 in number, the following being the generally accepted order in which they are arranged, viz.: *Pachycoridae* (in this family the scutellum is so enlarged as to cover the whole of the upper side of the abdomen, both pairs of wings being concealed beneath it when not in flight; in one genus at least the species might be mistaken for some of the *Buprestidae* in *Coloptera*, which they resemble in form and brilliancy of colour), *Eurygastridae*, *Podopidae*, *Odontoscelidae*, *Plataspidae*, *Ozynotidae*, *Asopidae*, *Cydnidae*, *Sciocoridae*, *Phlaeidae* (this last contains but one genus, the species of which are most peculiar in appearance, as they resemble small, thin pieces of bark joined together), *Halydidae*, *Pentatomidae*, *Urostylidae*, *Edessidae*, *Phylloxeridae*, *Megymnidae*, *Spartocoridae*, *Mictidae*, *Nematopidae*, *Homocoridae*, *Syrmastidae*, *Acanthocoridae*, *Misoscelidae*, *Alydidae*, *Stenocephalidae*, *Berytidae*, *Coreidae*, *Rhopalidae*, *Lygaeidae*, *Dipsocoridae*, *Anthecoridae*, *Microphysidae*, *Tyrhacoridae*, *Largidae*, *Capsidae*, *Phymatidae*, *Macrocephalidae*, *Hebridae*, *Zosmenidae*, *Piesmidæ*, *Tingitidae*, *Brachyrhynchidae*, *Aradidae*, *Acanthiidae*, *Holoptilidae*, *Lobocephalidae*, *Syeonidae*, *Harpactoridae*, *Saccocoridae*, *Hæmatocoridae*, *Tagalidae*, *Stenopodidae*, *Reduviidae*, *Ectrichodidae*, *Apiomeridae*, *Piratidae*, *Nabidae* (the species comprised in the last 12 families are predaceous in their habits, and the larva of one species, *Reduvius personatus*, is known to prey upon the common house bug, *Acanthia lectularia*; some two or three of the species in South America are also known to live with spiders), *Sallidae*, *Pelagonidae*, *Emesidae*, *Hemicephalidae*, *Gerridae*, *Velidae*, *Galgulidae*, *Naucoridae*, *Belostomidae*, *Nepidae*, *Corixidae*, and *Notonectidae* (the species pertaining to the last eight families, except the *Galgulidae*, live either in or on the water, and the genus *Belostoma* contains the largest insect of the order, *Belostoma grandis*, which measures 3½ inches in length by nearly 1½ in breadth). In the second sub-order (*Hemiptera-Homoptera*) there are three grand divisions, viz., *Cicadina*, *Phytophthires*, and *Anoptura*. The first embraces the families *Stridulantiidae*, *Fulgoridae*, *Tectigometridæ*, *Aembracidae*, and *Cicañidae*; and in these families are to be found perhaps some of the most curious and wonderful forms of insect life. The well known lantern-fly (*Fulgora lateritaria*, L.) belongs here, and the whole of the stridulating or singing group is also included. The *Phytophthires*, or second division, contains three families, viz., *Psyllidae*, *Aphididae*, and *Coccidae*. None of the insects composing this group are of large size, and many of them are only about one

line in length. The first family affects trees and plants, in many instances distorting the leaves, and buds; one of its species, *Rhinocola speciosa*, has been recorded by Lichtenstein in the annals of the French Entomological Society for 1872 as puncturing poplar leaves which afterwards attain the size and form of a cucumber. The *Psyllidae* differ from the second family in having the power to leap, their third pair of legs being formed for this purpose. The *Aphididae* are perhaps best known by the terms "blight," "green fly," &c. These are to be found almost always in large companies on nearly every kind of tree, plant, and shrub. They are said to produce the honey dew found upon maple and other trees, although this has been disputed by Dr Hooker in the *Gardener's Chronicle* for July 1873. They are furnished with two setiform pipes or tubes, varying considerably in length in the different species, placed one on each side of the abdomen on the fourth segment from the apex, from which certainly is emitted a sweet fluid which the ants are well known to follow them for and consume. This family also contains the great vine-pest known by the name of *Phylloxera vastatrix*. The third family, *Coccidae*, has amongst its members the well-known cochineal insect (*Coccus Cacti*), from the female of which when gathered and killed is obtained the drug or dye used in giving the red colours, scarlet and crimson. It is also used for making carmine. The last division to be dealt with is called the *Anoptura*, and contains the most degraded forms of the whole order, viz., the lice, the fullest information concerning which may be obtained by consulting the works of Nitzsch, Burmeister, Leach, and Denny.

Although the *Hemiptera* are of very ancient date, remains of some of the fossil forms having been found in the Primary and other formations, the number of these is but few; they are enumerated in a paper on "Fossil Entomology" by Mr H. Goss in vol. xv. of the *Entomologist's Monthly Magazine*.

The whole of the group is extremely widely distributed, being found in almost every portion of the globe; and they are very varied both in form and in their modes of life,—man, animals, birds, insects, and plants being subjected to their attacks. On the Continent they have for a long period engaged the attention of naturalists, but in England little was known of the actual number inhabiting these islands until Douglas and Scott in 1865 published their volume of *British Hemiptera-Heteroptera*. In 1859 Dr A. Dohrn published what may be considered to be the first whole-world catalogue of the order; and, taking it as a basis, for there is no other approximate list, and adding a reasonable amount of new species collected in each year since that time, their number would amount to nearly 10,500 species, 5300 belonging to the heteropterous section and the remainder to the second sub-order. Out of these Europe lays claim to at least 3000, whilst Great Britain is known to possess not fewer than 1000. There is no record of any one of the species being cosmopolitan (except perhaps the house bug, *Acanthia lectularia*), although some of the species inhabiting England are also to be met with in China and Japan. (J. sc.)

HEMLING. See **MEMLING.**

HEMLOCK is the *Conium maculatum* of botanists, a biennial umbelliferous plant, found wild in many parts of Great Britain and Ireland, where it occurs in waste places, on hedge-banks, and by the borders of fields, and which is also widely spread over Europe and temperate Asia, and naturalized in the cultivated districts of North and South America. It is an erect branching plant, growing from 3 to 6 feet high, and emitting a disagreeable smell, like that of mice. The stems are hollow, smooth, somewhat glaucous, green, spotted with dull dark purple, as alluded to in the specific name, *maculatum*. The root-leaves have long furrowed footstalks, sheathing the stem at the base, and are large, triangular in outline, and repeatedly divided or compound, the ultimate and very numerous segments being small, ovate, and deeply incised at the edge. These leaves generally perish after the growth of the flowering stem, which takes place in the second year, while the leaves produced on the stem become gradually smaller upwards. The branches are all terminated by compound

many-rayed umbels of small white flowers, the general involucre consisting of several, the partial ones of about three short lanceolate bracts, the latter being usually turned towards the outside of the umbel. The flowers are succeeded by broadly ovate fruits, the mericarps (half-fruits) having five ribs which, when mature, are waved or crenated; there are no vittæ or oil-cysts; and when cut across the albumen is seen to be deeply furrowed on the inner face, so as to exhibit in section a reniform outline. The fruits when triturated with a solution of caustic potash evolve a most unpleasant odour.

Hemlock is a virulent poison, but it varies much in potency according to the conditions under which it has grown, and the season or stage of growth at which it is gathered. In the first year the leaves have little power, nor in the second are their properties developed until the flowering period, at which time, or later on when the fruits are fully grown, the plant should be gathered. The wild plant growing in exposed situations is to be preferred to garden-grown samples, and is more potent in dry warm summers than in those which are dull and moist.

The poisonous property of hemlock resides chiefly in the alkaloid *conine* or *coniia* which is found in both the fruits and the leaves, though in exceedingly small proportions in the latter. Conine resembles nicotine in its deleterious action, but is much less powerful. No chemical antidote for it is known. The plant also yields a second less poisonous crystallizable base called *conhydrine*, which may be converted into conine by the abstraction of the elements of water.

When collected for medicinal purposes, for which both leaves and fruits are used, the former should be gathered at the time the plant is in full blossom, while the latter are said to possess the greatest degree of energy just before they ripen. The fruits are the chief source whence conine is prepared. The principal forms in which hemlock is employed are the extract and juice of hemlock, hemlock poultice, and the tincture of hemlock fruits. Large doses produce vertigo, nausea, and paralysis; but in smaller quantities, administered by skilful hands, it has a sedative action on the nerves. It has also some reputation as an alterative and resolvent, and as an anodyne.

The acrid narcotic properties of the plant render it of some importance that one should be able to identify it, the more so as some of the compound-leaved umbellifers, which have a general similarity of appearance to it, form wholesome food for man and animals. Not only is this knowledge desirable to prevent the poisonous plant being detrimentally used in place of the wholesome one; it is equally important in the opposite case, namely, to prevent the inert being substituted for the remedial agent. The plant with which hemlock is most likely to be confounded is the *Anthriscus sylvestris*, or cow-parsley, the leaves of which are freely eaten by cattle and rabbits; this plant, like the hemlock, has spotted stems but they are hairy, not hairless; it has much-divided leaves of the same general form, but they are downy and aromatic, not smooth and nauseous when bruised; the fruit of the *Anthriscus*, besides, is linear-oblong and not ovate.

HEMP, *Cannabis sativa*, an annual herb, having angular rough stems and alternate lobed leaves. The bast fibres of *Cannabis* are the hemp of commerce, but under the name of hemp fibrous products from many different plants are often included. Sunn hemp is the bast fibre of a papilionaceous plant, *Crotolaria juncea*, of India and the Sunda Islands; *Hibiscus cannabinus*, an Indian malvaceous plant, yields brown or Bombay hemp; Jute or Pant hemp is produced by *Corchorus capsularis* and *C. olitorius*, and to some extent by *C. fuscus*, *C. fascicularis*, and *C. decemangulatus*. Manila hemp or feather fibre is derived from

the fibro-vascular bundles of certain monocotyledons, namely, several species of *Musa*, chiefly from *M. textilis*, but to some extent from *M. sapientum*, *M. ensete*, *M. mindanensis*, and *M. Cavendishii*, in India, New Guinea, the Philippines, &c. Pita hemp is produced from certain species of *Agave*; the *Aloe sisalina* of Central America yields grass-hemp; and Murva or bowstring-hemp is obtained from an aloe-like plant, *Sansevieria zeylanica*, in Bengal, Ceylon, Java, and southern China.

The hemp plant, like the hop, which is the other member of the same natural order, *Cannabaceæ*, is dioecious, that is, the male and female flowers are borne on separate plants. The male plant is smaller than the female, and ripens and dies earlier in the summer. The foliage of the female plant is darker and more luxuriant than that of the male. The leaves of hemp are constituted of 5 to 7 leaflets, the form of which is lanceolate-acuminate, and sharply serrate. The loose panicles of male flowers and the short spikes of female flowers arise from the axils of the upper leaves. The height of the plant varies greatly with season, soil, and manuring; a variety (*C. sativa*, var. *gigantea*) has produced specimens over 17 feet in height, but the average height of the common sort is about 8 to 10 feet. There is but one species of hemp known, *Cannabis sativa*, the *C. indica*, Lam., and *C. chinensis*, DeCille, owing their differences to climate, and losing many of their peculiarities when cultivated in temperate regions. Rumphius (in the 17th century) had noticed these differences between Indian and European hemp.

The original country of the hemp-plant was doubtless in some part of temperate Asia, probably near the Caspian Sea. It spread westward throughout Europe, and southward through the Indian peninsula.¹

Wild hemp still grows on the banks of the Lower Ural and the Volga, near the Caspian Sea. It extends to Persia, the Altai range, and northern and western China. It is found in Kashmir, and on the Himalaya, growing vigorously as far up as 6000 or even 10,000 feet.

Hemp is grown for three products—(1) the fibre of its stem; (2) the resinous secretion which is developed in hot countries upon its leaves and flowering heads; (3) its oily seeds.

Hemp has been employed for its fibre from ancient times. Herodotus (iv. 74) mentions the wild and cultivated hemp of Scythia, and describes the hempen garments made by the Thracians as equal to linen in fineness. Hesychius says the Thracian women made sheets of hempen. Moschion (about 200 B.C.) records the use of hempen ropes for rigging the ship "Syracusia" built for Hiero II. The hemp plant has been cultivated in northern India from a considerable antiquity, not only as a drug but for its fibre. The Anglo-Saxons were well acquainted with the mode of preparing hemp. Hempen cloth became common in central and southern Europe in the 13th century.

The medicinal and intoxicating properties of hemp have probably been known in Oriental countries from a very early period. An ancient Chinese herbal, part of which was written about the 5th century B.C., while the remainder is of still earlier date, notices the seed and flower-bearing kinds of hemp. Other early writers refer to hemp as a

¹ The names given to the plant and to its products in different countries are of interest in connexion with the utilization of the fibre and resin. In Sanskrit it is called *gomi*, *sana*, *shanapu*, *bang*, and *ganjika*; in Bengali, *ganga*; Persian, *bang* and *canna*; Arabic, *kinnub* or *cannab*; Greek, *kannabis*; Latin, *cannabis*; Italian, *canappa*; French, *chanvre*; Spanish, *cáñamo*; Portuguese, *cánamo*; Russian, *konopel*; Lettish and Lithuanian, *kannapes*; Slavonic, *konopi*; Erse, *cannaib* and *canab*; Anglo-Saxon, *hæneþ*; Dutch, *hennep*; German, *hanf*; English, *hemp*; Danish and Norwegian, *hamp*; Icelandic, *hampr*; and in Swedish, *hampa*. The English word *canvas* sufficiently reveals its derivation from *cannabis*.

remedy. The medicinal and dietetic use of hemp spread through India, Persia, and Arabia in the early Middle Ages. The use of hemp (jhang) in India was noticed by Garcia d'Orta in 1563. Berlu in his *Treasury of Drugs* (1690) describes it as of "an infatuating quality and pernicious use." Attention was recalled to this drug, in consequence of Napoleon's Egyptian expedition, by De Sacy (1809) and Rouger (1810). Its modern medicinal use is chiefly due to trials by Dr O'Shaughnessy in Calcutta (1838-1842). The plant is grown partly and often mainly for the sake of its resin in Persia, northern India, and Arabia, in many parts of Africa, and in Brazil.

The hemp plant grown in some parts of the United States yields the active resin so freely that less than 1 grain of the extract is a full dose. But it is as a fibre-producer that the hemp is now being more extensively cultivated in the United States. Hemp seeds were ordered for Plymouth colony as early as 1629, but the greater profit derivable from tobacco has always opposed the development of hemp-growing. The plant is chiefly grown in the States of Kentucky, Missouri, Tennessee, Ohio, Indiana, and New York. The produce of Kentucky in 1877 was 6140 tons. According to the census of 1870 the total production of the United States was 12,746 tons. In the northern part of the State of New York the crop is valued chiefly for the seeds, which may be from 20 to 40 bushels or more per acre. The produce per acre in the United States is from 700 to 1000 lb of fibre, 4 to 6 pecks of seed being usually sown.

Although the hemp-plant is grown in India chiefly for the production of its narcotic or intoxicating resin, yet a good deal of true hemp fibre is produced there. It is imported into England, however, chiefly from Russia, the United States, Italy, Holland, Germany, Hungary, and Turkey. It is grown in Ireland, and in some parts (Suffolk and Lincolnshire) of England. It thrives well in Algeria. It requires a rich deep soil and heavy manuring, and is an exhausting crop. In Great Britain about 6 pecks of seed per acre are drilled, 18 inches apart, in the middle of April. The male plants are pulled from the end of July to the end of August, the female or seed-bearing plants being gathered in September.

The British imports of hemp cannot be ascertained with accuracy, as the official returns include under that name the fibres of many hemp-substitutes. The following statement of hemp imported into the United Kingdom must therefore be taken with all necessary reserve:—

1873.....	1,247,354 cwts.	1876.....	1,174,859 cwts.
1874.....	1,240,168 "	1877.....	1,254,667 "

The following table gives the sources whence the supplies were chiefly drawn in the year 1877. But it must be again observed that the figures given for the imports from India, the Philippines, and other places to a less degree, include Manila hemp, Sunn hemp, and other spurious hems.

Imports of Hemp into the United Kingdom in 1877.

There were sent out 11,790 cwts. dressed English-grown hemp, more than half of this going to France. 14,676 cwts. of foreign and colonial dressed hemp were re-exported to British America and other countries, with 133,516 cwts. rough hemp, and 197 cwts. codilla.

Nearly all the hemp imported into the United Kingdom is landed at Liverpool, London, Hull, and Leith. Most of it is employed in the manufacture of cables, ropes, cordage, twine, sacking, tar-

paulins, canvas, and sailcloth. The finest hemp comes from Italy, but it is almost equalled by the higher qualities of the Russian fibre. Russian hemp varies much in price, according to quality and market fluctuations; its price in November 1879 was from £23 to £25 per ton, Italian or garden hemp fetching from £38 to £41.

In order to free the fibre of the hemp plant from the soft and nseles pareuchyma and the tissues of the bark, the stems are submitted to nearly the same processes as those described in the article FLAX. They are dried, beaten, or crushed in a hemp mill, and fermented or *retted*, preferably in soft water, after which they are again beaten with wooden mallets or in a specially constructed machine called a *break*. After breaking the stems are *scutched*, and thus the separation of the fibres furthered by the rubbing and striking to which they are subjected. The fibres are then *hackled* or *combed*.

According to Vétillart, the average length of European hemp fibres is .86 inch, the extremes being .2 and 2.1 inches. Dr M'Nab gives .0005 to .0007 inch as the diameter of fibres, the central cavity being .0001 in breadth. Under the microscope hemp fibres resemble those of flax, both being bast-fibres, and differ widely from those of Manila hemp or New Zealand flax; they are longitudinally striated cylinders, sometimes free and sometimes associated in small bundles. A hemp cord of 1 square millimetre section will bear, according to Haberlandt, an average weight of 34.5 kilogrammes without breaking—sometimes as much as 50 kilos.

The chief constituent of the fibre of hemp is of course cellulose, but small quantities of other substances are always present—the purest aorts, however, being richest in cellulose. A fine sample of Italian hemp gave on analysis the following percentages—water 8.9, wax 0.6, ash 0.8, matters soluble in water 3.5, lignose, albuminoids, &c., 8.4, cellulose 77.8. An ordinary sample of Russian hemp contained no less than 10.5 per cent. of moisture, and 1.5 of mineral matter, with but 72 of pure cellulose. By boiling a portion of this sample for four hours with water in a sealed tube at 150° C., a soluble extract amounting to 1/10th of the original hemp was obtained, Manila hemp giving 15.4 per cent., and Phormium fibre no less than 19 per cent., when similarly treated. Dilute solutions of iodine and sulphuric acid, successively applied, give to hemp fibres a greenish hue. The ash of hemp is rich in lime.

Hemp-resin.—Hemp as a drug or intoxicant for smoking and chewing occurs in the three forms of bhang, ganja, and charas.

(1) *Bhang*, the Hindustani *siddhi* or *sabzi*, consists of the dried leaves and small stalks of the hemp; a few fruits occur in it. It is of a dark brownish-green colour, and has a faint peculiar odour and but a slight taste. It is smoked with or without tobacco; or it is made into a sweatmeat with honey, sugar, and aromatic spices; or it is powdered and infused in cold water, yielding a turbid drink, *subdschi*. *Hashish* is one of the Arabic names given to the Syrian and Turkish preparations of the resinous hemp leaves. One of the commonest of these preparations is made by heating the bhang with water and butter, the butter becoming thus charged with the resinous and active substances of the plant.

(2) *Ganja*, the guaza of the London brokers, consists of the flowering and fruiting heads of the female plant. It is brownish-green, and otherwise resembles bhang, as in odour and taste. Some of the more esteemed kinds of hashish are prepared from this ganja. Ganja is met with in the Indian bazaars in dense bundles of 24 plants or heads apiece. The hashish in such extensive use in Central Asia is often seen in the bazaars of large cities in the form of cakes, 1 to 3 inches thick, 5 to 10 inches broad, and 10 to 15 inches long.

(3) *Charas*, or *churrus*, is the resin itself collected, as it exudes naturally from the plant, in different ways. The best sort is gathered by the hand like opium; sometimes the resinous exudation of the plant is made to stick first of all to cloths, or to the leather garments of men, or even to their skin, and is then removed by scraping, and afterwards consolidated by kneading, pressing, and rolling. It contains about one-third or one-fourth its weight of the resin. But the churrus prepared by different methods and in different countries differs greatly in appearance and purity. Sometimes it takes the form of egg-like masses of greyish-brown colour, having when of high quality a shining resinous

fracture. Often it occurs in the form of irregular friable lumps, like pieces of impure linseed oil-cake.

Hemp, however consumed, acts in a most strange way upon the nervous system, but its effects differ greatly with races as well as with individuals. Generally the first effect of a small dose is to produce increase of appetite and cheerfulness. Larger doses produce hallucinations, delirium, sleep, and sometimes catalepsy. During the dreamy state induced by an average dose of hashish, the patient becomes the sport of rapidly shifting ideas. Errors of perception as to time and place are a conspicuous characteristic of its effects on the mind. For the connexion of the name assasin with hashish, see vol. ii. p. 723.

Extract of hemp has been repeatedly tried in modern European medical practice without very consistent or satisfactory results. It has antispasmodic and anodyne characters, and has been employed in tetanus, spasmodic cough, hydrophobia, and some forms of mania. It is a quieter of the nervous system, but does not cause constipation, check the appetite, nor diminish the secretions like opium.

Hemp is very largely used in Eastern countries as an intoxicant and narcotic—probably by nearly 300 millions of the human race. The amount consumed cannot be estimated. Of dried hemp and churrus there was sent in 1876 not less than £86,000 worth through the Khyber Pass into British India.

There are three substances in the hemp-drug to which its activity has been attributed. Of these the resin, separated and investigated by Messrs T. & H. Smith, is the most abundant and probably the most important, and yet its chemical nature and properties are by no means certain. It is soluble in alcohol, and has a warm, bitter, acrid taste with a slight odour. It melts between 70° and 90° C., and has a pale brown colour. It is called *cannabin*. Cannabene is the volatile oil of Indian hemp obtained by distilling ganja or churrus with water. Its composition is represented by C_8H_{10} ; it boils between 235° and 240°. Cannabene is accompanied by a crystalline hydrocarbon containing 84 per cent. carbon and 16 per cent. hydrogen. The supposed occurrence of nicotine in Indian hemp has not been confirmed, and would not in any way suffice to explain the properties of the drug. Moreover, tobacco is often added to hemp. That there is a volatile alkaloid in hemp, though in small quantities, is, however, established beyond doubt. The proportion of pure resin in ganja was found by Messrs T. & H. Smith to be 6 or 7 per cent. Gastinel gives 3 per cent. as obtainable from Egyptian hemp. The volatile oil in fresh hemp probably does not exceed 3 parts in 1000. By treating the commercial resinous extract of Indian hemp with strong nitric acid, Bolas and Francis obtained (*Journ. Chem. Soc.*, vol. vii., n. a., p. 417) an oxidation product, soluble in alcohol and crystallizing in long flat prisms. The formula $C_8H_6O_2$ has been assigned to this substance, which is known as *oxycannabin*.

Hemp Seed, Cake, and Oil.—The ripe seeds, really fruits, being nuts or achenes of the hemp plant, contain about 34 per cent. of oil and 16 of albuminoids. When the crushed seeds have been submitted to pressure, the residual cake is found to retain about 7 per cent. of oil. The value of hemp cake as a cattle-food is lessened by its purgative property. The seeds are much used as a food for singing birds. A hundred parts of the seed yield from 70 to 75 of cake and 25 to 30 of oil. This oil has drying properties, though it is in this respect much inferior to linseed oil. Its specific gravity is .9307. The seeds are roundish ovate, about $\frac{1}{8}$ inch in length, and of a dark grey colour, with a pale ash-coloured network of surface-markings.

HEMS, HOMS, or HUMS, a town of Syria, about 63 miles by road north-east of Tripoli (Tarâbulus), situated 1312 feet, according to Černik, above the level of the sea, on the

eastern side of the valley of the Nahr el Asy or Orontes, which about 4 miles further down forms the lake of Hems, Atini, or Kabas. The *kala'at* or castle, a great mound "still crowned with a tiara of torn and ruined towers," forms a striking landmark well-known to the caravans journeying north from Damascus. It is about 120 feet in height, and has a breadth of 435 feet and a width of 375. According to Captain Burton, it probably occupies the site of the temple of the sun, which formed the glory of the ancient city: not only does it contain columnar masses of syenite, grey granite, and white marble, but he found, apparently in position, a Doric pilaster. Though the ancient walls of Hems, with a circuit of about a mile and a half, are greatly dilapidated and even in many places practically demolished, the town is entered by regular gates, six in number, which in olden times bore the names of the planets. Within it presents little except narrow and tortuous streets, poorly paved and foul, with houses for the most part of the meanest description; but none the less it is the seat of a Turkish vice-governor or mutesarif, as well as of a Greek and a Maronite bishop, and its cavalry barracks are capable of containing two regiments. As the market-town of the neighbouring tribes it has some commercial importance: it trades in cotton, sesame, and oil; and among its craftsmen it numbers a body of skilful goldsmiths and about 3000 silk weavers, whose looms produce the finest kind of kaffiehs or head-cloths. The population is estimated at from 20,000 to 40,000, and about 7000 are Christians. Jews are conspicuous by their absence, though one of the gates of the town in the quarter which they formerly occupied is still called the "Jews' Gate."

Hems is the Emesa, Emissa, or Hemesa of the Romans, and by Ptolemy it is assigned to the district of Apamee. Its inhabitants are mentioned among the early opponents of the Roman arms. Heliogabalus or Bassianus, declared emperor in 218 A. D., was a native of Emesa, and held office as a priest of the sun. It was in the neighbourhood of the town that the army of Zenobia was routed by Aurelian. The first Christian bishop is said to have been St Silvanus. About fourteen years after the Hegira Khalid bin Walid, who was to find his grave in one of its suburbs, made himself master of Hems; and from 1098 to 1187 it was in the hands of the crusaders. It was probably Saladin, by whom they were expelled, that turned the temple of the sun, which under Christian rule had been used as a cathedral, into the chief fortress of the place. In July 1831 Ibrahim Pasha, having defeated the governor of Aleppo at Hema, caused the fortress to be blown up.

The poet Ka'ab el Ahbâr is buried in the town, and the people show another grave which they wrongly believe to be that of Ja'afar el Tayyâr.

See Burton and Tyrwhitt Drake, *Unexplored Syria*, 1872.

HEMSTERHUIS, FRANÇOIS (1720-1790), writer on aesthetics and moral philosophy, was born at Franeker in Holland in 1720. He received an excellent education from his father, Tiberius Hemsterhuis, noticed below, and completed his studies at the university of Leyden. There undoubtedly he was attracted towards the study of the Platonic philosophy, which exercised the greatest influence both on the form and on the matter of his own writings. He did not, however, devote himself to a learned life after completing his university courses, but entered upon practical affairs, and for many years acted as secretary to the state council of the United Provinces. His interests were mainly philosophical, and partly by direct social intercourse with a few similarly disposed friends, partly by correspondence with philosophical writers of other countries, mainly with Jacobi, he preserved the continuity of his philosophical work. His writings, none of which can be described as of high speculative worth, are distinguished by elegance of form and by the touch of refined sentiment which is not uncommon among the amateur or dilettante philosophers of the 18th century. Any direct contributions to philosophy made by him are in the department of aesthetics or the general analysis of feeling. He died in 1790.

His first work, published in 1769, was a *Lettre sur la Sculpture*, written, like all the others, in French. It was followed in 1770 by the *Lettre sur les desirs*, in 1772 by the *Lettre sur l'homme et ses rapports*, in 1778 by *Sophyle*, a dialogue on the relation between soul and body, in 1779 by *Ariste*, a dialogue on the existence of the Divine Being, in 1787 by *Alexis ou l'âge d'or*, by *Simon, ou des facultés de l'âme*, and by the *Lettre de Dioclès à Diotime sur l'athéisme*. Collected editions of his works have been published in 1792 (2 vols.), and more completely by Meyboom, in 1846-50 (6 vols.). See Grucker, *François Hemsterhuis, sa Vie et ses Œuvres* (Paris, 1866).

HEMSTERHUIS, TIBERIUS (1685-1766), philologist and critic, was born on January 9, 1685, at Groningen in Holland. His father, a learned physician, recognizing the abilities of his son, gave him so good an early education that, when he entered the university of his native town in his fifteenth year, he speedily proved himself to be the best student of mathematics. After a year or two at Groningen, he was attracted to the university of Leyden by the fame of Perizonius; and while there he was entrusted with the flattering duty of arranging the manuscripts in the library. Though he accepted an appointment as professor of mathematics and philosophy at Amsterdam in his twentieth year, he had already directed his attention to the study of the ancient languages. In 1706 he completed the edition of Pollux's *Onomasticon* begun by Lederlin; but the praise he received from his countrymen was more than counterbalanced by two letters of criticism from Bentley, which mortified him so keenly that for two months he refused to open a Greek book. In 1717 Hemsterhuis was appointed professor of Greek at Franeker, but he did not enter on his duties there till 1720. In 1738 he became professor of national history also. Two years afterwards he was called to teach the same subjects at Leyden, where he died, April 7, 1766. Hemsterhuis deserves special note for reinstating the study of Greek in its honourable place among his fellow-countrymen, while he was also the founder of a laborious and useful Dutch school of criticism, of which Valckenaer, Lennep, and Ruhnken are the most famous disciples.

His chief writings are the following:—*Luciani Colloquia et Timon*, 1708; *Aristophanis Plutus*, 1744; *Nota, &c., ad Xenophontem Ephesium* in the *Miscellanea Critica* of Amsterdam, vols. iii. and iv.; *Observationes ad Chrysostomi Homilias; Orationes*, 1784; a Latin translation of the *Birds* of Aristophanes, in Kuster's edition; notes to Bernard's *Thomas Magister*, to Alberti's *Hesychius*, to Ernesti's *Callimachus*, and to Burmann's *Propertius*. See *Elogium T. Hemsterhusii* (with Bentley's letters) by Ruhnken, 1789; and *Supplementa Annotationis ad Elogium T. Hemsterhusii*, &c., Leyden, 1874.

HÉNAULT, CHARLES JEAN FRANÇOIS (1685-1770), French historian, was born in Paris 8th February 1685. His father, a farmer-general of taxes, was a man of literary tastes; and young Hénault obtained a good education at the Jesuit college and the Collège des Quatre-Nations. Captivated by the eloquence of Massillon, he in his fifteenth year entered the oratory with the view of becoming a preacher, but after two years' residence he changed his intention, and, inheriting a position which secured him access to the most select society of Paris, he at an early period achieved distinction by his gay, witty, and graceful manners, and by his literary talent as manifested in the composition of various light poetical pieces, and of two discourses which respectively gained a prize at the French Academy in 1707, and at the Académie des Jeux Floraux in 1708. In 1706 he became councillor of the parliament of Paris, and in 1710 he was chosen president of the court of *enquêtes*. He was admitted into the French Academy in 1723, and subsequently into the leading literary societies of Europe. After the death of Bernard de Conbert he became superintendent of the household of Queen Marie Leczinska, whose intimate friendship he had previously enjoyed. On his recovery in his fiftieth year from a dangerous malady, he professed to have undergone religious conversion and retired into private life, devoting

the remainder of his days to study and devotion. His devotion was, however, according to the Marquis d'Argenson "exempt from fanaticism, persecution, bitterness, and intrigue;" and it did not prevent him from continuing his friendship with Voltaire, to whom it is said he had formerly rendered the service of saving the manuscript of *La Henriade*, when its author was about to commit it to the flames. The literary work on which Hénault bestowed his chief attention was the *Abrégé Chronologique*, first published in 1744 without the author's name. It is a model of its kind, and is valuable both for popular use and as a work of reference. In the compass of two volumes he has comprised the whole history of France from the earliest times to the death of Louis XIV. His information is for the most part drawn from original sources, and for such a work the number of errors committed by Hénault was remarkably small. The results of deep researches and lengthened disquisitions on public law are summed up in a few words. The moral and political reflexions are always short and generally as fresh and pleasing as they are just. A few masterly strokes reproduce the leading features of each age and the characters of its illustrious men; accurate chronological tables set forth the most interesting events in the history of each sovereign and the names of the great men who flourished during his reign; and interspersed throughout the work are occasional chapters on the social and civil state of the country at the close of each era in its history. Continuations of the work have been made at separate periods by Fantin des Odeards, by Anguis with notes by Walckenaer, and by Michaud. Besides some other historical works of minor importance Hénault wrote several dramatic pieces of no particular merit. He died at Paris, 24th November 1770. His *Mémoires*, published in 1854, are somewhat fragmentary and disconnected, but contain many interesting anecdotes and details regarding persons of note.

See the *Correspondance* of Grimm, of Madame du Defauld, and of Voltaire; the notice by Walckenaer in the edition of the *Abrégé Chronologique*; and Sainte-Beuve, *Causeries du lundi*, vol. xi.

HENBANE (in French, *jusquiaume*, from the Greek *hyoscyamus*, or hog's-bean; in Italian, *giusquiamo*; and in German, *Schwarzes Bilienkraut*, *Hühnertod*, *Saubohne*, and *Zigeuner-Korn* or "gipsies' corn") is the common name of the *Hyoscyamus niger*, a Solanaceous plant indigenous to Britain, found wild in waste places, on rubbish about villages and old castles, and cultivated for medical use at Mitcham and other places in Surrey, and in Bedfordshire, Cambridgeshire, and Hereford. It occurs also in central and southern Europe and in western Asia, and has long been naturalized in the United States. There are two forms of the plant, an annual and a biennial, which spring indifferently from the same crop of seed,—the one growing on during summer to a height of from 1 to 2 feet, and flowering and perfecting seed; the other producing the first season only a tuft of radical leaves, which disappear in winter, leaving underground a thick fleshy root, from the crown of which arises in spring a branched flowering stem, usually much taller and more vigorous than the flowering stems of the annual plants. The biennial form is that which is considered officinal. The radical leaves of this biennial plant spread out flat on all sides from the crown of the root; they are ovate-oblong, acute, stalked, and more or less incised-toothed, of a greyish-green colour, and covered with viscid hairs; these leaves perish at the approach of winter. The flowering stem pushes up from the root-crown in spring, ultimately reaching from 3 to 4 feet in height, and as it grows becoming branched, and furnished with alternate sessile leaves, which are stem-clasping, oblong, unequally-lobed, clothed with glandular clammy hairs, and of a dull grey-green, the whole plant having a powerful nauseous

odour. The flowers are shortly-stalked, the lower ones growing in the fork of the branches, the upper ones sessile in one-sided leafy spikes which are rolled back at the top before flowering, the leaves becoming smaller upwards and taking the place of bracts. The flowers have an urceolate calyx which persists around the fruit and is strongly veined, with five stiff, broad, almost prickly lobes; these, when the soft matter is removed by maceration, form very elegant specimens when associated with leaves prepared in a similar way. The corollas are obliquely funnel-shaped, of a dirty yellow or buff, marked with a close reticulation of purple veins. The capsule opens transversely by a convex lid, and contains numerous seeds. Both the leaves and the seeds are employed in pharmacy. The Mahometan doctors of India are accustomed to prescribe the seeds. Henbane yields a poisonous alkaloid, *hyoscyamine*, which is stated to have properties almost identical with those of atropine, from which it differs in being more soluble in water. It is usually obtained in an amorphous, scarcely ever in a crystalline state. Its properties have been investigated in Germany by Husemann, Schroff, Höhn, &c. Höhn finds its chemical composition expressed by $C_{13}H_{23}N_2O_3$. (Compare Hellmann, *Beiträge zur Kenntniss der physiolog. Wirkung des Hyoscyamins*, &c., Jena, 1874.) In small and repeated doses henbane has been found to have a tranquillizing effect upon persons affected by severe nervous irritability. In poisonous doses it causes loss of speech, distortion, and paralysis. In the form of extract or tincture it is a valuable remedy in the hands of a medical man, either as an anodyne, a hypnotic, or a sedative. The extract of henbane is rich in nitrate of potassium and other inorganic salts. The smoking of the seeds and capsules of henbane is noted in books as a somewhat dangerous remedy adopted by country people for toothache. Accidental poisoning from henbane occasionally occurs, owing sometimes to the apparent edibility and wholesomeness of the root.

HENDERSON, ALEXANDER (1583–1646), a celebrated Scottish ecclesiastic, was born in 1583. He was educated at the university of St Andrews, where he was appointed professor of rhetoric and philosophy and questor of the faculty of arts in 1610. A year or two after this he was presented to the living of Leuchars by Archbishop Gladstones. As Henderson was forced upon his parish by an archbishop, and as he was known to sympathize with Episcopacy, his settlement was at first extremely unpopular; but he subsequently changed his views, and became a Presbyterian in doctrine and church government, and one of the most esteemed ministers in Scotland. He early made his mark as a church leader, and took an active part in petitioning against Episcopal innovations. On the 1st of March 1638 the public signing of the "National Covenant" began in Greyfriars Church, Edinburgh. Henderson is mainly responsible for this document; and he seems always to have been applied to when any manifestations of unusual ability was required. In July of the same year he proceeded to the north, to debate on the "Covenant" with the famous Aberdeen doctors; but he was not well received by them. "The voyd church was made fast, and the keys kepted by the magistrate," says Baillie. Henderson's next public appearance was in the famous Assembly which met in Glasgow on the 21st of November 1638. He was chosen moderator by acclamation, being, as Baillie says, "incomparable the ablest man of us all for all things." The marquis of Hamilton was the king's commissioner; and, when the Assembly insisted on proceeding with the trial of the bishops, he formally dissolved the meeting under pain of treason. Nothing daunted, however, they sat till the 20th of December, deposed all the Scottish bishops, excommunicated a number of them, repealed all acts

favouring Episcopacy, and reconstituted the Scottish Kirk on thorough Presbyterian principles. During the sitting of this Assembly it was carried by a majority of seventy-five votes that Henderson should be transferred to Edinburgh. He had been at Leuchars for about twenty-three years, and was extremely reluctant to leave it. While Scotland and England were preparing for the "First Bishops' War," Henderson drew up two papers, entitled respectively—*The Remonstrance of the Nobility*, and *Instructions for Defensive Arms*. The first of these documents he published himself; the second was published against his wish by Corbet, a deposed minister. The "First Bishops' War" did not last long. At the Pacification of Birks the king had virtually to grant all the demands of the Scots. In the negotiations for peace Henderson was one of the Scottish commissioners, and made a very favourable impression on the king. In 1640 Henderson was elected by the town council rector of Edinburgh university—an office to which he was annually re-elected till his death. The Pacification of Birks had been wrung from the king; and the Scots, seeing that he was preparing for the "Second Bishops' War," took the initiative, and pressed into England so vigorously that Charles had again to yield everything. The maturing of the treaty of peace took a considerable time; and Henderson was again active in the negotiations, first at Ripon, and afterwards at London. While he was in London he had a personal interview with the king, with the view of obtaining assistance for Edinburgh university from the money formerly applied to the support of the bishops. On Henderson's return to Edinburgh in July 1641, the Assembly was sitting at St Andrews. To suit the convenience of the parliament, however, it removed to Edinburgh; and Henderson was elected moderator of the Edinburgh meeting. In this Assembly he proposed that "a confession of faith, a catechism, a directory for all the parts of the public worship, and a platform of government, wherein possibly England and we might agree," should be drawn up. This was unanimously approved of, and the laborious undertaking was left in Henderson's hands; but the "notable motion" did not lead to any immediate results. During Charles's second state-visit to Scotland, in the autumn of 1641, Henderson acted as his chaplain, and managed to get the funds, formerly belonging to the bishopric of Edinburgh, applied to the metropolitan university. In 1642 Henderson was engaged in corresponding with England on ecclesiastical topics; and, shortly afterwards, he went to Oxford to mediate between the king and his parliament; but his mission proved a failure. A memorable meeting of the General Assembly was held in August 1643. Henderson was elected moderator for the third time. He presented a draft of the famous "Solemn League and Covenant," which was received with great enthusiasm. Unlike the "National Covenant" of 1638, which applied to Scotland only, this document was common to the two kingdoms. Henderson, Baillie, Rutherford, and others were sent up to London to represent Scotland in the Assembly at Westminster. The "Solemn League and Covenant," after undergoing some slight alterations, passed the two Houses of Parliament and the Westminster Assembly, and thus became law for the two kingdoms. By means of it Henderson has had an extraordinary influence on the history of Great Britain. As Scottish commissioner to the Westminster Assembly, he was in England from August 1643 till August 1646; and the action of the Scottish commissioners gave a fresh impetus to English Presbyterianism. Early in 1645 Henderson was sent to Uxbridge to aid the commissioners of the two parliaments in negotiating with the king; but nothing came of the conference. In 1646 the king joined the Scottish army; and, after retiring with them to New-

castie, he sent for Henderson, and discussed with him the two systems of church government in a number of papers. Meawhile Henderson was failing in health. He sailed to Scotland, and eight days after his arrival died on the 19th of August 1646. He was buried in Greyfriars Churchyard, Edinburgh; and his death was the occasion of national mourning in Scotland. An absurd story was at once invented to the effect that, after recanting to the king's views, he had died of remorse. A document was forged, purporting to be a "Declaration of Mr Alexander Henderson;" and, although this paper was disowned, denounced, and shown to be false in the General Assembly of August 1648, the fiction was used by Clarendon, and still finds a place in professedly historical compilations.

Henderson is one of the greatest men in the history of Scotland, and, next to Knox, is certainly the most famous of Scottish ecclesiastics. He had great political genius; and his statesmanship was so influential that "he was," as Professor Masson well observes, "a cabinet minister without office." He has made a deep mark on the history, not only of Scotland, but of England; and the existing Presbyterian Churches in Scotland are largely indebted to him for the forms of their dogmas and their ecclesiastical organization. He is thus justly considered the second founder of the Reformed Church in Scotland.

For further information about Henderson reference may be made to M'Crie's *Life of Alexander Henderson*, 1846; Aiton's *Life and Times of Alexander Henderson*, 1836; *The Letters and Journals of Robert Baillie*, 1841-2 (an exceedingly valuable work, from an historical point of view); Burton's *History of Scotland*; Masson's *Life of Drummond of Hawthornden*; and, above all, Masson's *Life of Milton*. (T. G.)

HENDERSON, EBENEZER, Scottish dissenting minister and theological and miscellaneous writer, was born at the Linn near Dunfermline, November 17, 1784, and died at Mortlake, May 17, 1858. He was the youngest son of an agricultural labourer, and after three years' schooling spent some time at watchmaking and as a shoemaker's apprentice. In 1803 he joined Mr Robert Haldane's theological seminary, and in 1805 was selected to accompany the Rev. John (afterwards Dr) Paterson to India; but as the East India Company would not allow British vessels to convey missionaries to India, Henderson and his colleague went to Denmark to await the chance of a passage to Serampore. Being unexpectedly delayed, they ultimately decided to settle in Denmark, and in 1806 Henderson was fixed at Elsinore. From this time till about 1817 he was engaged in encouraging the distribution of Bibles in the Scandinavian countries, and in the course of his labours he visited Sweden and Lapland (1807-8), Iceland (1814-15), and the mainland of Denmark and part of Germany (1816). During most of this time he was an agent of the British and Foreign Bible Society. In 1818, after a visit to England, he travelled in company with Dr Paterson through Russia as far south as Tiflis, but, instead of settling as was proposed at Astrakhan, he had to retrace his steps, having resigned his connexion with the Bible Society. In 1822 he was invited by Prince Alexander Galitzin to assist the Russian Bible Society in translating the Scriptures into various languages spoken in the Russian empire. After twenty years of foreign labour Henderson returned to England, and in 1825 was appointed tutor of the Mission College, Gosport. In 1830 he succeeded Dr William Harrison as theological lecturer and professor of Oriental languages in Highbury Congregational College, and though in 1850, on the amalgamation of the colleges of Homerton, Coward, and Highbury, he was excluded from office through age, he was pastor in 1852-53 of a chapel at Mortlake. His last work was a translation of the book of Ezekiel. Henderson was a man of great linguistic attainment: in the course of his

labours he made himself more or less acquainted, not only with the ordinary languages of scholarly accomplishment and the various members of the Scandinavian group, but also with Hebrew, Syriac, Ethiopic, Russian, Arabic, Tatar, Persian, Turkish, Armenian, Manchoo, Mongolian, and Coptic. He organized the first Bible Society in Denmark (1814), and paved the way for several others. In 1817 he was nominated by the Scandinavian Literary Society a corresponding member; and in 1840 he was made D.D. by the university of Copenhagen. He was honorary secretary for life of the Religious Tract Society, and one of the first promoters of the British Society for the Propagation of the Gospel among the Jews. The records of his travels in Iceland (1818) were valuable contributions to our knowledge of that island. His other principal works are *Biblical Researches and Travels in Russia* (1826), *Divine Inspiration* (1836), and annotated translations of Isaiah (1840, 1857), the twelve minor prophets (1845), and Jeremiah (1851).

See *Memoirs of Ebenezer Henderson*, by Thulia S. Henderson (his daughter), London, 1859.

HENGSTENBERG, ERNST WILHELM (1802-1869), for more than forty years one of the most conspicuous and able champions of the strictest Lutheran orthodoxy, was born at Fröndenber, a Westphalian village near Hamm and not far from the Ruhr, on October 20, 1802; received his entire school education under the roof of his father, who was a minister of the Reformed Church, and head of the Fröndenber Fräuleinstift; and entered the university of Bonn in 1819, shortly before the completion of his seventeenth year. There he attended the lectures of Freytag and Gieseler on Old Testament exegesis and church history, but his energies were principally devoted to philosophy and philology, and his earliest publication was an edition of the *Moallakah* of Amru' l' Kais (*Amrukeisi Moallakah cum scholiis Zuzenii editit, latine vertit, et illustravit E. G. H.*, 1823), which gained for him the prize at his graduation in the philosophical faculty, and the public commendation of Sylvestre de Sacy. This was followed in 1824 by a German translation of Aristotle's *Metaphysica*. On quitting Bonn it had been Hengstenberg's wish to complete his theological studies under Neander and Tholuck in Berlin; but finding himself without the means of doing so, he accepted for a year a situation at Basel as tutor in Oriental languages to J. J. Stähelin. Then it was that, suffering much from ill-health and deeply mourning the loss of his mother, he began to direct his attention, with an ardour formerly unknown to him, to the spiritual truths of the Bible. His studies and experiences at this crisis resulted in a conviction, never afterwards shaken, not only of the divine character of evangelical religion, but also of the unapproachable adequacy of its expression in the Augsburg Confession. Taking as his motto Psalm cxviii. 17, he resolved thenceforward to devote himself to the uncompromising defence of that creed. In the autumn of 1824 he joined the philosophical faculty of Berlin as a privat-docent, and in the following year he became a licentiate in theology, his theses even then being remarkable for their evangelical fervour and for their emphatic protest against every form of "rationalism," especially in questions of Old Testament criticism. In 1826 he became professor extraordinarius in theology; and in July 1827 appeared under Hengstenberg's editorship the first number of the *Evangelische Kirchenzeitung*, a "reactionary" journal which in his hands was destined to acquire an almost unique reputation as an organ of religious, theological, and ecclesiastical controversy. It did not, however, attain to great notoriety until in 1830 an anonymous article (by E. L. von Gerlach) appeared, which openly charged Professors Gesenius and Wegscheider with infidelity and profanity, and on the ground of these accusations advo-

cated the interposition of the civil power, thus giving rise to the prolonged "Hallische Streit" as it was called, which was at least effectual in giving the public a due impression of the energy and zeal of the new "evangelical" school. In 1828 the first volume of Hengstenberg's *Christologie des Alten Testaments* passed through the press; in the autumn of that year he was promoted to the dignity of professor ordinarius in theology; and in 1829 he married. The remainder of his life, apart from the excitement which its various literary activities imparted to it, was uneventful. He died on the 28th of May 1869.

The following is a list of the principal works of Hengstenberg:—*Christologie des Alten Testaments* (1829-35; 2d ed., 1854-57; Eng. transl. by R. Keith, 1835-39, also in Clark's "Foreign Theological Library," by Th. Meyer and J. Martin, 1854-58), a work of much ingenuity and considerable learning, but which will be differently valued according to the hermeneutical principles of the individual critic; *Beiträge zur Einleitung in das Alte Testament* (1831-39; Engl. transl., "Dissertations on the Genuineness of Daniel and the Integrity of Zechariah," Edin., 1848, and "Dissertations on the Genuineness of the Pentateuch," Edin., 1847), in which the traditional view on each question is strongly upheld, and much capital is made of the absence of harmony among the negative critics; *Die Bücher Moses und Ägypten* (1841), spoken of by Diestel as "perhaps Hengstenberg's most meritorious work;" *Die Geschichte Bileams u. seiner Weissagungen* (1842; translated into English along with the Dissertations on Daniel and Zechariah mentioned above); *Commentar über die Psalmen* (1842-45; 2d ed. 1849-52; Eng. transl. by Fairbairn and Thomson, Edin., 1844-48), which shares the merits and defects of the *Christologie*; *Die Offenbarung Johannis erläutert* (1841-51; 2d ed. 1861-62; Eng. transl. by Fairbairn, also in Clark's "Foreign Theological Library," 1851-52); *Das Hohe Lied ausgelegt* (1853); *Der Prediger Salomo ausgelegt* (1859); *Das Evangelium Johannis erläutert* (1861-63; 2d ed. 1867-71; Eng. transl. 1865), and *Die Weissagungen des Propheten Ezechiel erläutert* (1867-68). Of minor importance are *De rebus Tyrriorum commentatio academica* (1832); *Ueber den Tag des Herrn* (1852); *Das Passa, ein Vortrag* (1853); and *Die Opfer der heiligen Schrift* (1859). Several series of papers also, as, for example, on "The Retention of the Apocrypha," "Freemasonry," "Duelling," and "The Relation between the Jews and the Christian church," which originally appeared in the *Kirchenzeitung*, were afterwards printed in a separate form. *Geschichte des Reiches Gottes unter dem Alten Bunde* (1869-70), *Das Buch Hiob erläutert* (1870-75), and *Vorlesungen über die Leidensgeschichte* (1875) were published, from Hengstenberg's papers, posthumously. See Bachmann's *Ernst Wilhelm Hengstenberg* (1876-79); also his article in Herzog and Plitt's *Encyclopädie* (1879).

HENKE, HEINRICH PHILIPP KONRAD (1752-1809), a learned German theologian of the broad school, best known as a writer on church history, was born at Hehlen, Brunswick, on July 3, 1752, was educated at the gymnasium of Brunswick and the university of Helmstädt, and from 1778 until his death, which occurred on May 2, 1809, held a professorship of theology in that university. His principal work (*Kirchengeschichte*, in 6 vols., 1788-1804; 2d ed. 1795-1806) is commended by Baur for fulness, accuracy, and artistic composition, as one of the best in that class of literature. His other works are *Lineamenta institutionum fidei Christianæ historico-criticarum* (1783), *Opuscula Academica* (1802), and two volumes of *Predigten*. His son, Ernst Ludwig Theodor (1804-1872), has also left a name in the literature of theology and ecclesiastical history, having been the author of monographs upon *Georg Calixt u. seine Zeit* (1853-60), *Papst Pius VII.* (1860), *Konrad von Marburg* (1861), *Kaspar Peucer u. Nik. Krell* (1865), *Jak. Friedr. Fries* (1867), as well as of other works.

HENLEY, JOHN (1692-1759), an eccentric clergyman of the last century, commonly known as "Orator Henley," was born August 3, 1692, at Melton-Mowbray, where his father was vicar. After attending the grammar schools of Melton and Oakham, he in his seventeenth year entered St John's College, Cambridge, and while still an undergraduate he addressed in February 1712, under the pseudonym of Peter de Quir, a letter to the *Spectator* displaying no small wit and humour. After graduating B.A. he became assistant and then head-master of the

grammar school of his native town, uniting to these duties those also of assistant curate. His superabundant energy was not, however, fully consumed by this plurality of offices, for besides publishing in 1714 a poem entitled *Esther, Queen of Persia*, containing many vigorous and eloquent passages, he also devoted his attention to the compilation of a grammar of ten languages entitled *The Complete Linguist* (2 vols., London, 1719-21). In his school he is said to have introduced many new methods of study, but whether it was that his innovations were not sufficiently appreciated, or that he desired a wider sphere for the exercise of his exceptional abilities, he resolved to place his services at the disposal of the metropolis, where he arrived with thirty recommendatory letters from some of the most influential persons of his native county. He succeeded in obtaining the appointment of assistant preacher in the chapels of Ormond Street and Bloomsbury, and in 1723 was presented to the rectory of Chelmondiston in Suffolk; but residence being insisted on, he resigned both his appointments, and on July 3, 1726, opened what he called an "oratory" in Newport Market, which he licensed under the Toleration Act. Into his services he introduced many peculiar alterations: he drew up a "Primitive Liturgy," in which he substituted for the Nicene and Athanasian creeds two creeds taken from the apostolical constitutions; for his "Primitive Eucharist" he made use of unleavened bread and mixed wine; he distributed at the price of one shilling medals of admission to his oratory, with the device of a sun rising to the meridian, with the motto *Ad summa*, and the words *Inveniam viam aut faciam* below. But the most original element in the services was Henley himself, who is described by Pope in the *Dunciad* as

"Preacher at once and zany of his age."

He possessed some oratorical ability and adopted a very theatrical style of elocution, "tuning his voice and balancing his hands;" and his addresses were a strange medley of solemnity and buffoonery, of clever wit and the wildest absurdity, of able and original disquisition and the worst artifices of the oratorical charlatan. His services were much frequented by the "freethinkers," and he himself expressed his determination "to die a rational." Besides his sermons on Sunday he delivered on Wednesday lectures chiefly on social and political subjects; and he also projected a scheme for connecting with the "oratory" a university on quite a novel plan, and intended to be, in a sense too utopian to be realized, the foster-mother of the arts and sciences. For some time he edited the *Hyp Doctor*, a weekly paper established in opposition to the *Craftsman*, and for this service he enjoyed a pension of £100 a year from Sir Robert Walpole. At first the orations of Henley drew great crowds, but, although he never discontinued his services, his audience latterly dwindled almost entirely away. He died 13th October 1759.

Henley is the subject of several of Hogarth's prints. His life, professedly written by A. Welsted, but in all probability by himself, was inserted by him in his *Oratorical Transactions*. See Nichol's *History of Leicestershire*, and Disraeli's *Calamities of Authors*.

HENLEY-ON-THAMES, a market-town of Oxfordshire, England, is situated on the left bank of the Thames and at the terminus of a branch of the Great Western Railway. It is 22 miles S. of Oxford and 35 W. from London by rail, and 47 miles from Oxford and 64½ from London by the river. It occupies one of the most beautiful situations on the Thames, at the foot of the finely wooded Chiltern Hills. The river is crossed by an elegant stone bridge of five arches, constructed in 1786 at a cost of £10,000. The principal buildings are the parish church, a handsome Gothic structure recently restored at a cost of over £7000, possessing a lofty tower of intermingled flint and stone, which is attributed to Cardinal Welsey, but which was more pro-

bably erected by Bishop Longland; the grammar school, founded in 1605; the town-hall, a neat building supported by Doric columns; the reading-room and library, and various charitable institutions. Henley is a favourite summer resort, and also possesses some trade in corn, flour, malt, and timber. It is celebrated for the Henley Royal Regatta, the principal gathering of amateur oarsmen in England, which usually takes place in July. The population of the parish in 1871 was 3736, and of the local board district 4623.

Henley existed at a very early period, and according to some authorities was a Roman station. It obtained a charter of incorporation from Elizabeth, in which it is named *Hanleygang* or *Hanneburg*. In 1643 it was occupied by the Parliamentary forces, who successfully repelled an attack made upon them by the Royalists.

See *History of Henley-on-Thames*, by John Southerden Burns, London, 1861, and *An Account of the Races at the Annual Henley Regattas from their commencement June 1839 to the year 1879*, Henley, 1879.

HENNA is the Persian name for a small shrub found in the East Indies, Persia, the Levant, and along the African coasts of the Mediterranean, where it is frequently cultivated. It is the *Lawsonia alba* of botanists, and from the fact that young trees are spineless, while older ones have the branchlets hardened into spines, it has also received the names of *Lawsonia inermis* and *L. spinosa*. It forms a slender shrubby plant of from 8 to 10 feet high, furnished with opposite oval-lance-shaped smooth leaves, which are entire at the margins, and bears small white four-petalled sweet-scented flowers disposed in panicles. The four spreading petals are obovate, and furnished with claws; and alternating with them are eight stamens approximating by pairs. Its Egyptian name is *Khenna*, its Arabic name *Al Khanna*, its Indian name *Mende*, while in England it is called *Egyptian privet*, and in the West Indies, where it is naturalized, *Jamaica mignonette*.

Henna or Henné is of ancient repute as a cosmetic. This consists of the leaves of the *Lawsonia* powdered and made up into a paste; this is employed by the Egyptian women, and also by the Mahometan women in India, to dye their finger nails and other parts of their hands and feet of an orange-red colour, which is considered to add to their beauty. The colour lasts for three or four weeks, when it requires to be renewed. It is moreover used for dyeing the hair and beard, and even the manes of horses; and the same material is employed for dyeing skins and morocco-leather a reddish-yellow, but it contains no tannin. The practice of dyeing the nails was common amongst the Egyptians, and not to conform to it would have been considered indecent. It has descended from very remote ages, as is proved by the evidence afforded by Egyptian mummies, the nails of which are most commonly stained of a reddish hue. Henna is also said to have been held in repute amongst the Hebrews, being considered to be the plant referred to as camphire in the Bible (Song of Solomon i. 14; iv. 13). "The custom of dyeing the nails and palms of the hands and soles of the feet of an iron-rust colour with henna," observes Dr Royle, "exists throughout the East from the Mediterranean to the Ganges, as well as in Northern Africa. In some parts the practice is not confined to women and children, but is also followed by men, especially in Persia. In dyeing the beard, the hair is turned to red by this application, which is then changed to black by a preparation of indigo. In dyeing the hair of children, and the tails and manes of horses and asses, the process is allowed to stop at the red colour which the henna produces." Mahomet, it is said, used henna as a dye for his beard, and the fashion was adopted by the caliphs. "The use of henna," remarks Lady Callcott in her *Scripture Herbal*, "is scarcely to be called a caprice in the East.

There is a quality in the drug which gently restrains perspiration in the hands and feet, and produces an agreeable coolness equally conducive to health and comfort." She further suggests that if the Jewish women were not in the habit of using this dye before the time of Solomon, it might probably have been introduced amongst them by his wife, the daughter of Pharaoh, and traces to this probability the allusion to "camphire" in the passages in Canticles above referred to.

The preparation of henna consists in reducing the leaves and young twigs to a fine powder, catechu or Incense leaves in a pulverized state being sometimes mixed with them. When required for use, the powder is made into a pasty mass with hot water, and is then spread upon the part to be dyed, where it is generally allowed to remain for one night.

It has been already noted that the flowers of the *Lawsonia* are very fragrant, whence they derive in the West Indies the name of Jamaica mignonette. According to Lady Callcott, they are often used by the eastern women to adorn their hair; and Mr Simmonds states that the distilled water from the flowers is used as a perfume. The plant is further credited with the possession of vulnerary and astringent properties.

HENNEBONT, a town of France, arrondissement of Lorient, and department of Morbihan, is situated on the Blavet, not far from its mouth, and 25 miles W.N.W. of Vannes. It is a picturesque old town, and contains some remains of its former fortifications. The church of Notre Dame de Paradis, a beautiful building of the 16th century, possesses some fine wood carving. The town has an important corn-market, and considerable shipping trade in iron, corn, honey, wax, hemp, cider, and wine. Shipbuilding, sawing, and tanning are also carried on. Hennebont is famed for the resistance which it made, under the widow of John de Montfort, when besieged by the armies of Philip of Valois and Charles of Blois. The population in 1876 was 4844.

HENNEQUIN, PHILIPPE AUGUSTE (1763-1833), French painter, was a pupil of David. He was born at Lyons in 1763, distinguished himself early by winning the "grand prix," and left France for Italy. The disturbances at Rome, during the course of the Revolution, obliged him to return to Paris, where he executed the Federation of the 14th of July, and visiting his native town was at work there on a large design commissioned for the town-hall, when in July 1794 he was accused before the revolutionary tribunal and thrown into prison. Hennequin escaped, only to be anew accused and imprisoned in Paris, and after running great danger of death, seems to have devoted himself thenceforth wholly to his profession. At Paris he finished the picture ordered for the municipality of Lyons, and in 1801 produced his chief work, *Orestes pursued by the Furies* (Louvre, engraved by Landon, *Annales du Musée*, vol. i. p. 105). He was one of the four painters who competed when in 1802 Gros carried off the official prize for a picture of the Battle of Nazareth, and in 1808 Napoleon himself ordered Hennequin to illustrate a series of scenes from his German campaigns, and commanded that his picture of the Death of General Salomon should be engraved. After 1815 Hennequin retired to Liège, and there, aided by subventions from the Government, carried out a large historical picture of the Death of the Three Hundred in defence of Liège—a sketch of which he himself engraved. In 1824 Hennequin settled at Tournay, and became director of the academy; he exhibited various works at Lille in the following year, and continued to produce actively up to the day of his death, which took place in May 1833. The *Orestes* of the Louvre is his capital work; it shows a certain style and finish of draughtsmanship, but the attitudes are melodramatic, the composition stagy, and the colour false and violent.

HENNERSDORF, or **SEIPHENNERSDORF**, a manufacturing village of Saxony, in the circle of Bautzen, and 20 miles S.S.E. of the town of that name. The inhabitants are engaged in weaving and bleaching, and in the manufacture of woollen goods, satin, arnotta, machinery, bricks, and wooden shoes. There is also an iron foundry. Population (1875), 6366.

HENRIETTA MARIA (1609-1666), queen of Charles I. of England, born November 25, 1609, was the daughter of Henry IV. of France. When the first overtures for her hand were made on behalf of Charles, prince of Wales, in the spring of 1624, she was little more than fourteen years of age. Her brother, Louis XIII., only consented to the marriage on the condition that the English Roman Catholics were relieved from the operation of the penal laws. When therefore she set out for her new home in June 1625, she had already pledged the husband to whom she had been married by proxy on May 1 to a course of action which was certain to bring unpopularity on him as well as upon herself.

That husband was now king of England. The early years of the married life of Charles I. were most unhappy. He soon found an excuse for breaking his promise to relieve the English Catholics. His young wife was deeply offended by treatment which she naturally regarded as unhandsome. The favourite Buckingham stirred the flames of his master's discontent. Charles in vain strove to reduce her to tame submission. After the assassination of Buckingham in 1628 the barrier between the married pair was broken down, and the bond of affection which from that moment united them was never loosened.

For some years Henrietta Maria's chief interests lay in her young family, and in the amusements of a gay and brilliant court. She loved to be present at dramatic entertainments, and her participation in the private rehearsals of the *Shepherd's Pastoral*, written by her favourite Walter Montague, probably drew down upon her the savage attack of Prynne. With political matters she hardly meddled as yet. Even her co-religionists found little aid from her till the summer of 1637. She had then recently opened a diplomatic communication with the see of Rome. She appointed an agent to reside at Rome, and a papal agent, a Scotchman named Con, accredited to her, was soon engaged in effecting conversions amongst the English gentry and nobility. Henrietta Maria was well pleased to become a patroness of so holy a work, especially as she was not asked to take any personal trouble in the matter. Protestant England took alarm at the proceedings of a queen who associated herself so closely with the doings of "the grim wolf with privy paw."

When the Scottish troubles broke out, she raised money from her fellow Catholics to support the king's army on the borders in 1639. During the session of the Short Parliament in the spring of 1640, the queen urged the king to oppose himself to the House of Commons in defence of the Catholics. When the Long Parliament met, the Catholics were believed to be the authors and agents of every arbitrary scheme which was supposed to have entered into the plans of Strafford or Laud. Before the Long Parliament had sat for two months, the queen was urging upon the pope the duty of lending money to enable her to restore her husband's authority. She threw herself heart and soul into the schemes for rescuing Strafford and coercing the parliament. The army plot, the scheme for using Scotland against England, and the attempt upon the five members were the fruits of her political activity.

In the next year the queen effected her passage to the Continent. In February 1643 she landed at Burlingtoa Quay, placed herself at the head of a force of loyalists, and marched through England to join the king near Oxford. After little more than a year's residence there, on April

3, 1644, she left her husband to see his face no more. At Exeter she gave birth to her youngest child, who was one day to be duchess of Orleans, and to negotiate the treaty of Dover. Henrietta Maria found a refuge in France. Richelieu was dead, and Anne of Austria was compassionate. As long as her husband was alive the queen never ceased to encourage him to resistance.

During her exile in France she had much to suffer. Her husband's execution in 1649 was a terrible blow. She brought up her youngest child Henrietta in her own faith, but her efforts to induce her youngest son, the duke of Gloucester, to take the same course only produced discomfort in the exiled family. The story of her marriage with her attached servant Lord Jermyn needs more confirmation than it has yet received to be accepted, but all the information which has reached us of her relations with her children points to the estrangement which had grown up between them. When after the Restoration she returned to England, she found that she had no place in the new world. She received from parliament a grant of £30,000 a year in compensation for the loss of her dower-lands, and the king added a similar sum as a pension for himself. In January 1661 she returned to France to be present at the marriage of her daughter Henrietta to the duke of Orleans. In July 1662 she set out again for England, and took up her residence once more at Somerset House. Her health failed her, and on June 24, 1665, she departed in search of the clearer air of her native country. She died on August 31, 1666, at Colombe, not far from Paris.

HENRY I. (1068-1135), king of England, fourth and youngest son of William the Conqueror and Matilda of Flanders, was born some time in the autumn of 1068. Local tradition fixes his birthplace at Selby in Yorkshire. Little is known of his earlier life, except that he received an unusually good education, and attained a proficiency rare among the princes of his day. In 1086 he was dubbed knight. Next year his father bequeathed to him on his death-bed a sum of five thousand pounds, and is said to have foretold that he would eventually be king. Condemned, by the division of the Conqueror's territories, to a position of inferiority to his two brothers, he used his legacy to improve that position. Robert, being in need of money, sold him the districts of the Côtentin and the Avrachin, which he held of his brother as a fief. His relations with Robert were not always friendly, but he defended Normandy against Rufus, and aided his liege lord in putting down a revolt in Rouen. Nevertheless, in the treaty between William and Robert made in 1091, he was excluded from the succession, and soon afterwards was deprived of his lands in Normandy.

The treatment he met with from Robert was not likely to make him support the terms of the treaty of 1091. Immediately after the death of Rufus, he rode to Winchester, and seized the royal hoard in that city. Next day (August 3, 1101) he was elected king by such of the witan as were present, and on Sunday, August 5th, he was crowned at Westminster. In order to conciliate the clergy and the nation, he recalled Anselm, imprisoned Ranulf Flambard, and issued a comprehensive charter of liberties. Before the year was out he married Matilda, daughter of Malcolm and Margaret, and great-granddaughter of Edmund Ironside, a step which greatly strengthened his otherwise insecure title to the crown. The alliance thus contracted with the church and the nation was his constant support in the struggle with his brother and his unruly vassals, which began immediately. It resulted in the conquest of Normandy, the temporary suppression of feudalism, and the consolidation of royal power on both sides of the Channel. Robert, as soon as he returned from the Holy Land, attempted with the aid of a conspiracy in

England to wrest the crown from the usurper. He landed at Portsmouth (August 1, 1101), but before a blow was struck the brothers came to terms. Robert recognized Henry as king of England, and returned to Normandy. Henry's vengeance fell upon his brother's partisans, and Robert of Belesme and several others were banished from the country and lost their English estates. Secure in England, Henry carried the war into the enemy's country. His brother's misgovernment gave him both pretext and opportunity. After two or three expeditions, the struggle was brought to a close by the battle of Tenchebrai (September 28, 1106), in which Robert was taken prisoner. He remained in captivity till his death in 1134, and Normandy passed into the possession of the English king. This conquest at once brought Henry into collision with France. Louis the Fat was a constant supporter of Henry's rebellious vassals, and of his rival and nephew, William, son of Robert. Henceforward Henry had to spend most of his time in the duchy. A war with France (1111-1113) ended in a peace which brought some advantages to Henry. Louis gave up his claim to the sovereignty of Maine and Brittany, and Henry was able to carry his old opponent, Robert of Belesme, to England, where he was imprisoned for the rest of his life. Henry had already, though in vain, attempted to secure the aid of Flanders by two treaties with Count Robert (1103, 1108). He now sought a mightier ally in the emperor Henry V., to whom he married his daughter Matilda (January 7, 1114). Another war with France, which broke out in 1116, and in which Louis took up the cause of William, son of Robert, against his uncle, was marked by the battle of Noyon (1119). At a council at Rheims (1119) Louis accused Henry before Pope Calixtus of rebellion and usurpation. Henry, however, pleaded his own cause before the pope at Gisors so persuasively that Calixtus brought about a peace between the two kings (1120) on the basis of a mutual restoration of conquests. During the war Henry had suffered a severe loss in the death of his queen Matilda. He now felt it more than ever necessary to take measures for securing the succession to his only son William. The baronage of Normandy and England were made to do homage to the young prince (1119), who shortly afterwards married Matilda, daughter of Fulk of Anjou, an alliance by which Henry hoped to turn a dangerous foe into a firm friend, and to secure at least the chance of a rich inheritance. All these hopes were, however, shattered by the death of William (1120). Deprived of an heir to his throne, Henry now married Adeliza, daughter of Godfrey, count of Louvain (1121), but the marriage unfortunately proved childless. Shortly afterwards another rebellion, headed by Count Waleran of Meulan, broke out in Normandy (1123). The rebels were emboldened by the assistance of the king of France and the count of Anjou, but were entirely defeated at Bourgtheroulde (1124). The terrible vengeance taken by Henry on this occasion, together with the death of William, son of Robert, in 1128, seems to have finally crushed the opposition in Normandy. The death of Duke Robert in 1134 removed the last object round which the schemes of rebellion or the intrigues of France could centre. Meanwhile Henry had recalled his daughter Matilda, now a widow, from Germany. In default of an heir to the throne, he made the witan swear to accept her as Lady of England and Normandy (Christmas 1126). Next year he gave her in marriage to Geoffrey, son of Fulk, count of Anjou, hoping thereby to secure the objects frustrated by the death of his son. Fate, however, thwarted the immediate success of these schemes.

The annals of England, after the expulsion of Robert of Belesme, are uneventful. In his ecclesiastical policy Henry, without giving up the control over the church which

his father had asserted, was forced to recognize to a certain extent the advancing claims of Rome. His dispute with Anselm was conducted with good temper on both sides, and was brought to a satisfactory conclusion. Anselm had made no objection to the ecclesiastical supremacy claimed by Rufus, but the decrees of the Lateran Council (1099) obliged him to resist a similar claim when put forward by Henry I. He refused to do homage to his new king, or to consecrate the bishops whom Henry invested, according to ancient custom, with the symbols of ecclesiastical dignity. Neither side would give way. Henry continued to make bishops as before, and Anselm refused to consecrate them. In 1103 he left England. For the next three years the affairs of Normandy hindered the settlement of the question, but a compromise was effected in 1107. The pope, Paschal II., consented that homage should be done to the king, while Henry gave up his claim to investiture with the ring and staff. The question thus settled was not reopened till the days of Becket. In other respects Henry acquiesced in the tendency of the time towards ecclesiastical separatism, and countenanced the decrees of the synod of 1102, which forbade the marriage of the clergy and the tenure of temporal offices by ecclesiastics. He showed his care for the church by the establishment of two new sees, those of Ely (1109) and Carlisle (1133), taken respectively from the unwieldy dioceses of Lincoln and York. In the old quarrel between York and Canterbury, Henry supported the claims of the southern metropolitan against Archbishop Thurstan. On Anselm's death, Henry was guilty of leaving the see vacant for five years, but in his other dealings with the church he seems to have been actuated by worthy motives. He refused, however, to open her high places to Englishmen, and till near the end of his reign no native attained the dignity of prelate. The same exclusive spirit made itself felt in the appointments to temporal office. But although political liberty and influence were not granted to Englishmen under Henry I., the English nation as a whole acquiesced gladly in his rule. Its chief wants were justice and order, and protection from feudal tyranny; and these blessings it obtained. The necessities of his position compelled Henry to rely mainly on his English subjects. As a counterpoise to the local influence of the baronage, he did his best to restore to activity the old popular institutions of the hundred and the county-court, of tithings and frankpledge, of watch and ward. His frequent progresses through the country, for judicial and other purposes, form a link between the annual courts held by the Conqueror and the regular circuits of the justices established by Henry II. In the administration of justice and the toils of government he relied on new men, raised from the ranks and dependent on himself for their position. The older baronage he habitually depressed, and every unsuccessful rebellion thinned the ranks of the feudal nobility, while it tightened the link between the king and the nation.

Thus secure at home, Henry was dreaded by his neighbours within the four seas. Over Scotland, Ireland, and Wales a sort of ecclesiastical supremacy was recognized. On the northern frontier there was peace throughout the reign; on the western there was more disturbance. Henry settled a colony of Flemings in Pembroke (1111), and made two expeditions into Wales (1114, 1121), in one of which he received the submission of several Welsh princes. The profound peace which England enjoyed for a period of thirty-four years is the best testimony to Henry's merits as a king. As a man his character is not admirable, nor yet wholly to be condemned. He was hard, merciless, and unforgiving, but not wantonly cruel. He sometimes displayed a grim humour which reminds one of his father; but he never gave way to the vices and brutality of Rufus, nor to the jovial good-humour which was so winning in his

eldest brother. Regarded as the "Lion of Justice" by his people, and bitterly regretted after he was gone, he was not a popular king. He died, after bequeathing his crown to his daughter Matilda, near Rouen (December 1, 1135). His body was carried to England, and buried in the abbey he had founded at Reading.

HENRY II. (1133–1189), king of England, son of Geoffrey, count of Anjou, and Matilda, daughter of Henry I., was born at Le Mans, March 5, 1133. He was left in France during the first part of his mother's struggle with Stephen, but was sent over to England in 1141. There he remained four years, in the charge of his uncle, Robert of Gloucester. In 1147 he took a more active part in the war, but was not successful. He now sought the aid of David, king of Scotland, and was knighted by him (1149), but nothing came of the alliance with that prince. On his return to Normandy (1151), Louis VII. conferred the duchy upon him, and later in the year he became, by his father's death, count of Anjou. In 1152 he married Eleanor of Aquitaine, and added Poitou and Guienne to his dominions. He again went to England in 1153, and the great position he had won on the Continent turned the scale in his favour. After a short struggle Stephen consented to negotiate. By the treaty of Winchester (November 7, 1153) it was settled, among other things, that Stephen should reign undisturbed during the rest of his life, and that Henry should succeed him. A year later Stephen died, and Henry took quiet possession of the throne. He was crowned on December 19, 1154, and at once issued a charter of liberties, in which he confirmed the charter of Henry I.

His reign falls into three main periods. During the first Henry was occupied in restoring and maintaining order. The second is that of the quarrel with Becket. The third is for the most part a period of rebellion and trouble, the consequences of that quarrel. Henry's first business was to fulfil the promises made in the treaty of Winchester, and to undo the work of his predecessor. Several of Stephen's castles were abolished, new sheriffs were appointed, the adulterine castles destroyed, the royal domains recovered. In this task the king met with little serious opposition, and his presence generally sufficed to ensure success. In 1156 Henry was able to go to France, where his brother Geoffrey was causing trouble by his claims on Anjou. He had to subdue him by force of arms, after which he allowed him to be chosen count of Nantes. He then exacted homage from his Continental vassals, and himself did homage to Louis VII. At Easter 1157 he returned to England, to complete the restoration of order there. Those of the great barons who had not yet given up their castles had now to do so, and the king of Scotland surrendered the three northern counties. An unsuccessful expedition to Wales followed. In 1158, on his brother Geoffrey's death, Henry secured his inheritance. At the same time he betrothed his second son Henry (the eldest, William, being dead) to Margaret, daughter of Louis. Next year he made an attack

upon Toulonse, which he claimed in right of his wife, but after some successes retired, owing to the opposition of the French king. In a peace made soon after, he retained Cahors, but gave up his claim to the rest of the county. Hostilities between him and Louis were, however, more or less continuous during this time, in spite of the efforts of Alexander III. In January 1163 Henry returned to England after five years' absence, and his quarrel with Becket immediately began.

Becket had been consecrated archbishop of Canterbury in June 1162. He at once resigned his temporal offices and demanded the restitution of lands alienated from his see. At a council at Woodstock he refused to pay the tax of two shillings per hide demanded by the king. A little later the struggle was removed to still more dangerous ground. Becket refused his consent to the king's proposal for settling the dispute between the temporal and spiritual courts. Upon this Henry asked him and the bishops whether they would abide by the ancient customs of the realm. So vague a question met with an evasive answer. The bishops would only consent "saving their order." However, at the council of Clarendon (January 1164) the disputed customs were drawn up in the form of sixteen constitutions, and after considerable hesitation accepted by Becket. He nevertheless got absolution from the pope, who refused to confirm the constitutions. Henry now attacked Becket with a series of charges connected with his chancellorship, the result of which the latter evaded by leaving England. Henry took possession of the see, and expelled Becket's friends and relations. The greater part of the next five years he spent abroad. During this time he was occupied in maintaining order among his unruly vassals, checking the intrigues of Louis, and negotiating with the pope. He also obtained possession of Brittany for his son Geoffrey, and betrothed Richard to Alice, daughter of Louis. With the object of securing the succession he had his son Henry crowned by the archbishop of York at Westminster (June 1170). The young king's wife was not crowned with him. Louis, taking this as an insult, invaded Normandy, and only made peace with Henry on condition that he would restore Becket to favour. A meeting between the king and the archbishop ended in a compromise, and the latter returned to England. His first step was to suspend the archbishop of York and other bishops who had taken part in the coronation of the young king, and Henry, on hearing of this, uttered the angry words that led to Becket's murder. The pope was, however, in too critical a position to quarrel seriously with Henry. Negotiations between them ended in a meeting with the legates at Avranches (1172), in which Henry received absolution, and promised to abolish all the bad customs introduced during his reign. He had employed the interval in making an expedition to Ireland, and appropriating the conquests made by Strongbow a few years before.

The ecclesiastical quarrel seemed to have died away, but its consequences were felt in the great rebellion of 1173. A confederacy was organized by the French king, the count of Flanders, the king of Scotland, and Henry's sons, with the object of placing the young Henry on his father's throne. The first campaign was indecisive, but on the whole favourable to the king. In view of a general attack which was to be made next year, Henry crossed over to England and did penance at Becket's tomb. Fortunately his justiciar, De Lucy, captured the Scotch king at Alnwick, and the rebellion in England was speedily put down. William the Lion was forced to buy his release by doing homage to Henry; the other confederates made peace; and Henry was left stronger than ever. He at once proceeded to secure his position by further legislative enactments, and henceforward he had no trouble in England. But he was

involved in constant difficulties with his sons and with the French king, owing to the mutual jealousies of the former and the intrigues of the latter, to which Henry's partiality for his youngest son John and his refusal to allow the marriage of Richard with Alice gave rise. A war between the brothers in 1183 was brought to an end by the death of the young Henry in the same year. The feud broke out again in 1184, and continued at intervals, in spite of the death of Geoffrey in 1186, to the end of the reign. At length Henry's apparent intention to name John as his successor forced Richard to ally himself with Philip II, and in the war that followed Henry was beaten at all points. He was forced to make a disgraceful peace, the terms of which, together with the discovery that John was among his enemies, broke his heart. He died at Chinon, July 6, 1189, and was buried at Fontevraud.

Henry's legislative activity, which was great and constant, deserves special notice. His aim was the consolidation of royal power by means of a centralized system of justice and administration. The Constitutions of Clarendon were an essential part of this scheme, designed to bring the clergy, as well as other classes of the nation, under the rule of law, and to prevent an ecclesiastical "imperium in imperio." Other enactments, as the Assize of Clarendon (1166), were intended to perfect the judicial system and to supersede the baronial by the royal courts. The system of recognition by jury took the place of trial by battle. The grand jury was organized for the presentment of criminals for trial. The jury system was further employed for the inquiry into the conduct of the sheriffs (1170), and for the assessment of the Saladin tithe (1188). The circuits of the justices itinerant were, after repeated experiments, brought to something like perfection, and a high court of justice formed out of the Curia Regis, which was the origin of the Court of King's Bench. By the commutation of feudal service for scutage, and by the Assize of Arms (1181), which revived the national militia, Henry made himself independent of the baronage, and formed that alliance between king and people which was the surest basis of his power. Whatever may be said against his private character, the wisdom and steadiness with which he pursued these aims, and the permanence of the mark that he left upon the constitution, secure him the title of a great king.

HENRY III. (1207–1272), king of England, eldest son of John and Isabella, was born on October 1, 1207, and was just nine years old on his father's death. Ten days after that event he was crowned at Gloucester (October 28, 1216). His long reign falls into four periods,—that of the regency, ending with the fall of De Burg; that of government by favourites, which led to the Mad Parliament; the period of the Barons' War; and the short period between the close of the war and Henry's death. At his accession the whole country was in rebellion, and Louis with his Frenchmen held the east and south. In this crisis it was fortunate that the government fell into the hands of such a man as William Marshall, and that the pope gave him all the assistance in his power. The acceptance of the charter at once recalled many to their allegiance, and the defeat and retirement of Louis broke up the opposition. The charter was confirmed (1217) and order rapidly restored. The Jegate

Qualo aided the earl marshal and Archbishop Langton in the work. On Marshall's death (1219) Pandulf took Qualo's place, and asserted the papal authority in a way which obliged Langton to make a personal protest at Rome. Pandulf was recalled, and Hubert de Burg, the justiciar, ruled with Langton till the latter's death (1228), and alone afterwards. The influence of Peter des Roches, bishop of Winchester, the head of the foreign party and guardian of the king's person, was successfully resisted. Meanwhile a last outbreak of pure feudalism under Falkes de Breaté was put down, and the charter again issued in its final shape (1227). But the worst plague of the reign, the influence of foreign favourites, had already made itself felt, while another great evil, the financial exactions of Rome, was causing much discontent. An expedition to Poitou, opposed by De Burg, caused the first quarrel between him and the king. Shortly afterwards Peter des Roches returned from a temporary banishment, and gained such influence over Henry that he dismissed De Burg with insult and ingratitude (1232). From this point his real reign may be said to have begun.

The bad promise of his youth was amply redeemed in the events of the next twenty-six years. Under the influence of Peter des Roches, foreigners began to flock to the court, and even foreign mercenaries were introduced into England. Richard, earl marshal, who openly rebuked the king for this conduct, was outlawed, but other barons took up his cause, and collisions between them and the king's troops took place. Civil war appeared imminent, when Archbishop Edmund persuaded Henry to dismiss Peter des Roches, and the danger was avoided for the time (1234). But the king's partiality for foreigners was a constant source of discontent. In 1236 he married Eleanor of Provence. Two uncles of the queen, William, bishop of Valence, and Peter of Savoy, came over with her, and were immediately placed in positions of honour and emolument. In 1238 Henry married his sister Eleanor to Simon de Montfort, an event which nearly produced an outbreak. Resistance already centred in the Great Council, which in 1236 had declined "to change the laws of England," and supported the bishop of Chichester in his refusal to give up the great seal at the king's demand. Henry's personal extravagance caused him much embarrassment, and the extortions of the papal see pressed heavily on the church. In 1242 the barons refused to give the aid demanded by the king for another expedition to Poitou, and when they met again after his return, they joined with the clergy in a general protest against his misgovernment (1244). In order to remedy this state of things, it was proposed that the king's advisers should be chosen by the parliament, as it now began to be called, but Henry found means of evading the demand. Hitherto his brother Richard, earl of Cornwall, had been the leader of the opposition, but Simon de Montfort, earl of Leicester, was now becoming the centre of constitutional resistance. In 1246 the king's step-father, the count of La Marche, died, and Henry's half-brothers came to England, bringing with them a fresh crowd of hungry followers. The demands made upon the great cities, especially London, upon the Jews, and upon the clergy, to meet the expenses caused by the king's favourites, were constantly on the increase. Owing to the cessation of the office of justiciar since the fall of De Burg, the judicial system was falling into decay, and crime of all kinds was rampant. At the same time the pope, engaged in his great struggle with Frederick II., regarded England as an "inexhaustible spring of wealth," and redoubled his demands. He won over most of the bishops by supporting them in their claim to inspect the monastic houses in their dioceses, and the church, deprived of its natural head,—for Boniface, an uncle of the queen, was archbishop of Canterbury,—was disunited and helpless.

Grosseteste, bishop of Lincoln, was almost alone in his efforts to follow in the steps of Stephen Langton. He and De Montfort were at one in their desire for reform, but the nation was not yet ready. Two mistakes on the part of Henry brought matters to a crisis. He had conferred the government of Gascony on De Montfort in 1248, and the latter had reduced the province to obedience. But accusations made against him found ready audience with the king, who feared and disliked his brother-in-law. The result was a bitter quarrel (1252), which Henry followed up by superseding De Montfort in his government, and sending his eldest son Edward to take his place. This had the effect of throwing the earl once for all into the arms of the national party. A little later an event occurred which forced that party to take active measures. The pope persuaded Henry to accept the kingdom of Sicily for his second son Edmund, and to bind himself to pay the expenses of its conquest, together with a large debt already incurred (1255). This important scheme was entered into without the knowledge of the parliament, and the nation suddenly found itself pledged to an undertaking which had purely dynastic or papal objects. The coalition of pope and king produced a corresponding union of the church and the baronage, and the troubles of the year 1257, Scotch and Welsh inroads, together with a failure of the harvest, united the nation against the Government.

A parliament which met at Westminster (April 1258) forced Henry to promise reform, and elected a committee of twenty-four to act for the king till a complete scheme could be drawn up. On June 11th the assembly, called afterwards the Mad Parliament, met at Oxford. A council of fifteen, of whom two-thirds were on the baronial side, was appointed, who, together with twelve representatives of the "community," were to take charge of the government and meet in parliament thrice a year. Hugh Bigod was named justiciar, other offices were filled up, the castles were entrusted to Englishmen, and four knights were summoned from each county to declare grievances. These reforms, together with certain general enactments, went by the name of the Provisions of Oxford. The king's authority was completely superseded, and the rule of a baronial oligarchy established. Next year, owing to the demands of the knighthood, who felt themselves neglected, a further series of Provisions was issued. The Sicilian project was formally repudiated, and a final peace made with France, in which the claim on Normandy and other districts was renounced. But beyond this the baronial Government did nothing. The nation testified its disappointment, and a quarrel took place between the earls of Leicester and Gloucester which divided the baronial party. The king took advantage of this state of affairs, and in 1261 obtained absolution from the Provisions at the hands of the pope. He then fortified the Tower, deposed the baronial justiciar, and soon began to rule as before. In this crisis the baronial party made a bid for popular favour by summoning representatives of the counties to a parliament, but the reaction was for the time complete, and Henry had leisure to go to France in order to win over Louis IX. to his side. In 1263 hostilities broke out on the Welsh border, and the barons seized the opportunity to renew their attack on the king. After some months of desultory warfare, it was agreed to submit to the arbitration of Louis. That king, in the Mise of Amiens, decided in favour of Henry, and annulled the Provisions. Leicester at once appealed to arms. The battle of Lewes (May 14, 1264) was a complete victory for him, and put the king and his eldest son into his hands. For a time he was master of the country, but the party he headed was not that which had been dominant six years before, and Henry now had many adherents among the

greater barons. Nevertheless, for more than a year he remained practically a prisoner in the hands of De Montfort. At a parliament which met in June 1264, and at which knights of the shire were certainly present, a constitution was drawn up, which, while preserving to the king a high position as head of the executive, placed supreme power in the hands of the "community." Early next year, in a parliament to which members from the boroughs as well as from the counties were summoned, this constitution was confirmed, and Henry swore to observe it. In accordance with the settlement made at Lewes, Edward was now to be released. His father was already supposed to be at liberty, but in reality both he and Edward were kept in restraint. Edward's escape (May 1265) caused an immediate renewal of the war, and at the battle of Evesham (August 4, 1265) De Montfort was killed and Henry set free. Two years later the war was practically concluded by the capture of Kenilworth. Henry had little to do with the conduct of the war, and acquiesced in the arrangements made by his son for the pacification of the country. His triumph was, however, complete, and for the rest of his reign the kingdom was at peace. He died on November 16, 1272, leaving behind him the memory of one whose virtues were of the priestly kind, and whose worst vices were those of indulgence, ill-temper, and prodigality. As a subject he would have been harmless, and even perhaps respectable; as a king he was weak, hasty, imprudent, equally incapable in the position of a ruler, an administrator, or a general.

HENRY IV. (1366–1413), king of England, only son of John of Gaunt and Blanche, daughter of Henry, duke of Lancaster, was born in 1366. At the age of fifteen he married Mary Bohun, and in 1385 was made earl of Derby. Two years later he was one of the five lords appellant who impeached the earl of Suffolk and others, and took part in the proceedings of the Merciless Parliament. He acquiesced, however, in Richard's return to power, supported the king in his *coup d'état* of 1397, and became duke of Hereford. His quarrel with the duke of Norfolk led to his banishment shortly afterwards, and on his father's death Richard denied him the succession to his title and inheritance (1398). Next year he took advantage of Richard's absence in Ireland to reassert his rights. He landed in Yorkshire, took Bristol, and seized Richard (August 19) near Conway Castle. At a parliament which met on September 30th he claimed the throne on the ground of his descent from Henry III., the right of conquest, and the necessity of reform. He was accepted by the parliament; Richard was forced to abdicate; and Henry was crowned (October 13, 1399). The last of his three claims gives the explanation of his policy. He had won the favour of the church by pledges in favour of orthodoxy; the circumstances of his accession and the difficulties of his government forced him to make concessions to the House of Commons, which raised that body to a position it did not again attain for more than two centuries. The first part of his reign was occupied with the suppression of the revolts, not only of the defeated party, but also of his own discontented adherents. These troubles were complicated by hostile relations with

France, Scotland, and Wales. Charles VI. was inclined to take up the cause of his daughter Isabella, wife of Richard II., and on the death of the latter (February 1400) demanded her and her dowry back. The duke of Albany in Scotland was hostile to Henry, and Owen Glendower raised a national revolt in Wales. The first attempt at insurrection was made by the earls of Richard's party early in 1400, but their plans were discovered, and their forces crushed piecemeal. Most of the leaders fell victims to popular vengeance. A more serious rebellion was that of the Percies (1403), hitherto Henry's staunchest supporters. Hotspur and his father thought themselves ill requited for their services, and made common cause with Glendower and other malcontents. A junction of the northern army with the Welsh was prevented by the battle of Shrewsbury (July 21, 1403), in which Hotspur was killed. Northumberland submitted and was pardoned. But the danger was not over. The north was still in a state of ferment, the war in Wales went on, and a French fleet ravaged the southern coast with impunity. Henry's vigilance and activity were, however, equal to the task. A plot to carry off the young earl of March (January 1405) was foiled, and a fresh outbreak in the north was crushed. Scrope, archbishop of York, and Mowbray, earl marshal, who led the rebels, were taken and executed. The king had already got into his power the son of the duke of Albany; he now captured James, the heir-apparent to the Scotch crown, as he was on his way to France; and the murder of the duke of Orleans removed his chief enemy in that country. Thus secured from danger abroad, he put down a final rebellion in the north, drove Glendower back into his mountains, and henceforward had no trouble at home (1408). The late crisis had, however, compelled him to make important concessions to the House of Commons. He promised (1407) to act solely by the advice of a council nominated with their approval, and submitted to the appropriation of his revenue and to other limitations. Throughout his reign he was hampered by want of money, and the regular exercise by parliament of the right to withhold supplies gave that body great control over his actions. He had seized the crown as the champion of orthodoxy. He had therefore to pay for ecclesiastical support by persecuting Lollards against his will, while he did not dare to act upon the suggestion of the Commons that church property should be converted to purposes of state. Thus limited, his foreign policy was not energetic. He had enough to do at first to defend his coasts, and though he afterwards seized the opportunity afforded by civil war to invade France (1411), his efforts were in general confined to strengthening his dynasty by foreign marriages. In his later years he was a confirmed invalid, and had to entrust much power to his eldest son, with whom he was not always on the best of terms. He died on March 20, 1413, and was buried at Canterbury. A cautious, crafty, resolute man, naturally inclined to fair dealing and clemency, but on occasion unscrupulous and cruel, he was successful in the great enterprise of his life, and has the credit of seeing that the power he had usurped could only maintain itself by resting on a constitutional basis.

HENRY V. (1387-1422), king of England, eldest son of Henry IV. and Mary Bohun, was born August 19, 1387. Early bred to arms, his first military effort was not successful, for at the age of thirteen he commanded an expedition to Wales which was defeated by Glendower. Three years later he was present at the battle of Shrewsbury, and in 1408 he revenged himself on Glendower by driving him back to Snowdon. At the same time his position in the council, at the head of which he appears after 1410, gave him experience in affairs, and proves the confidence already felt in his political ability. The stories of his youthful extravagance

and dissoluteness are unfounded, and, as the above facts show, improbable. Although his father appears to have been jealous of his popularity, he was practically at the head of affairs for some years before the death of Henry IV. Three weeks after that event he was crowned (April 9, 1413), and entered upon his inheritance with the good-will of all classes of the nation. So unanimous was the support he met with in parliament that constitutional affairs cease to have any interest during his reign. In his ecclesiastical policy he followed the lines laid down in 1401, with much greater heartiness than his father had shown. His persecution of heretics caused a conspiracy to surprise him and his brothers, which was discovered and put down with some severity (January 1414). Sir John Oldcastle, the head of the Lollards, was condemned to be burnt, and though he escaped for the time, he was again taken in 1417, and put to death. Henry's orthodoxy brought him into connexion with the emperor Sigismund, then engaged in settling the affairs of the church at the council of Constance, and his assistance was very instrumental in the healing of the great schism. But the great work of his life was the conquest of France. It was with this object that he issued a kind of general amnesty on his accession, and appealed to the nation as a whole to support him. War was resolved on by parliament, and Henry laid claim to the French crown. This demand was afterwards reduced to one for all the districts which the English kings had ever held in France. Such claims as these, of course, precluded all negotiation. The expedition was not delayed by a conspiracy to carry off the earl of March, which was discovered before it was ripe, and on August 14, 1415, the English army landed at Havre. Harfleur was soon taken, but the English losses were so great that Henry resolved to retreat to Calais. On October 25th the French army that opposed his march was cut to pieces at Agincourt. The next two years were spent in preparations for continuing the war. In 1417 Henry again invaded France, took Rouen (1419), and with the assistance of the Burgundian party forced Charles VI. to grant his demands. By the treaty of Troyes (1420) it was arranged that he should marry Catherine, take the government in hand at once, and succeed on Charles's death. This disgraceful treaty had, however, the effect of reviving the national party in France, and during Henry's absence in 1421 the English began to lose ground. He hurried back to France, but before he had had time to recover his position, he died at the castle of Vincennes, August 31, 1422. A great soldier, an able politician, a skilful diplomatist, a generous, pure, and high-minded man, he was one of the noblest and most popular of English kings. But these good qualities should not blind one to the fact that he was a religious persecutor; and that he plunged his country into an unjust and hopeless war.

HENRY VI. (1421-1471), king of England, only son of Henry V. and Catherine of France, was born on December 6, 1421, and was therefore only eight months old at his father's death. He can hardly be said ever to have reigned, for his long minority passed into another kind of tutelage, during which the influence of his wife and favourites prepared the way for civil war. Ten years of anarchy culminated in his dethronement, and ten years more of wandering and imprisonment fill the interval between that event and his death. The chief interest of the first thirty years of his life lies in watching the decay of English power in France; that of the last twenty is to be found in the civil wars which resulted from the misgovernment of the preceding period. Although the English had lost some ground towards the end of Henry V.'s reign, their position, when the duke of Bedford undertook the task of continuing his brother's work, was very favourable. They held the north

and centre of France, while Burgundy held the eastern districts. The alliance with Duke Philip was strengthened by a marriage between his sister Anne and the duke of Bedford. The Scotch king, James I., was released from captivity, in order that England might be relieved from danger on that side. Thus strengthened, Bedford was able to apply himself vigorously to the conquest of France, towards which the battle of Verneuil (1424) was an important step. But the English cause had already received its first great blow in the marriage of the duke of Gloucester with Jacqueline of Hainault, which destroyed the good understanding between Burgundy and England. Bedford for the time managed to stave off the quarrel, and after renewing his union with Burgundy, laid siege to Orleans, the key of southern France. The capture of the town seemed certain, when the appearance of Joan of Arc turned the scale. The relief of Orleans (1429) was followed by other French successes, and by the coronation of Charles VII. at Rheims. The capture of Joan did little for England, for the spirit she had inspired survived her loss, and her death (May 1431) only nerved the French to fresh efforts. It was in vain that Bedford had Henry crowned at Paris (December 17, 1431). The young king remained in France nearly two years (April 1430 to February 1432), but his presence did not turn the tide of French success. On the side of England the supply of men and money was falling short, while on that of France a new type of commanders was coming to the front, who were not inclined to repeat the disastrous blunders of Crécy and Agincourt. The death of Bedford's wife (November 1432) broke the link that bound Burgundy to England, and negotiations for peace were set on foot. These culminated in a great congress at Arras (July 1435), but the demands of the two countries were found incompatible, and the war was renewed. Bedford's death (September 14, 1435) finally destroyed all hope of recovery in France. Burgundy at once made peace with Charles VII., and the English commanders who succeeded Bedford were constantly defeated. Paris was retaken, Normandy overrun. Repeated efforts on the part of England led only to further exhaustion. Meanwhile negotiations for peace had been continued at intervals, and led in 1444 to a truce, during which Henry was married (April 22, 1445) to Margaret, daughter of René of Anjou. It was hoped that this marriage, together with the cession of Anjou and Maine, would lead to a permanent peace, and save Normandy and Guienne. But though Anjou and Maine were actually surrendered in 1448, the truce was broken next year, and before the end of 1450 the whole of Normandy was lost. In 1451 Guienne was reconquered by the French, and in 1453 Calais alone remained to England. The war was practically at an end.

Its conclusion coincides with the period when the two parties that divided England were just about to appeal to arms. The civil war was in great measure the result of the defeats abroad, as those defeats themselves were in part the consequence of discord at home. Quarrels between the chief members of the reigning house were the origin of its weakness; financial embarrassment, a divided foreign policy, and a feeble administration brought disgrace on the king and his advisers; family feuds and a long tale of mutual injuries added bitterness to political differences. Eventually an outburst of popular discontent kindled the train so long prepared, and the champion of order and good government began a struggle in which the original objects were soon lost sight of, and which ended only with the death of the king whose innocent imbecility had caused the disorder. To check the rivalry of Henry's uncle, the duke of Gloucester, and his great-uncle, Cardinal Beaufort, was beyond the power of the council. Bedford alone could appease the quarrel, and Bedford's presence in England

meant disaster in France. The quarrel between them and their adherents was complicated by the existence of the Lollards, and the question of peace or war. In both matters Gloucester, as persecutor of the Lollards and head of the war-party, appears to have taken the more popular side. The coronation of the young king at Westminster (November 6, 1429) put a formal end to the regency of Bedford and Gloucester, but not to the intrigues of the latter. The House of Commons was unable to interfere with any effect; the Lords were mostly engaged on one side or the other. The death of Bedford removed the only guarantee of peace, and Gloucester attacked Beaufort with more virulence than ever after his brother's death. In the midst of these troubles Henry VI. came of age (1442). Had he been a great statesman, he would have found an almost hopeless task before him. But, unfit as he felt himself to be, he naturally shrunk from politics, and was much more intent on completing his foundations at Eton and Cambridge than on healing the disorders of his country. The work of government was left mainly in the hands of Cardinal Beaufort and the earl of Suffolk, who did their best to secure peace with France. On the other side the dukes of Gloucester and York headed the opposition, and took up the cry of reform, with the object of infusing vigour into the government at home and abroad. Suffolk, however, won a great victory in the truce with France (1444); and through the young queen Margaret, whose marriage was chiefly due to his exertions, he obtained complete influence over the king. The suspicious death of Gloucester (1447), followed in six weeks by the death of his rival Beaufort, together with the appointment of York to the governorship of Ireland, left Suffolk master of the situation. But such a position could not be long maintained in the face of the odium which always attaches to a favourite, and the complete failure of his foreign policy brought about his fall (1450). The king in vain attempted to save him, and by so doing shared his unpopularity, while the partial concessions he made to the demands of the rebels under Jack Cade only postponed the inevitable outbreak. The duke of York now made himself the mouth-piece of popular discontent. When the final loss of France had exhausted the country's patience, and the birth of an heir to the throne had destroyed his hope of the succession; he took advantage of Henry's mental derangement to claim the protectorate (1453). It was granted him early next year, but in 1455 the king recovered his senses, and York was deprived of power. Unable to endure this he marched on London, and on May 22, 1455, the Wars of the Roses began in the battle of St Albans. The effect of the battle was to bring the queen to the front as the leader of the royalists, and to make the quarrel between her and York irreconcilable. During the four years of uneasy quiet which followed the first collision, Henry tried hard to keep the peace. But all his efforts were vain. When the struggle broke out anew, and the Yorkists won the battle of Northampton, he was forced to consent to an arrangement by which his son was excluded from the succession and York recognized as heir to the kingdom (1460). The settlement was of short duration. York himself lost his life at Wakefield, but his son seized the crown and was acknowledged king (March 4, 1461). The battle of Towton brought the struggle to an end for ten years, and the capture of Henry in 1465 seemed to secure Edward IV. on the throne. Five years later a sudden revolution hurled him from it, and restored the wretched prisoner for a while to liberty, but the battle of Barnet destroyed his hopes again. He had time to know that his son had died at Tewkesbury, that his wife was a prisoner, and that his cause was finally lost, before death released him from captivity on May 21, 1471. Gentle, pure, and generous, full of good intentions, enthus

siastic in the cause of religion and learning, he was utterly without the qualities which were indispensable to a mediæval king, and he paid the penalty of incapacity in a miserable death and in the destruction of his house. But this very incapacity was an element of the utmost importance in the history of his time. The weakness of his character made him the puppet of contending factions, and his well-meant but misguided efforts to govern England as a constitutional king led only to anarchy and the temporary downfall of the constitution.

Original Authorities for the above three reigns.—Thomas of Walsingham, *Hist. Anglicana*, and *Ypodigma Neustria*; *Annales Henrici Quarti*; *Continuatio Eulogii Historiarum*; *Chronique de Waurin*; *Annals of St Alban's Abbey*, by John of Amundesham and John Whethamstede; *Royal and Historical Letters (Henry IV.)*; Capgrave's *Chronicle of England*, and *Liber de Illustribus Henricis*; *Memorials of Henry V.* (Redman, &c.); *Letters, &c., illustrative of the reign of Henry VI.*; *Political Poems*. Modern Authorities.—Besides those already given above, *Nicolas's History of the Battle of Agincourt*; *Gairdner's Preface to the Paston Letters*. (G. W. P.)

HENRY VII. (1456–1509), king of England, was the founder of the Tudor dynasty. On his mother's side Henry belonged to the illegitimate branch of the house of Lancaster, being descended from John of Gaunt and Catherine Swinford, and it was only in the absence of nearer heirs that he was accepted as the representative of that house. On the father's side he was sprung from the marriage of Owen Tudor, a Welsh gentleman, with Catherine, widow of Henry V., and this family name became the name of the line of kings which he founded. On the complete overthrow of the Lancastrians, especially after Richard had won the throne by putting his nephews out of the way, Henry, under the name of the earl of Richmond, appeared as the centre of the opposition. From his exile in Brittany or France he schemed for the overthrow of Richard, and made an expedition to England to support the unsuccessful rising of Buckingham. The increasing unpopularity of Richard gave him greater success in his second enterprise. He landed at Milford Haven in order to profit by the good-will of his kinsmen the Welsh, and marching into Leicestershire defeated Richard at the battle of Bosworth, thus ending the Wars of the Roses (1485). Soon after he married Elizabeth daughter of Edward IV., and so the White Rose and the Red were united. Henry, however, was not allowed to enjoy the crown in peace. Two pretenders, one after another, led a rising against him. Lambert Simnel, personating the earl of Warwick, son of the duke of Clarence, gathered the Yorkists about him in Ireland, and landing in Lancashire advanced as far as Stoke in Staffordshire, where he was defeated and made captive (1487). Next arose Perkin Warbeck, a Fleming, who, pretending to be one of the princes murdered by Richard in the Tower, received much countenance abroad and in Scotland, and had many supporters among the discontented at home. But when he ventured to land in Cornwall, he was captured and finally executed (1499). These risings troubled the reign of Henry, but did not shake his throne. He ruled with a firm hand; he took care to repress the nobles, already almost exterminated in the civil war, in this case continuing the policy of Edward IV.; he put down the practice of maintenance, by which they kept bodies of retainers ready to support them in battle, and in every way sought to concentrate in the person of the king the whole power of the nation. Henry was a parsimonious and

calculating ruler, who avoided war, gained by diplomacy what other sovereigns attempted by force, kept a well-filled treasury, and made two brief expeditions into France the occasion of amassing additional wealth. His avarice led him even to revive old and forgotten statutes, and to exact heavy fines from those who had transgressed them, in which evil work he was assisted by the two well-known lawyers Empson and Dudley. His reign is marked also by two marriage arrangements which had great influence on subsequent history. His son Arthur was wedded to Catherine of Aragon. When Arthur died in 1502, a few months after the marriage, Catherine remained in England in order to be united to the younger son Henry, though the nuptials did not take place till after his accession to the throne. The other marriage was that of the young princess Margæret to James IV. of Scotland (1503), which a century after resulted in the union of the crowns. Henry VII. died in 1509, leaving, it is said, a treasure of two million pounds to his successor. He was by no means an amiable or popular sovereign, but did great service in settling and consolidating the kingdom after the long troubles.

The authorities for Henry VII. are—*Memorials of Henry VII.* (with which is published Bernardi's *Historia de Vita Henrici VII.*), and *Letters and Papers illustrative of Henry VII.*, both edited by Gairdner; and Bacon's *History of Henry VII.*, edited by Stebbing.

HENRY VIII. (1491–1547), king of England, was born in 1491, being the second son of Henry VII. and of his wife Elizabeth of York. On the death of his elder brother Arthur in 1502, he became heir apparent to the throne. As younger son Henry had been educated for the church, and it is said that his interest in theology was due to those early studies; but as he was only eleven when his brother died, they could not have been either extensive or profound. His training under the severe and methodical Henry VII. must have been a very careful one; he was deeply interested in the new learning, and was a most accomplished scholar. During his father's lifetime we hear nothing of the young king except as the destined husband of Catherine of Aragon, the widow of his brother Arthur, a lady six years older than himself. It suited the plans of the old monarchs, their parents, that Catherine should be wedded to Henry, and so she remained in England during the seven years of her widowhood. Henry was only eighteen when the death of his father (1509) left the throne of England vacant, as well as set him free to shape his own career. His first important act was to fulfil the contract imposed upon him by his father to marry Catherine. His ministers, almost without exception, were in favour of the marriage. Henry expressed himself highly delighted with his wife. Catherine was fond of him to excess. The disparity of years was not so marked at that early period; Catherine was amiable, accomplished, of the bluest blood in Europe, closely connected with the most powerful dynasties, a queen of whom England with her then diminished prestige might well be proud. For the time all went well, and no one saw in such a simple event the seeds of a great revolution.

Englishmen were not in the mood to anticipate evil at the accession of Henry. In the young king all the conditions requisite for a prosperous reign seemed to be combined in a rare degree. To the dull monotony, varied only by Yorkist rebellions, to the greed, suspicion, and jealousy which made the shady side of the previous reign, succeeded an era of splendour and enjoyment in which every free and generous impulse should have free scope. As Henry united in his own person the lines of the White Rose and the Red, there was no likelihood of a revival of the old broils. Those who grudged to see his Lancastrian father on the throne were well pleased to see it occupied by a son of Elizabeth of York. The hated avarice of Henry VII. had

provided means for the popularity of his successor ; and to Henry VIII. fell the easy and generous rôle of squandering the treasure which his father had amassed. Nor was this the only respect in which the young Henry entered on the fruit of other men's labours. In the Wars of the Roses, and by the policy of Edward IV. and Henry VII., the old feudal nobility had been brought very low. When nothing more was to be feared from that quarter, it was Henry VIII.'s easy task to gather round him the broken remnants, to attach them to his person, and to make them the ready instruments of his will, in short, to convert the representatives of a haughty feudal baronage into submissive courtiers. In character the young Henry was a king according to the people's heart ; even in his faults he was exceptionally fortunate. He was handsome, frank, extravagant, of vast muscular strength, accomplished in all the manly exercises of the time and in the new learning ; he was vain, thirsting for popularity, eager to retrieve the old renown of England, the enemy of France, and dreamt always of renewing the conquests of the Henrys and Edwards. It is not surprising that Henry excited the highest expectations in all classes of his subjects, for his varied character offered an attractive side to all of them. The men of the new learning were charmed by his love of letters. Ecclesiastics saw with pleasure his punctual performance of the duties of religion. All good men were delighted with the excellence and purity of his private life. Statesmen were struck by his capacity for business ; his gaiety and frankness captivated the courtiers ; the prospect of French conquest inspired the warlike and the ambitious. From the description of Henry by the Venetian ambassador, Giustiniani, in 1519, we can easily perceive what impression he must have made on England at his accession :—"His Majesty is twenty-nine years old, and extremely handsome. Nature could not have done more for him. He is much handsomer than any other sovereign of Christendom,—a good deal handsomer than the king of France,—very fair, and his whole frame admirably proportioned. On hearing that Francis I. wore a red beard, he allowed his own to grow ; and as it is reddish, he has now got a beard that looks like gold. He is very accomplished, a good musician, composes well, is a most capital horseman, a fine joustier, speaks good French, Latin, and Spanish, is very religious, hears three masses daily when he hunts, and sometimes five on other days. He hears the office every day in the queen's chamber,—that is to say, vesper and compline. He is very fond of hunting, and never takes his diversion without tiring eight or ten horses, which he causes to be stationed beforehand along the line of country he means to take ; and when one is tired he mounts another, and before he gets home they are all exhausted. He is extremely fond of tennis, at which game it is the prettiest thing in the world to see him play, his fair skin glowing through a shirt of the finest texture." When we take all these facts into consideration, when we remember also that ere long he had raised England from a third-rate position to a level with the greatest powers of Europe, and that for twenty years nothing serious occurred to break the harmony of his reign, we cannot be surprised that Henry was a most popular king.

The reign of Henry falls naturally into two periods, separated by the question of the divorce. During the first period Henry is the splendid and jovial king at home, abroad a figure of the first magnitude in the war and international diplomacies of the time. Both in home and foreign affairs, but particularly the latter, Wolsey was the right hand man of the king, ready, as occasion served, either to transact the whole business of the government, or to be the humble instrument of the king, when the royal hand did actively interfere. In point of fact Henry always was master, and took a keen interest in business. The events

of the first period were concerned chiefly with the foreign wars. At home, with the exception of the execution of Empson and Dudley, the instruments of his father's extortion, who suffered, however, on a trumped-up charge of treason, nothing important occurred. There were Christmas revels, May festivals, tilting matches, in which Henry always shone victorious, and in which he squandered the treasures of his father. But the serious endeavours of the time were directed abroad ; Henry joined his relatives Ferdinand and Maximilian in a league against France. Though Henry took a personal share in the campaign in France of 1513, and won the easy Battle of Spurs, and though Surrey, his general, gained the great victory of Flodden, no substantial result was attained by the war. Henry was duped and then abandoned by his allies. When he was undeceived, he made peace (1514) with France, which was cemented by the marriage of his youthful sister Mary to the old and worn-out Louis XII. Soon after, when Louis was succeeded by Francis I. (1515), and Charles V. entered on the government of his hereditary dominions (1516), the three monarchs who figure so conspicuously as the contemporaries of the Reformation, and whose doings constitute so much of the history of the 16th century, found themselves face to face. With these two and with the successive popes Henry had to do during the rest of his life. Their relations at first were chivalrous and even friendly. Henry never had any chance of success in his canvass for the imperial crown. When it fell to Charles, it made him beyond a doubt the first monarch of the age ; his success placed him in open rivalry to France ; but to Henry, fortunate again, it gave the desirable prospect of being courted by the two rivals, and even of acting as arbiter in their disputes. Henry, however, descended from this lofty position to engage in quarrels which had no concern with the true interests of England. The chimera of French conquest again fascinated him and his people, so that when the false chivalry of the Cloth of Gold had degenerated into war, Henry took the side of Charles. In the campaign of 1523 the English forces advanced to within eleven leagues of Paris, but the war led to no durable and satisfactory result as far as Henry was concerned. The people grew sick of the heavy contributions they were called upon to make, and threatened revolt. After the battle of Pavia (1525), where the French were completely overthrown and their king made prisoner by the armies of Charles, the policy of Henry was completely disturbed. Till that event it had been clear enough. The commercial interests of the country, which were bound up with the Flemish dominions of Charles ; the ambition of Wolsey, who founded his hope of the papal crown on the good-will of the emperor ; the hereditary enmities and warlike instincts of the people, as well as the inclination of the king, coincided conveniently in requiring the imperial alliance. But now France was down, and the balance of power, already a working conception in politics, was destroyed, while Charles in his triumph ignored the claims of Henry, and had more than once disappointed the ambition of Wolsey. Under these circumstances English policy was forced out of its old groove, and an alliance was made with France. In a short time, moreover, interests and passions of a far more momentous nature emerged. The dilettante politics of Henry's early career were to be superseded by occupations of a tragically earnest nature. Adventurous enterprises abroad were to give place to real interests at home, and the jovial young king was to be transformed into the stern, self-willed, and often cruel revolutionary. The serious and important part of Henry's life therefore is still to come : but before leaving the earlier period it is well to remark that it lasted twenty years, or more than half of his reign ; that during these years Henry was popular in the highest degree ; and especially that he

had gratified the national pride of his subjects by restoring England to a leading position in Europe. This should not be forgotten during the troubled and more questionable events that were to follow.

The year 1528 may justly be fixed as the turning-point of Henry's life. By that time the divorce had become a national and even a European question, and Henry had decisively committed himself to the course which was to result in the separation from Rome. It is not clear when the plan of a divorce began to take shape in Henry's mind; it was the slow result of a variety of causes which were not clear to the king himself. We know, however, that Anne Boleyn returned to the court of England in 1522; that she made quite a sensation there as soon as she appeared; and that among other admirers, married and unmarried, Henry soon expressed a decided preference for her. On the other hand, he seems to have been alienated from Catherine long ere the question of divorce became public; if we may trust a statement of his own, he had abstained from her bed since 1524, and his coldness for her increased with his love for Anne. That his scruples regarding his marriage awoke about the same time was certainly a very convenient coincidence. The danger, however, of a disputed succession in the absence of male heirs was a real one. The situation probably justified such an extraordinary measure as a divorce, though we must recollect that the raising of a second family, rival to Mary the daughter of Catherine, might precipitate the very crisis which men feared. Still we must admit on the whole that the national interest and the inclination of Henry coincided, and that concern for his kingdom probably had a large part in the mixed motives which urged him to seek a divorce.

When the demand for a divorce was first formally laid before the pope in 1527, no one anticipated that it would encounter so many difficulties. The great opponent of it was Charles V., who loyally supported his aunt, and who, as the event proved, had the pope entirely in his power. But for the emperor, Clement would soon have arranged everything to the satisfaction of the English court. As it was, he sought safety in delay. Thus he declined giving any decisive answer himself, and when he delegated the case to Wolsey and Campeggio, he managed still further to defer the question and then to revoke it to Rome (1529). By that time Henry's patience was exhausted. As early as 1528, and as if sure of a speedy decision in their favour, the king and Anne were living familiarly together under the same roof. Their disappointment was natural, and Henry soon began to take more active measures. He appealed from the pope to the universities. Notwithstanding his life-long services Wolsey was discarded, because he was supposed not to have been sufficiently earnest about the divorce. The same year (1529) a parliament was called, which proved to be the ready auxiliary of the king in his new policy. This parliament, which sat at intervals from 1529 to 1536, had little independent or substantive power; it was made up largely of the nominees and creatures of the court, and seldom moved but at the royal initiative. Still it was well that the old forms should be recognized in the great changes that were coming, and significant that the strong-willed Tudor felt it safe to have the nation at his back. The changes themselves were gradual, and were by no means disagreeable to the advanced and influential part of the nation. Only a very small minority had any sympathy with the Lutheran movement; but many wished to see the church reformed, to have her power curtailed, and that England should take up a more independent attitude towards the pope. Under these circumstances Henry found it easy to carry the majority, especially the active and progressive part, of the nation with him. In no case was the parliament of 1529 conscious of its destiny; what it con-

templated was not a revolution but only some necessary reform; it, as well as Henry, would have been astonished to hear that they were working on the side of Luther. Yet the parliament soon proceeded to take some very decisive steps. In 1529 the probate duties and mortuaries (or burial fees) exacted by the church were curtailed; the clergy were prohibited from following secular employments; residence was enforced, and pluralities forbidden. In 1531 the clergy were laid under the charge of *præmunire*, which they bought off by the payment of £118,000, and the acknowledgment that the king was supreme head of the church. In 1532 the abuses of "Benefit of Clergy" were reformed, annates abolished conditionally, and the independent legislative power given up by convocation. Soon after the king took a step which precipitated the crisis; he married Anne Boleyn, an event which was quickly followed by the publication in Flanders of a threat of excommunication from Rome. After this the Act of Appeals was passed, forbidding appeals from the English ecclesiastical courts to Rome, and Cranmer, in a court at Dunstable, declared the marriage with Catherine null and void. In the following year (1534) the papal authority in England was annulled, and by the Act of Supremacy Henry was declared supreme head of the English Church. The next step was a sad one; but it convinced the world that the king was in earnest. Sir Thomas More and Fisher, bishop of Winchester, the noblest champions of the old faith, two of the best and noblest Englishmen of the time, were executed for refusing to accept the Supremacy Act (1535). Such an event produced a deep sensation in Europe, but it was decisive; when the pope drew up the Bull of Deposition in 1536, which, however, was not published till 1538, the rupture with Rome was complete. In the same year (1536) the first Articles of religion, ten in number, were drawn up; in effect they were a great simplification of the old creed, though they gave little encouragement to Lutheranism. At the same time the Act for the dissolution of the smaller monasteries, which was based upon the report of a commission of inquiry, was passed, being the final important measure of the first Reformation parliament. With such events as the abolition of the papal power in England and the dissolution of the monasteries modern England begins; they inaugurate a fundamental change in the national policy and in the structure and habits of society. While the purpose, real or ostensible, of Henry had been merely to marry a younger woman and provide for the succession, he had effected the greatest revolution which England has undergone.

Henry had indeed succeeded in the task to which he had applied himself nine years before; but the enemies he had raised were formidable, and he was destined to many a bitter disappointment. He had excited the hostility of the pope and the emperor; worst of all, he had seriously hurt the feelings and prejudices of a large class of his subjects. The danger of foreign invasion was greatly increased by the discontent both in the north and west of England, where the love of use and wont in the church and in the national habits was strongest. The death of Catherine had indeed greatly relieved him, as it made reconciliation with the emperor practicable, and deprived the English opposition of a common centre. The rising in Ireland was suppressed without much difficulty, but the discontent in the north which broke out in the Pilgrimage of Grace was a formidable danger (1536). It was averted more by skilful statesmanship on Henry's part than by open show of force. The opposition in the west was nipped in the bud by the execution of its leaders, the marquis of Exeter and Lord Montague (1538). These measures of the king and of his minister Cromwell sometimes appeared cruel and unjustifiable, but they kept the country united; Charles was con-

vineed of the futility of an invasion; and the thunderbolts of the pope fell harmless to the ground. In all this crisis, when a wrong step or the appearance of vacillation might have occasioned a religious war, in which the conservatism at home would have been seconded by the armies of Spain, the energy and the commanding sagacity of Henry did more than aught else to save the country. To him the praise is chiefly due that this great revolution was comparatively free from blood and havoc.

Henry had defied the emperor and the pope, and he had suppressed the conservative Catholic discontent at home with a high hand; but he was never disposed to be a Protestant. Instead of following the lead of the advanced Reformers he impressed upon the English Church his own moderate and substantially Catholic theology. At thirty he had defended the seven sacraments against Luther; he was thirty-six when he took up the question of divorce, and he was forty ere his relations to the pope had hardened into alienation and hostility. All his life he was orthodox from conviction as well as from traditional assent. Such a man could not be a revolutionary in theology. He repressed with a firm hand all excess in innovation, showing equal aversion to the iconoclastic mob and to iconoclastic preachers. The bill of the Six Articles, passed in the same year that saw the final dissolution of the monastic system of England, was the most remarkable exemplification of this spirit of Henry. It also proves that innovation in theology was a new thing to the mass of the English nation, and its penalties too clearly illustrate the fact that religion was not considered an individual and private matter, but a national interest, the violation of which was a capital offence. It is to the honour of Henry that the victims of the Bloody Statute were so few. Five hundred arrests were made by the eager Catholic party in a single fortnight after the passing of the bill; but the king interposed in time, and only twenty-eight suffered under the statute during the whole reign.

In the meantime Henry had been less fortunate in the matrimonial scheme which had been the occasion of all the changes and dangers we have noted. A few months after the death of Catherine, Anne Boleyn was sent to the scaffold. Anne may have been guilty of the crimes laid to her charge, but Henry himself had taught her to cast aside all feminine reserve and self-respect, and his fickle heart had been captivated by another, long before the disclosures which were the ground of her death. Henry married his new love, Jane Seymour, the day after the execution of Anne (1536). The birth of Edward in the following year gratified the king's desire for a male heir; but the early death of Jane left him again without a queen. After an interval of more than two years Cromwell undertook to procure a suitable wife at the Protestant courts of Germany; but his ruin was not less complete than that of his patron Wolsey on a similar occasion ten years before. Anne of Cleves found no favour in the king's eyes; she was divorced and pensioned off, while the enemies of Cromwell succeeded in sending him to the scaffold. Anne's place was occupied by Catherine Howard, till she, really guilty, was also executed (1542). For his sixth and last queen Henry married (1543) Catherine Parr, who proved a patient wife and an excellent nurse. During the last few years of Henry's reign home affairs and the question of the religious revolution ceased to be the exclusive subject of interest. England and the neighbouring powers were constrained to acquiesce for the time being in Henry's arrangement of things. Even the emperor cultivated his alliance. His foreign politics ended very much as they began—with a war against Scotland and France. The former arose out of certain border quarrels; the Scots were beaten at Solway Moss, but defeated an English force at Ancrum Moor. After the death of James V.

Henry's course was to arrange a marriage of the infant queen of Scots with his own son Edward. The plan failed through Henry's self-will, and Scotland was ravaged to no purpose. The war with France (1543-46) was equally fruitless. Its chief feature was a threatened invasion by a formidable French fleet, which for some time was master of the Channel.

At home the most important point of interest was the struggle between the two factions, Protestant and Conservative, which had now for some years confronted each other—Norfolk and Bishop Gardiner of Winchester being the leaders of the latter, while the queen, Cranmer, and the earl of Hertford, uncle of young Edward, were at the head of the former. Cromwell had already fallen under the machinations of the Conservative party. Cranmer and even the queen were not quite safe from its attacks. The heads of that party now suffered at the close of the reign. Surrey was executed, and Norfolk was saved only by the death of the king. The effect of such measures was to make the prospects of Edward secure by confirming the power of his uncle Hertford.

Henry was anxious to arrange affairs for the accession of his son, as he felt his own life waning away. Though only in his fifty-sixth year he was unwieldy with disease and corpulency, and required to be wheeled from room to room; an ulcer in the leg had troubled him for many years. In this as in so many other respects the contrast between the beginning and end of his career is striking: the young athlete is transformed into a helpless invalid; the joviality, the enthusiasm, and the unanimity of his earlier reign gave place to a long period of gloom and contention, repressed only by the savage and imperious hand of the king. He died on the 28th of January 1547.

The character of Henry has long been a stumbling-block to historians, and will always be a puzzle to such as classify mankind under the two heads of good and bad without recognizing the intermediate gradations to which the vast majority belong. To many it is all the more inexplicable, because the contrast between his youth and declining manhood is so apparently complete. Yet it was a perfectly consistent, though a mixed character, and the later phases of it are only a natural development of the earlier. He was always strong-willed to excess, capricious, and fickle, with the sensuous part of his nature predominating. In his youth his baser tendencies were controlled by his love of popularity, his regard for his excellent wife, his own sense of duty, and the vigorous animal spirits which found congenial play in physical exercise and in foreign war. In his maturer years he was more self-reliant and therefore less dependent on popularity; after losing his regard for Catherine he fell into baser companionship; as his health began to fail, his boisterous spirits declined. Worst of all, his constitutional fickleness took the form of disloyalty to his successive wives, and to his friends and ministers. In the time of Henry there was no acuter man than Sir Thomas More. His verdict may be accepted as final on this aspect of the king's character. In the height of his favour with the king, after walking an hour with him in the garden at Chelsea, the king holding his arm about his neck, More confessed that he had "no cause to be proud thereof, for if my head would win him a castle in France it should not fail to go." Such may have been the repulsive side of Henry. Much more important, however, than the consideration of his personal character is the question as to the nature and tendency of the historic work in which he took the initiative. Was that the outcome merely of misguided self-will concealing itself under the guise of duty, or was it the true and durable expression of the claims and aspirations of the time? The passions of Henry had certainly too much to do with it; the work he did was, like his character, mixed with baser elements. But the best answer to such

a question is to be found in the modern history of England. That history in its progressive spirit, in its gradual approximation to a sounder and better state of society, and in its liberal openness to the influence of truth, is only the continuation and development of the work of Henry. In his rupture with the pope, in his abolition of an idle and antiquated monasticism, and in his endeavour to establish a purified and simplified Catholicism as the permanent creed of England, he was fighting on the side of truth and light and progress. The English Reformation was too much alloyed with baser elements to serve as an ideal example of a great historic change; yet it succeeded better than any other in appropriating the good both of the old and the new, in avoiding a violent rupture with the past, in keeping the nation unanimous, and in escaping those fatal religious wars which desolated Europe for nearly a century and in Germany delayed the progress of civilization for a century more. This desirable consummation was due first of all to Henry, whose sagacity and unflinching resolution baffled the enemies of reform both at home and abroad, who repressed the hasty movements of either fanatical extreme in England, and who, with his real reverence for the teaching of the past, had a hearty contempt for its abuses. He was no hero, no ideal man or king; he shared fully in the coarseness and indelicacy of the age; he was fickle in his personal attachments, and did not shrink from destroying those who crossed his plans; but he had a real and lofty sense of his duty as a king; he had a true insight into the men and things he had to deal with, and helped to lead the country into a new era.

HENRY I. (876-936), German king, was born in 876 in Saxony, of which his father, Otte, was duke. He distinguished himself in early youth by the courage and energy with which he warred against the Slavonic tribes to the east of his native duchy. Otte, who died in 912, appointed Henry his successor, not only as duke of Saxony but as lord of Thuringia and part of Franconia. Conrad I., stimulated by certain ecclesiastical advisers whom Henry's independent bearing towards the church had deeply offended, resisted the claims of the young duke; but he was ultimately left in possession of all the lands his father had ruled. After Conrad's death Henry was chosen king by the Franconian and Saxon nobles, and he had not much difficulty in securing the acquiescence of the rest of Germany. For some years Letharingia or Lorraine had held an uncertain position between the kingdoms of the East and the West Franks, as Germany and France were then called; but at this time Duke Giselbert, who was an old friend of Henry, quarrelled with Charles the Simple, and transferred his allegiance to the German king. For eight centuries afterwards Lorraine remained a part of Germany. From the time of Louis the Child, Germany had been tormented by the Hungarians, who were still a savage race, and who had the advantage of fighting on horseback while the Germans resisted them on foot. In 922 an Hungarian chief was captured, and his people were compelled to purchase his release by agreeing to a nine years' truce, on condition that Henry should during this time pay an annual tribute. In the northern districts the Germans had hitherto lived for the most part in small villages or on separate settlements. after

the fashion described in the *Germania* of Tacitus. Henry, perceiving that so long as they continued thus exposed to attack they could never be safe, began the building of cities throughout Saxony and Thuringia, and in the other duchies his example was extensively followed. He also trained his vassals to meet the enemy on horseback, thus giving a strong impetus to the movement which resulted in the institutions of chivalry. When his arrangements were complete he tried his new force in a contest with the Danes and with some Slavonic tribes, whom he utterly defeated. In 933 the Hungarians demanded as usual the tribute which had till then been punctually paid, and when it was refused invaded Thuringia with a great army. Henry twice defeated them, and they were so overwhelmed by this misfortune that they did not enter Germany for some years, and were never again seen in the northern duchies. Having thus broken the power of all the chief enemies of his country, Henry took precautions for the future by establishing the marches of Schleswig, of Meissen, and perhaps of Brandenburg. In his home government he acted with great caution and judgment. The dukes had become so powerful that there was some danger of their altogether overshadowing the throne. Instead of directly meeting this peril by forcing them into submission, as was afterwards done by his son Otto, he attached them to his interests by confirming them in many of their rights and by acting as a mediator in their disputes. Towards the close of his life his position was so secure that he resolved to go to Rome and claim the imperial crown. In the midst of his preparations he died in 936 at Memleben, and was buried in St Peter's church at Quedlinburg. He was one of the wisest and most energetic of the German kings, and through his encouragement of municipal life, and his powerful defence of Germany against her foreign enemies, his reign marks an epoch of the highest importance in early mediæval history. By his first wife, Hatburg, he had a son Thankmar, who gave Otto I., his successor, much trouble. After she was put away he married Matilda, the daughter of a Saxon count; and the gentle and noble character of this lady, who was universally beloved, was of essential service to him in his rule.

See Waitz, *Jahrbücher des Deutschen Reichs unter Heinrich I.* (Berlin, 1837; 2d ed., 1863).

HENRY II. (972-1024), Holy Roman emperor, was born in 972. He was the son of Henry the Wrangler, duke of Bavaria, a grandson of King Henry I. In 995 he succeeded to the duchy of Bavaria, and six years afterwards went to Rome with the young emperor Otto III., to whom he rendered important services. When Otto III. died, Henry, as the chief surviving representative of the house of Saxony, took possession of the insignia of the empire, and was crowned German king at Mainz on the 7th of June 1002. Encouraged by disturbances in Germany, a rebellious party of nobles in northern Italy raised Margrave Harduin of Ivrea to the throne of Lombardy; but Henry advanced against them, and, like his immediate predecessors, made himself master of the iron crown. His most determined enemy during the greater part of his reign was Boleslaus II. of Poland. This ambitious and strong-willed prince annexed Bohemia, and during the king's absence in Italy broke into Lusatia and Meissen. Henry hurried back, defeated Boleslaus in 1005, and granted Bohemia in fief to Jaremir, son of the previous duke. Boleslaus, however, continued the war, which was not ended till 1018, when Henry was obliged to conclude peace on terms that were much more favourable to the Poles than he would have voluntarily granted. In the midst of this struggle he had to make war on Adalbero, his wife's brother, who seized the archbishopric of Trèves, and was protected in his claim by another brother of the

empress, the duke of Bavaria. Both were overcome and deprived of their dignities, although Bavaria was ultimately restored to the elder of the two brothers. Henry also put down rebellions in Flanders and Meissen, and he concluded an important treaty with Rudolf III. of Burgundy, whereby after Rudolf's death the country was to be united to Germany. In 1013 Henry went for the second time to Italy, where Harduin had again raised himself to the throne. The usurper was displaced, and in 1014 Henry was crowned emperor at Rome by Benedict VIII., whom he had confirmed in the papal see in opposition to the antipope Gregory. At the request of Benedict the emperor returned to Italy in 1022 in order to drive back the Greeks, who were steadily pressing northwards. In this enterprise he associated himself with the Normans, who thus became one of the most important factors in the political life of Italy. Henry's health, which was always feeble, rapidly declined after this third visit to his southern dominions, and in 1024 he died. He was canonized by Pope Eugenius III., and at a later time his wife, Cunigunde, was also ranked among the saints. It was natural that they should be thus honoured, not only because of their fervent piety, but because the church has rarely had a more splendid benefactor than Henry II., whose ruling policy was to balance the power of the great nobles by increasing that of the spiritual princes. He also founded the bishopric of Bamberg, which was placed under the immediate jurisdiction of the pope, and to which he left by will all his treasures and his magnificent allodial possessions.

See Hirsch, *Jahrbücher des Deutschen Reichs unter Heinrich II.* (Berlin, 1862-75).

HENRY III. (1017-1056), Holy Roman emperor, was the son of Conrad II., the founder of the Franconian dynasty. He was born in 1017, and his father, anxious to make the succession secure and to strengthen the authority of the crown, caused him to be elected German king in 1026, creating him in 1027 duke of Bavaria, and in 1038 duke of Swabia and king of Burgundy. He became the reigning sovereign of Germany in 1039, at the age of twenty-two. Of an upright and resolute temper, he soon made his power felt both in church and state. The policy he pursued was that which had been followed by Otto I. during the early part of his reign: that is, he granted as many of the duchies as possible either to members of his own family or to vassals on whose loyalty he could rely. Duke Gottfried of Lower Lorraine, who laid claim to Upper Lorraine also, was the only prince who gave him serious trouble, and even this impetuous opponent could not effectually resist the great emperor. Henry was as distinguished in his wars as in his home government. Duke Bretislaus of Bohemia, who gave signs of aspiring to an independent position, invaded Poland, plundered its chief cities, and as a mark of his triumph carried away the body of St Adalbert from Gnesen to Prague. Henry proceeded against him in 1041, and forced him to appear in the following year at Ratisbon in penitent's garb, and to accept Bohemia in fief of the German crown. Having settled this difficulty, he began in 1042 a series of campaigns in Hungary, where for the first time he asserted the supremacy of Germany. In Italy he was equally successful, not only maintaining his right to the Lombard crown, but establishing supremacy over the Normans in Apulia and Calabria. At this time the moral condition of the church was regarded with regret and concern by every serious nature, and Henry, who was of a deeply religious tendency, associated himself heartily with the movement for reform which proceeded from Cluny. At a council of prelates in Sutri in 1046, he caused the rival popes, Benedict IX., Sylvester II., and Gregory VI., to be deposed, and raised to the papal see, as Clement II., Suitger, bishop

of Bamberg. Three other German bishops, one after the other, were appointed to the same position; and as all of them were devout men and energetic administrators, they did much to purify the ecclesiastical system of Europe. During their rule the papacy was held in strict subjection to the empire; but the very earnestness with which Henry applied himself to the task of making the church worthy of its mission created grave dangers for the state, since it was improbable that a pope of proud and independent spirit would be content with a subordinate position. The magnitude of the peril soon revealed itself when Hildebrand became pope during the reign of Henry IV., Henry III.'s son and successor. Henry died in the prime of life in 1056 at Botfeld.

See Steindorff, *Jahrbücher des Deutschen Reichs unter Heinrich III.* (Leipsic, 1874).

HENRY IV. (1050-1106), Holy Roman emperor, son of Henry III., was born in 1050, and crowned German king at the age of four during his father's lifetime. After the death of Henry III. in 1056, the government was undertaken by the empress Agnes, the young king's mother. Henry III.'s vigorous rule, while it had secured the prosperity of the nation as a whole, had excited bitter discontent among the great nobles, and immediately after his death they began to make attempts to recover some portion of the independence he had taken from them. Agnes, who was of too refined a temperament to contend with them, sought to win their support by important concessions; and the evil effects of a feeble central authority were soon felt in every part of Germany. At last, in 1062, Anno, archbishop of Cologne, succeeded in gaining possession of the king by enticing him on board a boat on the Rhine. Agnes then resigned her position, and Anno ruled in her stead. He was a harsh, bigoted, and despotic prelate, and excited Henry's bitter hatred by the sternness of his discipline. In Adalbert, archbishop of Bremen, who was of an exactly opposite disposition,—gay, worldly, and good-humoured,—Anno had an influential rival. This prelate was at first entrusted with some share in the training of Henry, but ultimately completely gained his affections and became his sole guardian. In his fifteenth year Henry was declared, in accordance with the Ripuarian Code, to have reached his majority, but the royal authority was really exercised by Adalbert, who aroused the jealousy of the princes both by his splendid style of living and by his opposition to their usurped powers. At a diet held in Tribur he was compelled to yield the first place once more to Anno. Trained under these diverse influences Henry became passionate and wilful; but he was endowed with considerable intellectual gifts, and when thoroughly aroused could pursue an object with unquenchable ardour. In order, if possible, to check the excesses of his private life Anno caused him to marry Bertha, the daughter of the margrave of Susa, to whom he had for some time been betrothed. At first he regarded her with strong dislike; but after she had borne him a son in 1071 she succeeded in gaining his affections, and was afterwards his most trusted friend and companion.

Henry's reign was one of the most troubled in German history. His chief anxieties began in consequence of Otto of Nordheim, duke of Bavaria, being charged with an intention of murdering him. Otto was declared to have forfeited his titles, and his lands were seized and overrun. Supported by Duke Magnus of Saxony he rebelled, but both princes were quickly subdued. A new rebellion was organized by Otto of Nordheim, who suddenly, at the head of 60,000 men, appeared before the Harzburg, a strong Saxon fortress in which Henry resided. He escaped, but he was looked upon so coldly by the princes that he found it expedient to yield nearly all the demands of his enemies.

An opportunity of revenge was, however, created for him by the violence of a body of peasants, who destroyed a chapel connected with the Harzburg and violated the graves of the king's brother and infant son. He had then no difficulty in obtaining an imperial army, and after defeating the rebels at Hohenburg in 1075, he imposed on them his own terms, and seemed to be on the point of asserting the ascendancy which had been exercised by Henry III.

Meanwhile Hildebrand had become pope as Gregory VII., and had already indicated his design of making the papacy supreme over all earthly authorities. Henry appealed to him to degrade those prelates who had associated themselves with the rebels. Instead of responding favourably to the appeal, Gregory called upon the king to answer to certain charges preferred against him by his subjects. Failing to realize how much power the papacy had acquired through the reforms effected by his father, Henry summoned a council of German prelates at Worms in 1076, and declared the pope deposed. The reply was a sentence of excommunication. Henry's adherents so rapidly fell away that a reconciliation with the pope was soon perceived to be absolutely necessary. Escaping from his enemies he crossed the Alps in the depth of winter, accompanied only by his wife and child and by a few faithful attendants. The nobles of Lombardy were not unwilling to take up his cause, but he preferred to hurry forward to the castle of Canossa, where Gregory was residing with his friend the Countess Matilda. There occurred the famous scene in which Henry, the highest of secular potentates, stood for three days in the courtyard of the castle, clad in the shirt of a penitent, and entreating to be admitted to the pope's presence. No historical incident has more profoundly impressed the imagination of the Western world. It marked the highest point reached by papal authority, and presents a vivid picture of the awe inspired during the Middle Ages by the supernatural powers supposed to be wielded by the church.

The ban was removed; nevertheless the German princes elected Duke Rudolf of Swabia as their king, and they were soon openly supported by the pope, who resented Henry's persistent opposition to his great scheme for the deliverance of the clergy from the system of feudal investiture. Henry renewed his sentence of deposition against Gregory, and raised Guibert, archbishop of Ravenna, to the papacy as Clement III. After the death of the anti-king Rudolf in 1080 he went to uphold his rights in Italy, and in 1084 he gained possession of Rome, where Clement III. crowned him emperor. In Germany Count Hermann of Luxembourg had been chosen as successor to Rudolf, and in 1085 he defeated Henry near Würzburg; but in 1087 he voluntarily resigned his position, and soon afterwards died. A third anti-king, Margrave Eckbert of Meissen, also died in 1089; and had Henry had no enemies outside his native kingdom there would then have been peace. But Victor III. and Urban II., the successors of Gregory VII. (who died in 1085), continued to oppose him, and in 1090 he was obliged to proceed to Italy for the third time to support Clement III., his own antipope. Whilst engaged in this struggle he learned that his son Conrad had been induced by the papal party to rebel against him. Stunned by this unexpected blow, the tired emperor withdrew in disgust to a remote fortress, where he remained inactive for several years. In 1096 he recovered his energy, returned to Germany, and by timely concessions managed to overcome the opposition of his leading enemies. A diet at Mainz decided that Conrad had forfeited his right to the throne, and his brother Henry was proclaimed the emperor's successor. Pope Urban II., the antipope Clement III., and Conrad, all died within two years, and Henry had reason to hope that

he would be able to end his life in quiet. But Paschal II., pursuing the policy of his predecessors, once more excommunicated the emperor, who was driven to despair by the fact of his son Henry putting himself at the head of the pope's supporters. The aged monarch, deceived by false promises, fell into his hands, and was detained as a prisoner. He ultimately fled to Liège, where he might still have been able to bring an army together; but in 1106 he was relieved from his heavy cares by death. The bishop of Liège buried him with a splendour becoming his position; but his enemies carried the body to Spire, where it was laid in an unconsecrated chapel; and it was not properly interred until, after a delay of five years, he was delivered from the ban of excommunication.

Henry holds an honourable position in history because, notwithstanding many personal faults, he resisted the excessive pretensions both of the papacy and of the ambitious feudal lords of Germany. He was unable, however, to make good his claims. Centuries passed before the secular power of the Romish see was seriously weakened, and amid the confused struggles of the time the princes obtained secure possession of rights which they had formerly held by an uncertain tenure.

See Giesebrecht, *Geschichte der Deutschen Kaiserzeit* (3d ed., vol. iii., part 1, Brunswick, 1869); Floto, *Heinrich IV. und sein Zeitalter* (2 vols., Stuttgart, 1855); Minckwitz, *Die Busse Kaiser Heinrichs IV. zu Canossa vor dem Papste Gregor VII.* (2d ed., Leipsic, 1875). (J. St.)

HENRY V. (1081-1125), Holy Roman emperor, son of Henry IV., was born in 1081. In 1098, his elder brother Conrad having forfeited his right to the throne by rebellion, he was appointed his father's successor. Six years afterwards he himself rebelled against the emperor, towards whom he played the part of a thorough traitor. The papal party, with which he allied himself, took for granted that when he mounted the throne church and state would be instantly reconciled; but their hopes were disappointed. The main point for which Henry IV. had contended was the right of investing the bishops with ring and staff. When Henry V. succeeded him in 1106, Pope Paschal II. demanded that this right should be given up, but he replied that he could not resign powers which had been exercised by his predecessors, and the loss of which would imply that the ecclesiastical lands of Germany would be removed from secular control. In 1110 he entered Italy at the head of 30,000 men. Alarmed by this display of force, Paschal withdrew his claims, and a day was appointed for the coronation of Henry as emperor. The opposition of the Roman prelates made it impossible for the pope to proceed with the ceremony, whereupon he and his cardinals were made prisoners. Paschal then formally recognized the right of investiture, and Henry received the imperial crown. When the Germans had recrossed the Alps Paschal renounced the treaty he had concluded, and the emperor was excommunicated. As many of the princes were pleased to find this opportunity of rebelling, Germany again became the scene of confused contests like those which had brought misery upon it during Henry IV.'s long reign. In 1116 the emperor went a second time to Italy and drove Paschal from Rome; and after Paschal's death he caused Gregory VIII. to be appointed pope. The extreme papal party, however, selected Gelasius II., who renewed the sentence of excommunication against Henry. The latter returned to Germany in 1119, and at a diet in Tribur succeeded in allaying the hostility of the more important among his enemies. Pope Calixtus II., who succeeded Gelasius in 1119, now found it necessary to offer a compromise; and the controversy between the empire and the papacy was for the time closed by the concordat of Worms, which was concluded in 1122. By this treaty it was agreed that at every election of a prelate the emperor should have the right

of being present, either in person or through a representative, and that the chosen bishop, before being consecrated, should receive his lands and secular authority in fief of the crown. So far the advantage rested with the emperor; but the papacy gained by being recognized as a power which had the right of negotiating with the empire on equal terms, and by the acknowledgment of the claim of the church to nominate its own rulers. Notwithstanding this settlement Germany did not long enjoy peace, for a number of petty wars broke out which Henry was not strong enough to quell. He died at Nimeguen in 1125, and with him was extinguished the Franconian dynasty.

See Giesebrecht, *Geschichte der Deutschen Kaiserzeit* (3d ed., vol. iii., pt. 2, Brunswick, 1869); Gervais, *Geschichte Deutschlands unter der Regierung Heinrichs V. und Lothars* (Leipsic, 1841-42); Kolbe, *Erzbischof Adalbert I. von Mainz und Heinrich V.* (Heidelberg, 1875).

HENRY VI. (1165-1197), Holy Roman emperor, the son of Frederick I., was born in 1165, and received the German crown in 1169. When his father started for Palestine at the head of the third crusade, Henry was made imperial vicar, and he succeeded to the throne after the news of his father's sudden death reached Germany in 1190. He shared the intellectual culture of his time, and was distinguished for the splendour of his political schemes; but he was of a stern disposition, and in order to attain his ends was sometimes guilty of horrible cruelty. Henry the Lion, who had been banished to England by Frederick I., returned to Germany after the departure of the latter for the Holy Land. Henry resisted him, but on becoming the reigning sovereign he concluded peace, and hastened to Rome, where he was crowned emperor in 1191. Through his wife Constantia he had a right to the throne of Sicily; but the Sicilian nobles had made Count Tancred, an illegitimate son of Constantia's brother, king. After receiving the imperial crown Henry advanced against Tancred, and the whole of southern Italy except Naples was quickly in his possession. Before Naples his army was struck by pestilence, and he was forced to return to Germany. There he suppressed various private wars, and compelled Henry the Lion to acknowledge his supremacy. The great ransom which he received from Richard I. of England enabled him to fit out a fine army, and with this he descended upon Italy in 1194, and without much difficulty conquered the Sicilian kingdom. Tancred was dead, but he had left a number of relatives, who were so barbarously treated that the people were seized with terror, and not even a sentence of excommunication which the pope pronounced against Henry could induce any one to express dissatisfaction with his rule. On his return to Germany it was easy for him, with the prestige he had now acquired, to enforce submission; and so great was his authority that, in 1196, he made attempts to secure that the crown should be declared hereditary in his family. He might have succeeded had he lived some years longer; but in 1197 he died at Messina. Before his death he was engaged in checking disorder which had arisen during his absence in Sicily; and he even obliged the Byzantine emperor Alexius to pay him tribute.

See Toeche, *Jahrbücher des Deutschen Reichs unter Heinrich VI.* (Leipsic, 1867); Mücke, *Kaiser Heinrich VI.* (Erfurt, 1876).

HENRY VII. (1282-1313), Holy Roman emperor was born in 1282. He was the son of Henry II., count of Luxembourg, and was elected king in 1308, seven months after the murder of Albert I. He owed his election partly to the fact that he was comparatively unimportant, which led the electors to suppose that under him the powers of the princes would be exposed to no great danger. When he came to the throne Bohemia was subject to Henry of Carinthia, whom the people extremely disliked. The king at once displaced him, and enriched his own family by granting Bohemia, at the request of the Bohemians themselves, to his son John, whose claims were rendered

secure by his marriage with Elizabeth, the daughter of Wenceslaus II. For some time no German king had sought the imperial crown; but Henry, who was of an imaginative temperament, could not forget the splendid dignities to which the wearer of the crown of Germany was entitled. He therefore resolved to revive the traditions which had begun to die out, and with a view to this result did what he could to compose the differences of the nobles and to gain their allegiance. At this time there were signs of rapid progress among the cities, and had a strong king devoted himself to their interests, he might have established his throne on a solid basis. Unfortunately the easiest way in which Henry could obtain immediate power for his plans in Italy was to ally himself with the princes against the cities; and this was in most instances the course which he adopted. His visit to Italy was looked forward to with eagerness by the Ghibellins, whose hopes were expressed in words of glowing eloquence by Dante. He held aloof at first from both the great parties in the state, and was in consequence liked by neither. In 1312 he was crowned emperor in Rome, having previously received the iron crown in Milan. But while he was in Rome, Robert of Naples was there also with a strong army, and in order to obtain adequate support it was necessary for Henry to declare himself on the side of the Ghibellins. He then resolved to conquer Naples, but while advancing on this expedition he died at Buonconvento, on the 24th of August 1313. It was generally believed at the time that he had been poisoned by a Dominican monk, but this is not proved by satisfactory evidence.

See Dönniges, *Acta Henrici VII.* (Berlin, 1840-41); and *Geschichte des Deutschen Kaiserreichs im 14ten Jahrhundert* (Berlin, 1841); Thomas, *Zur Königswahl des Grafen Heinrich von Luxemburg im Jahre 1308* (Strasbourg, 1875); Pöhlmann, *Der Römische Kaiser Heinrichs VII.* (Nuremberg, 1875).

HENRY I. (1005-1060), king of France, son of King Robert and Constance of Aquitaine, and grandson of Hugh Capet, came to the throne in 1031. On his accession his mother, who favoured her youngest son Robert, allied herself with the chief feudal nobles, and drove Henry to take refuge at the court of Duke Robert II. of Normandy. With the duke's help he soon broke up her league. Constance died in 1032, and Henry, by granting him the duchy of Burgundy, secured the goodwill of Robert his brother, who thus became head of the first house of Burgundy. After the death of Robert "the Devil," Henry, who had first supported William the Bastard, in 1053 and 1054, tried to weaken the power of the Normans. Leaguering himself with the count of Anjou, and calling his brother Eudes into the field, he invaded Normandy from Evreux. When, however, Eudes had been defeated at Mortemer, Henry drew back in haste, and left the Normans to themselves. In 1059 he had his eldest son Philip crowned as joint-king, and died in 1060. He was an active prince, with his sword rarely in the scabbard, being little more than a great feudal chief, who enjoyed the feudal pastime of petty war. Henry's acts and character did little to strengthen the monarchy in its relations with its feudal neighbours. His political horizon was very narrow. The Normans were independent of him; with their frontier barely twenty-five miles west of Paris; to the south his authority was really bounded by the Loire; in the east the count of Champagne was little more than nominally his subject. Henry's first wife (if indeed she was more than affianced to him) Maud, daughter (or niece) of Conrad the Salic, died childless; his second, Anne, daughter of Jaroslav, grand-duke of Russia, bore him two sons,—Philip his successor, and Hugh, count of Vermandois.

HENRY II. (1519–1559), king of France, the second son of Francis I. and Claude, succeeded to the throne in 1547. When only seven years old he was sent by his father, with his brother the dauphin Francis, as a hostage to Spain in 1526, whence they returned after the conclusion of the peace of Cambrai in 1529. Henry was too young to have carried away any abiding impressions, yet throughout his life his character, dress, and bearing were far more Spanish than French. In 1533 his father married him to Catherine de' Medici, from which match, as he said, Francis hoped to gain great advantage, even though it might be somewhat of a misalliance. He did not then think that the dauphin would die so soon, and Catherine thereby become queen of France. Italian manners and politics entered with her into France, and long affected the history and fortunes of the country. Henry gathered round him a court which contrasted strongly with that of his father. Francis, with all his grave faults and selfishness, had fostered learning, had treated his people kindly, and had rarely checked even the Reformers. But Henry, under the influence of Diana of Poitiers, headed the strict Catholic movement; the escape of the learned from Paris to Geneva at his accession showed that not merely Huguenot doctrines but Renaissance studies were in peril. His court underwent an immediate change: the old officers were dismissed, and men whom Francis had disliked or banished returned. Immorality did not take flight, for Diana of Poitiers and Catherine de' Medici were at court, but it ceased to be gay and bright; men must be grave and severe, even in their vices. At first Diana of Poitiers and the grim old soldier Anne of Montmorency swayed the king; later, the two brothers Francis, duke of Guise, and Charles, cardinal of Lorraine, rose to power, with the marshal St André; everything was done and given through one or other of these men. Catherine de' Medici was as yet completely in the background.

The final union of Brittany with France marks the opening year of the reign. In 1548 Henry won a great diplomatic triumph over the ministers of Edward VI. of England, by getting possession of Mary queen of Scots, then only six years old; he had her educated in France, and eventually married to his son the dauphin Francis. In 1549 he appeared in Paris for the first time, and marked his presence by a great burning of Calvinists; and soon after he claimed back Boulogne, which had been promised to Francis I. by Henry VIII. After a successful campaign, he made the English Government, then extremely weak, cede Boulogne, and Henry entered the place in May 1550.

Hitherto he had not come into collision with Charles V.; the time was now approaching when he would enter into contest with him, and permanently advance the borders of his kingdom, while he inflicted a great blow on the emperor. Though early in his reign he had dealt with the German Protestants, and with the Ottoman power, he had taken no active steps; now the league of German princes, headed by Maurice of Saxony, offered an opportunity not to be missed; Henry made a compact with the Swiss and Turks, and concluded a secret treaty (September 3, 1550) with the German princes; in 1552, by the league of Chambord, he undertook to seize the three bishoprics,—Metz, Verdun, and Toul. And so while Maurice drove the emperor from Innsbruck, Henry sent Montmorency into Lorraine. The bishoprics were won almost without a blow, and Henry was acknowledged as "avenger of Germanic liberty"; an attempt on Strasburg failed. After the siege of Metz by Charles V. in the winter of 1552–53, this district, French-speaking, though feudally under the empire, remained in

French hands,—Metz till 1870, Toul and Verdun to this day.

In 1556 Henry, supporting the anti-Spanish policy of the "Theatine" pope, Paul IV., again made war with Spain. Francis of Guise was sent early in 1557 into Italy to oppose the duke of Alva. Anne of Montmorency went to the northern frontier; Gaspard of Coligny, who commanded in Picardy, was ordered to begin hostilities. These led to the disastrous battle of St Quentin, in which the French were utterly defeated (August 10, 1557); it was followed by the fall of the town, at that time the chief bulwark of France to the north. Francis of Guise, recalled in haste from Italy, redressed the balance at the expense of England by the capture of Calais (January 1558), and the triumph of the house of Guise seemed complete when Mary Stewart was married to the dauphin in the same year; their niece, with her claims on the Scottish and English crowns, would now ascend the throne of France. The defeat of the French at Gravelines, the desire of Montmorency to escape from captivity, the wish of the High Catholics to have leisure to extirpate heresy, the sympathy of Philip with that aim, the accession of Elizabeth of England—all these things made peace necessary, and the treaty of Cateau Cambresis (April 1559) closed the war. As a sequel to the peace high feast was held at Paris to celebrate the marriage of Henry's two daughters; in a tournament he received his death-wound from the captain of his Scottish guards, Montgomery. So ended Henry II., in his forty-first year. Handsome, brave, and cold, he left little mark on his age; he is all but forgotten in the stormy days which followed. By Catherine de' Medici he had ten children, three of whom succeeded to the throne,—Francis II., Charles IX., and Henry III. The legislation of his reign was slight; he reduced the number of secretaries of state to four, and arranged their functions afresh; he issued an edict in behalf of a better coinage reserved to himself the exclusive sale of salt, and permitted the foundation of the university of Rheims. In 1555 we find the first French Reformed churches established at Paris; these were quickly followed by others. The reign saw the close of the struggle between the crowns of Spain and France.

HENRY III. (1551–1589), king of France, third son of Henry II. and Catherine de' Medici, succeeded to the throne of France in 1574. In his youth, as duke of Anjou, he was warmly attached to the Huguenot opinions, as we learn from his sister Margaret of Navarre; but his unstable character soon gave way before his mother's will, and both Henry and Margaret remained as choice ornaments of the Catholic Church. Henry won two brilliant victories at Jarnac and Moncontour (1569), and thereby attracted the eyes of the Polish nobles, who elected him their king in 1573. He went to Warsaw, but, on the death of his brother Charles IX. in 1574, came back to France and assumed the crown. He returned to a wretched kingdom, torn with civil war. Now began that "reign of favourites" which has made his career a byword. His mother, ever balancing between parties, first favoured the favourites, then went with the Huguenot chiefs. In these days the famous League was organized (see FRANCE, vol. ix. p. 562), and Henry declared himself its head in 1576. He took but a feeble part in the sixth and seventh civil wars, and was little in earnest till, in 1584, the death of his younger brother, Francis, duke of Anjou, made Henry of Navarre next heir to the throne, and excited to the utmost the fierce passions of the Guises and the League. The

Parisian development of the League under the "sixteen" (1585), with its devotion to Henry, duke of Guise, and its determination to exclude the heretic of Navarre, to depose the wavering Henry III., and to make Cardinal Bourbon king,—this, as well as the menacing attitude of Philip II. of Spain, forced Henry III. to draw towards his distant cousin Henry of Navarre. And so he was driven to desperation by the commanding position assumed by the house of Guise; and in 1588 Henry of Guise and his brother the cardinal were assassinated by his orders. Henry III. now found himself powerless; early in 1589 he again joined Henry of Navarre, and with him laid siege to Paris. There he was murdered by one Jacques Clément, a priest. With Henry III. ended the direct line of the house of Valois. In his young days he had been enthusiastic for learning and the new religious opinions; as he grew older he grew worse; and the last of the sons of Catherine de' Medici was perhaps the most debauched of the kings who hitherto had sat on the throne of France.

HENRY IV. (1553-1610), king of France, was born in the castle of Pau in 1553, being son of Antony of Bourbon, king of Navarre and duke of Vendôme, and Jeanne of Albret. By his father he was tenth in descent from Saint Louis, and only a very distant cousin to his predecessor, Henry III. His mother, a grand and noble lady, brought him up as a Calvinist. His education was rough and hard, and fostered that originality of character which so marked his life; his military training was under the great captain, Gaspard of Coligny. In 1571 he was wedded to the daughter of Catherine de' Medici, Margaret of Valois; and on his mother's death in 1572 he became king of Navarre.

The massacre of St Bartholomew found him in Paris; but his life was spared on his making a profession of Catholicism, which lasted till he succeeded in escaping from court in 1575. Thenceforward he became acknowledged head of the Huguenots, and by his dashing bravery kept life in their dispirited forces. No man was better fitted for such work; he had all the qualities of a guerilla leader, though he was not a great general. His success at Coutras (1587) and the joyousness and generosity of his character endeared him to his followers, while it secured the respect even of his opponents. After the death of Henry III. he was recognized as king of France by only a portion of the army then besieging Paris (August 4, 1589); the Catholic "Politiques" in the army stood aloof and disbanded; the Huguenots formed the only sound nucleus of his power. At Arques (1589) and Ivry (1590) he brilliantly defeated the Leaguers, and resumed the siege of Paris; Alexander of Parma, however, prevented him from taking Rouen (1592); much less could he take Paris. Finding affairs hard, and desiring to be a king and not a guerilla-captain, in 1593 Henry allowed himself to be converted to Catholicism. By this step he struck a deadly blow at the League and made powerless the intrigues of Philip II. For between the fanatical Catholics on one side and the Huguenots on the other lay the great bulk of Frenchmen; the "Politique" party had become more and more powerful, until at length it was felt to be the true national party. The only thing which kept it from Henry was the difference of faith; that barrier removed, all France at once joyfully accepted him as king. The Leaguers became almost a foreign body; the Huguenots gloomily accepted his triumph, bought, as they held, at cost of principle. After the battle of Fontaino-Francaise in 1595

the Spanish and Leaguers were driven out of Burgundy, and the recovery of Amiens from the Spaniards in 1596 secured Picardy and the northern frontier. The *Satire Ménippée*, published in 1593 and 1594, had already condemned the Leaguers as hirelings of the Spanish king; and in April 1598 by the edict of Nantes Henry assured their position to his old Huguenot followers, while by the peace of Vervins (May 1598) he ended the Spanish war, and took from the League its last source of strength.

After 1598 the energies of Henry IV. were given to the restoration of his country, which in nearly forty years of civil war had suffered terribly; the organizing genius of Maximilian of Bethune, duke of Sully, restored the finances; agriculture, manufactures, and commerce made marvellous advances. Henry also upheld the authority of France; in 1601 he acquired Bresse, Bugey, and Valromey from Savoy. He supported the Netherlands against Spain, and he was preparing a great army, which, in combination with the Dutch under Maurice of Nassau, was to interfere in the tangled Cleves-Juliers question, when he was assassinated by Ravallac on the 14th of May 1610. For his character see FRANCE, vol. ix. p. 566.

Henry IV. left no children by his first wife Margaret of Valois; by his second, Marie de' Medici, he had three sons and three daughters,—Louis, who succeeded him as Louis XIII.; a child who died in 1611; Gaston, duke of Orleans, the meanest of the race; Elizabeth, wife of Philip IV. king of Spain; Christine, wife of Victor Amadeus, duke of Savoy; and lastly Henriette Marie, queen of England, spouse of Charles I. He also left behind him several natural children, of whom the most celebrated was César, duke of Vendôme, son of the famous Gabrielle d'Estrées.

HENRY I. (1512-1580), king of Portugal, born at Lisbon, January 31, 1512, was the third son of Emanuel the Fortunate, was destined for the church, and in 1532 was raised to the archiepiscopal see of Braga. In 1542 he received the cardinal's hat, and in 1578 when he was called to succeed his grandnephew Sebastian on the throne, he held the archbishoprics of Lisbon and Coimbra as well as that of Braga, in addition to the wealthy abbacy of Alcobazar. As an ecclesiastic he was pious, pure, simple in his mode of life, charitable, and a learned and liberal patron of letters; but as a sovereign he proved weak, timid, and incapable. On his death in 1580 after a brief reign of seventeen months the male line of the royal family which traced its descent from Henry, first count of Portugal (c. 1100), came to an end; and all attempts to fix the succession during his lifetime having ignominiously failed, Portugal became an easy prey to Philip II. of Spain.

HENRY I. (c. 1207-1217), king of Castile, son of King Alphonso "the Noble," by Eleanor, daughter of Henry II. of England, succeeded his father in 1214, and was killed by the falling of a tile in 1217, after a reign of only two years and nine months. He was succeeded by Ferdinand III., son of his sister Berenguela.

HENRY II. (1333-1379), king of Castile, surnamed *el Bastardo* or *de la Merced*, was one of the six illegitimate sons of King Alphonso "the Avenger," and consequently half-brother to Pedro the Cruel, who legally succeeded to the throne of Castile in 1350. His mother was Leonora

de Guzman. The extraordinary series of cold-blooded murders which earned for Pedro his unenviable surname encouraged Henry, then known as count of Trastamara, to lead repeated rebellions, in which, with the aid of the French under Du Guesclin, and in spite of the opposition of the English under the Black Prince, he was ultimately successful in 1369. He immediately proceeded to direct his arms against the most formidable of his numerous enemies, King Ferdinand of Portugal, and by four campaigns, during the last of which he forced his way to the very gates of Lisbon (March 1373), succeeded in establishing a favourable peace. At the same time he entered into a treaty with the king of Navarre, which subsisted, however, for only three years; in 1375 friendly relations with the king of Aragon were formed, which were cemented by the marriage of the daughter of the latter to Don Juan of Castile. The reign of Henry II., which was devoted rather to defensive than to aggressive warfare, was not marked by any of the usual exploits against the Moors, but it is distinguished in the annals of Castile by some noteworthy improvements in legislation and reforms in the administration of justice, sanctioned in the cortes of Toro in 1369 and 1372; and Spanish historians also mention with special pride the defeat of the English by the Spanish fleet at Rochelle in 1372. Henry died, of poison it is supposed, on May 30, 1379, and was succeeded by his son John (Juan) I.

HENRY III. (1379-1406), king of Castile, surnamed *el Doliente* (the sickly), succeeded his father John I. in 1390, when only eleven years of age. During his minority, the question of the regency not having been very clearly settled by his father, the kingdom was in a constant state of disturbance, bordering upon civil war; unable to satisfy the rival claims of Don Fadrique, Don Alonso, and the archbishop of Toledo, Henry at last resolved, minor as he was, to take the reins of government entirely into his own hands (1393). By energetic measures he succeeded within two years in quelling the turbulence of his nobles, in establishing his own popularity with the body of the people, and thus in effecting the pacification of his kingdom. The only foreign war during this reign was that with Portugal, which terminated in the peace of 1399; a great expedition against the kingdom of Granada, for which extensive preparations had been made, and for which large grants from the cortes held in Toledo in 1406 had been obtained, was brought to an abrupt termination by the death of Henry at that city on December 25 of the same year. It was during this reign that the sovereignty of the Canary Islands was assumed by Castile; and an interesting indication of at least a widening interest in foreign affairs was afforded by the mission of a solemn embassy to Tamerlane in 1401. Henry III. was succeeded by John II., his eldest son by Catherine of Lancaster, whom he had married in 1393. See Davila, *Historia de la Vida y Hechos del Rey Don Henrique Tercero de Castilla* (1638).

HENRY IV. (1425-1475), king of Castile, surnamed *el Impotente* (the impotent) and sometimes *el Liberal* (the spendthrift), the eldest son of John II. by his first wife Maria of Aragon, was born at Valladolid on January 6, 1425. As prince of Asturias he took a prominent and generally an unfilial part in most of the disturbances of his father's reign; in 1445 a pitched battle between the king and the prince was prevented only at the last moment by the intervention of the clergy and some of the nobles; and peace was not finally secured until 1450 when Pope Nicholas V. issued his bull of excommunication against all those in the peninsula who, by perplexing the affairs of the sovereign, were disastrously helping the cause of the infidels. In 1440 Henry had in accordance with a treaty signed in 1436 been

united to Blanche of Aragon; but this marriage, which had not been happy and which had given cause to many scandalous reports, he dissolved in 1453 shortly before his accession to the throne on his father's death in July of that year. He began his reign with a great show of energy against the Moors; but the boldness of his intentions contrasted strangely with the feebleness of his execution; and the unsatisfactory character of the results attained tended greatly to bring to a head the discontent which his indolent inattention to home affairs, his reckless extravagance, and the disorders of his private life had not failed to create. In 1465 occurred at Avila the extraordinary scene, so often described, of the king's deposition in favour of his brother Alphonso; this was followed in 1468, shortly after Alphonso's death, by the election of his sister Isabella, who, however, declined to accept the proffered crown. In the same year Henry was forced to repudiate his wife Joanna of Portugal and to disinherit her daughter Juana (la Beltraneja) whom he had unsuccessfully attempted to put forward as also his; and thus the succession became fixed in favour of Isabella, who was married to Ferdinand of Aragon in the following year. Henry died at Madrid on December 12, 1474.

For the events of the reign of Henry IV., the contemporary authorities are Alonso de Palencia and Diego Henriquez del Castillo, each of whom has left a *Cronica del Rey Don Enrique Quarto*; the best and at the same time the most accessible modern English account is to be found in Prescott's *History of the Reign of Ferdinand and Isabella*, part I., chaps. iii. and iv.

HENRY I. (c. 1210-1274), king of Navarre, surnamed *le Gros*, third count of Champagne, was the youngest son of Theobald I. of Navarre by Margaret of Foix, and succeeded his eldest brother Theobald II. in December 1270. His proclamation at Pamplona, however, did not occur till March of the following year, and his coronation was delayed until May 1273. After a brief reign, characterized it is said by dignity and talent, he died in July 1274, suffocated, according to the generally received accounts, with his own fat. In him the male line of the counts of Champagne, kings of Navarre, became extinct. He was succeeded by his only legitimate child Joanna, born in 1270, by whose marriage to Philip le Bel in 1284 the crown of Navarre became for a time united to that of France.

HENRY II. (1503-1555), or Henri d'Albret, titular king of Navarre, born at Sanguessa in April 1503, was the eldest son of Jean d'Albret by Catherine of Navarre; and on the death of the latter in exile in June 1516 succeeded his parents in all their claims against Ferdinand the Catholic, assuming under the protection of Francis I. of France the title of king of Navarre. After the ineffectual conferences at Noyon (1516) and at Montpellier 1518, an active effort was made in 1521 to establish him in the *de facto* sovereignty; but the French troops which, under André de l'Esparre, had seized the country were ultimately expelled by the Spanish viceroy, the duke of Najera. Henry, who along with Francis was taken prisoner at the battle of Pavia (1525) but afterwards contrived to escape, married Margaret, the only sister of the latter, in 1526, and by her became the father of Jeanne d'Albret, the mother of Henry IV. of France. He died at Pau on May 25, 1555.

HENRY III. of Navarre. See HENRY IV. of France.

HENRY, PRINCE (1394-1460), of Portugal, surnamed "the Navigator," to whose enlightened foresight and perseverance the human race is indebted for the maritime discovery, within one century, of more than half the globe, was born at Oporto, on the 4th of March 1394. His father was João I., under whose reign Portugal first began to recover from her subjugation by the Moors, and to assume a prominent position among the nations of Europe; his mother was Philippa, daughter of John of Gaunt. Prince Henry and his elder brothers, Duarte and Pedro, were sent

out in 1415 on an expedition against the important Moorish city of Ceuta, which, after much hard fighting, they succeeded in taking in one day. All the princes distinguished themselves at the siege, but Prince Henry so pre-eminently that, but for his own entreaties, his father would have knighted him in precedence of his brothers. His renown after this became so high that he was invited severally by the pope, the emperor, and the kings of Castile (Juan II.) and England (Henry V.) to take the command of their respective armies. The prince, however, had set his mind on other and larger plans, involving no less than, the hope of reaching India by the south point of Africa. To this end he had several encouragements: the geographical position of Portugal was in his favour; the large revenues of the order of Christ, of which he was grand-master, provided him with means; and he had contrived to gather important information from the Moors with regard to the coast of Guinea and the populous nations of the interior of Africa. Accordingly in 1418-19 he took up his abode on the extreme south-western point of Europe, the promontory of Sagres, in Algarve, of which kingdom he was made governor in perpetuity, with the purpose of devoting himself to the study of astronomy and mathematics, and to the direction and encouragement of the expeditions which he proposed to send forth. There he erected an observatory, the first set up in Portugal, and at great expense procured the services of one Mestre Jacome from Majorca, a man very skilful in the art of navigation and in the making of maps and instruments, to instruct the Portuguese officers in those sciences. An account has already been given of his principal explorations in the article GEOGRAPHY, vol. x. p. 180 (*q.v.*). At first his efforts seemed to be crowned with little success, and his various expeditions called down upon him much obloquy from the nobles, who complained of such an amount of useless expenditure; but on the prince vituperation fell harmless. The king died in 1438, and the troubles which followed occupied Prince Henry until 1440. In the following year Cape Branco was reached, and in 1443 intercourse was established with negro states in Senegal and Gambia. In 1442-3 Henry VI. of England conferred on the prince the riband of the order of the garter. In 1444-5 were discovered the river Senegal, Cape Verd, Cape St Anne, Cabo dos Mastos, and the Rio Grande. During the later years of his life Gomez and others made important voyages of discovery in Prince Henry's service (see vol. x. p. 180). He died November 13, 1460, in his town on Cape St Vincent, and was buried in the church of St Mary in Lagos, but a year later his body was removed to the superb convent of Batalha. His great-nephew, King Dom Manuel, had a statue of him placed over the centre column of the side gate of the church of Belem. On July 24, 1840, a monument was erected to him at Sagres at the instance of the Marquis de Sá da Bandeira.

The glory attaching to the name of Prince Henry does not rest merely on the achievements effected during his own lifetime, but on the stupendous subsequent results in maritime discovery to which his genius and perseverance had lent the primary inspiration. The sovereigns loyally continued what the prince had begun. The marvellous results effected within a century from the rounding of Cape Bojador in 1483 formed one unbroken chain of discovery, which originated in the genius and the efforts of one man. They were the stupendous issue of a great thought and of indomitable perseverance, in spite of twelve years of costly failure and disheartening ridicule. As Mr Major, in his *Life of Prince Henry*, has justly said, "Had that failure and that ridicule produced on Prince Henry the effect which they ordinarily produce on other men, it is impossible to say what delays would have occurred before these mighty events would have been realized, for it must be born in mind that the ardour, not only of his own sailors, but of surrounding nations, owed its impulse to this pertinacity of purpose in him."

HENRY THE LION (1129-1195), duke of Saxony and Bavaria, son of Henry the Proud, was born in 1129. After the death in 1139 of his father, who had been deprived of his possessions by Conrad III., the bravery and energy of his mother Gertrude and his grandmother Richenza secured to him the duchy of Saxony. Shortly after coming of age he at the diet of Frankfort in 1147 demanded also the restoration of Bavaria, but was refused, upon which, along with his uncle Welf VI., he made an unsuccessful attempt to seize it by force of arms. In 1154 he, however, received from Frederick I. the formal recognition of his claims to its possession, and in 1156 Henry Jasomirgott was compelled to deliver it up to him. Besides distinguishing himself in the wars of Frederick in Italy, Henry now devoted his energies to establishing his power in his own dominions, both by conquest and by encouraging agriculture and trade. He extended the boundaries of Saxony beyond the Elbe by successful battles against the Slavs, founded Munich in Bavaria, colonized Mecklenburg and Holstein, and fostered the growth of Hamburg and Lübeck. His ambitious projects and his arrogant bearing awakened, however, the hostility of several of the secular and ecclesiastical potentates, who in 1166 concluded a league against him at Merseburg, and a stubborn contest of two years' duration ensued, which was finally ended by Frederick in 1169 deciding at the council of Bamberg in Henry's favour. In February 1168 Henry, having previously divorced Clementia of Zähringen, married Matilda, daughter of Henry II. of England; and, elated by such an influential alliance and by the increasing resources of his dominions, he shortly after his return from a pilgrimage to the Holy Land in 1172 began to manifest a tendency to treat the emperor with coldness and to revive the traditional rivalry of his race with the Hohenstaufens. He took no part in the Italian expedition of 1174, and in 1176 his sudden desertion of Frederick in the crisis of his struggle with the Lombard cities resulted in the disaster at Legnano. On Frederick's return from Italy in 1177 Henry was summoned to appear before him at the diet of Worms, and declining to do so he was placed under the ban of the empire, and his lands were divided among other princes. For more than a year he endeavoured to resist the execution of the imperial decree, but he found it necessary at last, in November 1181, to give in his submission to Frederick, who, on condition that he remained three years in England, agreed to reinstate him in the possession of Brunswick and Lüneburg. Having in 1189 refused to accompany Frederick on his crusade, he was again compelled to withdraw to England, but shortly after Frederick's departure he returned, and, concluding an alliance with the archbishop of Bremen, made a second attempt to recover his territories; but, though at first he gained several important victories, he was ultimately compelled in July 1190 to conclude a peace at Fulda, which secured to him scarcely any advantages from the contest. Emboldened by the hostile alliance formed against the emperor Henry VI. in 1192, he again renewed the struggle; but after Richard of England fell into the hands of the emperor in the following year, he found it necessary again to give in his submission; and shortly afterwards a pledge of amity between the two houses was given through the marriage of the eldest son of Henry the Lion to Agnes, niece of Frederick I., and cousin of the reigning emperor. Henry died 6th August 1195 at Brunswick, and was buried in the church of St Blaise. Otto, his second son, became emperor under the title of Otto IV. A colossal statue of Henry was unveiled at Brunswick 4th July 1874. Though ambitious, headstrong, and pugnacious, Henry showed that while he possessed no small skill in the art of war he could appreciate the arts of peace, and he gave

a powerful impetus to the development of many important cities, and furthered with judicious sagacity the material prosperity of his kingdom.

See Böttiger, *Heinrich der Löwe*, Hanover, 1819; Prutz, *Heinrich der Löwe*, Leipzig, 1865; Weiland, *Das Sächs. Herzogthum unter Lothar und Heinrich dem Löwen*, Greifswald, 1866; Philippson, *Geschichte Heinrichs des Löwen*, Leipzig, 2 vols., 1867-8; and the various biographies of Frederick I.

HENRY THE DEACON,—variously called of Cluny, because he was at one time a monk of that rule, of Lausanne, because he is believed to have first appeared as a preacher of repentance there, and of Toulouse, because his later years were passed in that city and neighbourhood,—founder of the anti-sacerdotal sect of *Henricians*, was of Swiss or Italian extraction (his birthplace is unknown), and was born towards the end of the 11th century. About the year 1115 he abandoned the cloister, where he had entered the diaconate, and, burning with righteous indignation against the dead mechanical ceremonialism of the dominant church and the hideous moral corruption of its clergy, began to go about as an itinerant preacher. The neighbourhood of Lausanne was probably the scene of his earliest appearances, but he soon betook himself to France, where the soil had been prepared for him by Peter of Bruis (leader of the Petrobrusians), and where he at once began to attract adherents. About the beginning of Lent in 1116 he asked and received permission of the bishop Hildebert of Le Mans (Cenmani) to visit that city; the fact that he was not only tolerated but received with some degree of honour at this time shows that he had not as yet fallen under serious suspicion of heretical pravity. Soon the extraordinary fascination of his character began to make itself felt; and the rude but convincing eloquence with which he exposed the immorality of the clergy rapidly alienated the people of the town from their spiritual guides; remonstrances and inhibitions by the local ecclesiastical authorities were equally vain; and when Hildebert, who had been absent in Rome, returned to his diocese, he found his episcopal blessing treated with contempt, and was bluntly told by his flock that they had found “a father, a priest, an intercessor, more exalted in authority, more honourable in life, more eminent in knowledge.” From the confused accounts of Henry’s life and labours which have reached us it does not appear that even then he had come forward as the teacher of any new or strange doctrine; his efforts as a reformer of public and domestic morals are chiefly insisted on, especially the measures he took for the reclamation of fallen women, for the encouragement of early and honourable marriage among the laity, and for the promotion of a higher standard of purity among the nominally celibate clergy. It was not as a heretic but merely as a somewhat inconvenient agitator that he was ordered by Hildebert at last to leave Le Mans. We next read of Henry as conspicuously active in Provence, especially after the burning in 1124 of Peter of Bruis, with whose peculiar views he is alleged, upon evidence which has not reached us, to have entirely sympathized. In 1134 he was arrested by the bishop of Arles and taken to the council of Pisa; there he was declared to be a heretic, and condemned to imprisonment. This captivity, however, does not appear to have lasted long. The scene of the third and concluding chapter of the recorded life of Henry is laid at Toulouse, where after ten years of uninterrupted activity with the result complained of by Saint Bernard (*Ep.* 241)—“the churches are without flocks, the flocks without priests, the priests are nowhere treated with due reverence, the churches are reduced to the level of synagogues, the sacraments are despised, the festivals disregarded”—it was found necessary by Pope Eugenius III. to take active measures for the defence of the church. With this view the cardinal bishop Alberic of Ostia was sent as a legate to the disaffected

districts, and with him was associated Bernard of Clairvaux. Their efforts were ultimately successful; Henry died an obscure death in prison about the year 1148, and his sect soon afterwards ceased to have any separate existence.

The original authorities upon this subject are the *Actu Episcoporum Cenomanensium* (“Gesta Hildeberti”), which have been published in Mabillon’s *Anal. Vcl.*, and Bernard’s letter (*Ep.* 241) to Count Ildephonso of St Gilles, written in 1147. From these sources the distinctive tenets of Henry and the Henricians (if distinctive tenets there were) cannot be gathered with any clearness. The probability is that Henry and his disciples had not any definite system of doctrine to oppose to that of the church, but were anti-sacerdotalists pure and simple, “insurgents, who shook the established government, but did not attempt to replace it by any new form or system of opinions and discipline.” See Milman, *History of Latin Christianity*, bk. ix. c. 8; and Hahn, *Geschichte der Ketzerei im Mittelalter* (1845).

HENRY OF GHENT. The scholastic writer generally known by this name was born probably about 1217 in the district of Mude, near Ghent. His family name seems to have been Goethals, but he is always described as Henry of Mude or of Ghent. Little is known of the details of his life. He studied at Ghent and then at Cologne under Albertus Magnus. After obtaining the degree of doctor he returned to Ghent, and is said to have been the first to lecture publicly in that city on philosophy and theology. Like most of the great doctors of the age, he was drawn to Paris by the fame of the university there. In 1247 he is known to have taught at Paris; and he was distinguished by the title of *doctor solennis*. He took an active part in some of the many disputes between the orders and the secular priests, and warmly defended the latter. He died at Tournay, of which place he was archdeacon, in 1293. His most important works, *Quodlibeta Theologica* and *Summa Theologie* have been printed, the first in 1518, the second in 1520. Several other writings remain in MS. Henry of Ghent occupies a somewhat remarkable place in the history of scholasticism. A contemporary of the great Aquinas, he opposed several of the dominant theories of the time, and united with the current Aristotelian doctrines a strong infusion of Platonism and mysticism. Only a few of the salient points of his doctrine can here be given; the line of thinking by which they are reached is elaborate and complex. He distinguishes between knowledge of natural objects and the divine inspiration or intuition by which we cognize the being and existence of God. The first, according to Henry, throws no light upon the second. Individuals are not constituted by the material element in them, but by the fact of their independent existence, *i.e.*, ultimately by the fact that they are created as separate objects. Universals must be distinguished according as they have reference to our minds or to the Divine mind. In the divine intelligence exist exemplars or types of the genera and species of natural objects. On this subject, however, Henry is far from clear; but it deserves notice that he defends Plato against the current Aristotelian criticism, and endeavours to show that the two views are in harmony. In psychology, his view of the intimate union of soul and body is truly remarkable. The body he regards as forming part of the very substance of the soul; through this union the soul is more perfect and complete.

There is a monograph on Henry by Fr. Huet, *Recherches historiques et critiques sur la vie, les ouvrages, et la doctrine de Henri de Gand*; Paris, 1838. See also Werner, *Heinrich von Gent als Repräsentant des Christlichen Platonismus im 13ten Jahrh.*, Vienna, 1878; Stöckl, *Phil. d. Mittelalters*, ii. 738-758; Jourdain, *Phil. de St. Thomas d’Aquin*, ii. 29-46; *Histoire littéraire de la France*, xx. 144 sqq.; also Hanréau, Tennemann, and the general histories.

HENRY OF HUNTINGDON, an English chronicler of the 12th century, born, it is likely, between 1080 and 1090, was the son of an ecclesiastic named Nicholas, who probably held the office of archdeacon of Huntingdon, to which Henry himself afterwards attained about 1120. The celibacy of

the clergy not being enforced in England till 1102, this paternity was considered no disgrace, and our author in several passages of his writings refers to his father with much filial respect. Received as a mere child into the household of Robert of Bloet, bishop of Lincoln, Henry not only continued to enjoy the advantages of its culture and affluence till the bishop's death in 1123, but he also secured the patronage and friendship of Alexander of Blois, who next succeeded to the see. There is reason to believe that he accompanied Alexander to Rome, probably in 1125 and 1144, and it was to him that he dedicated his *Historie Anglorum*, which was issued four times during the author's life, and in the last form came down to the accession of Henry II. (1154). The date of the author's death has not been preserved, but it is probable that the close of his life is approximately marked by the close of his history.

Henry of Huntingdon's *Historie* was first printed by Savile, *Rerum Anglicanarum Scriptores post Bedam* (London, 1586), and it was republished at Frankfort in 1603. Books i., ii., iv., v., and vi. were edited by Mr Petrie for the Record Commission Collection, vol. i., 1848; and the whole work has been prepared for the Rolls Series by T. Arnold, 1880. An English translation by Thomas Forester forms a volume of Bohn's Standard Library (1853). We have besides from Henry's pen an Epistle to Henry I. on the succession of the Jewish, Assyrian, Persian, Macedonian, and Roman kings and emperors (written in 1130); an Epistle to Warin (one of his friends) containing an epitome of the British History of Geoffrey of Monmouth, which he had discovered at Bee in Normandy; and, better known than either, an Epistle to his friend Walter *On Contempt of the World or on Bishops and other Illustrious Men of the Age* (written in 1135, and edited by Wharton in his *Anglia Sacra*, 1691). Nor must Henry's poetical pieces be forgotten, as they speak well for his culture and taste. Two MS. copies of his complete works preserved at Lambeth deserve to be specially mentioned; and the British Museum possesses several important manuscripts of the History. See Wright, *Biogr. Brit. Litt., Anglo-Norman Period*, 1846; Forester's Preface; James Gairdner, *Early Chroniclers of Europe: England* (1879); and Arnold's elaborate introductions.

HENRY, JOSEPH (1797-1878), an eminent American physicist, was born in Albany, the capital of the State of New York, on the 17th of December 1797. He received his education at an ordinary school, and afterward at the Albany academy, which enjoyed considerable reputation for the thoroughness of its classical and mathematical courses. On finishing his academic studies he contemplated adopting the medical profession, and prosecuted his studies in chemistry, anatomy, and physiology with that view. He occasionally contributed papers to the Albany institute, in the years 1824 and 1825, on chemical and mechanical subjects; and in the latter year, having been unexpectedly appointed assistant engineer on the survey of a route for a State road from the Hudson river to Lake Erie, a distance somewhat over 300 miles, he at once embarked with zeal and success in the new enterprise. This diversion from his original bent gave him an inclination to the career of civil and mechanical engineering; and in the spring of 1826 he was elected by the trustees of the Albany academy to the chair of mathematics and natural philosophy in that institution. In the latter part of 1827 he read before the Albany institute his first important contribution, "On some Modifications of the Electro-Magnetic Apparatus." Struck with the great improvements then recently introduced into such apparatus by Mr William Sturgeon of Woolwich, he had still further extended their efficiency, with considerable reduction of battery-power, by adopting in all the experimental circuits (where applicable) the principle of Schweigger's "multiplier," that is, by substituting for single wire circuits, voluminous coils (*Trans. Albany Institute*, October 10, 1827, vol. i. pp. 22, 23). In June 1828 and in March 1829 he exhibited before the institute small electro-magnets closely and repeatedly wound with silk-covered wire, which had a far greater lifting power than any then known. Henry appears to have been the first to adopt

insulated or silk-covered wire for the magnetic coil; and also the first to employ what may be called the "spool" winding for the limbs of the magnet. He was also the first to demonstrate experimentally the difference of action between what he called a "quantity" magnet excited by a "quantity" battery of a single pair, and an "intensity" magnet with long fine wire coil excited by an "intensity" battery of many elements, having their resistances suitably proportioned. He pointed out that the latter form alone was applicable to telegraphic purposes. A detailed account of these experiments and exhibitions was not, however, published till January 1, 1831 (*Silliman's Am. Jour. Sci.*, xix. 400-408). Henry's "quantity" magnets acquired considerable celebrity at the time, from their unprecedented attractive power,—one (August 1830) lifting 750 pounds, another (March 1831) 2300, and a third (1834) 3500.

Early in 1831 he arranged a small office-bell to be tapped by the polarized armature of an "intensity" magnet, whose coil was in continuation of a mile of insulated copper wire, suspended about one of the rooms of his academy. This was the first instance of magnetizing iron at a distance, or of a suitable combination of magnet and battery being so arranged as to be capable of such action. It was, therefore, the earliest example of a true "magnetic" telegraph, all preceding experiments to this end having been on the galvanometer or needle principle. About the same time he devised and constructed the first electromagnetic engine with automatic pole-changer (*Silliman's Am. Jour. Sci.*, July 1831, xx. 340-343; and Sturgeon's *Annals Electr.*, 1839, iii. 554). Early in 1832 he discovered the induction of a current on itself, in a long helical wire, giving greatly increased intensity of discharge (*Silliman's Am. Jour. Sci.*, July 1832, xxii. 408). In 1832 he was elected to the chair of natural philosophy in the New Jersey college at Princeton. In 1834 he continued and extended his researches "On the Influence of a Spiral Conductor in increasing the Intensity of Electricity from a Galvanic Arrangement of a Single Pair;" a memoir of which was read before the American Philosophical Society, February 6, 1835 (*Trans. Am. Phil. Soc.*, v. 223-231, n.s.). In 1835 he combined the short circuit of his monster magnet (of 1834) with the small "intensity" magnet of an experimental telegraph wire, thereby establishing the fact that very powerful mechanical effects could be produced at a great distance by the agency of a very feeble magnet used as a circuit maker and breaker, or as a "trigger"—the precursor of later forms of relay and receiving magnets. In 1837 he paid his first visit to England and Europe. In 1838 he made important investigations in regard to the conditions and range of induction from electrical currents,—showing that induced currents, although merely momentary, produce still other or tertiary currents, and thus on through successive orders of induction, with alternating signs, and with reversed initial and terminal signs. He also discovered similar successive orders of induction in the case of the passage of frictional electricity (*Trans. Am. Phil. Soc.*, vi. 308-337, n.s.). Among many minor observations, he discovered in 1842 the oscillatory nature of the electrical discharge, magnetizing about a thousand needles in the course of his experiments (*Proc. Am. Phil. Soc.*, i. 301). He traced the influence of induction to surprising distances, magnetizing needles in the lower story of a house through several intervening floors by means of electrical discharges in the upper story, and also by the secondary current in a wire 220 feet distant from the wire of the primary circuit. The five numbers of his *Contributions to Electricity and Magnetism* (1835-1842) were separately republished from the *Transactions*. In 1843 he made some interesting original observations on "Phosphorescence" (*Proc. Am. Phil. Soc.*, iii. 38-44). In 1844, by experiments on the tenacity of soap-bubbles, he showed that the molecular cohesion of water is equal (if not superior) to that of ice, and hence, generally, that solids and their liquids have practically the same amount of cohesion (*Proc. Am. Phil. Soc.*, iv. 56, 57, and 84, 85). In 1844 he showed, by means of a thermo-galvanometer, that the solar spots radiate less heat than the general solar surface (*Proc. Am. Phil. Soc.*, iv. 173-176).

In December 1846 Henry was elected secretary and director of the Smithsonian Institution, then just established. While closely occupied with the exacting duties of that office, he still found time to prosecute many original inquiries,—as into the application of acoustics to public buildings, and the best construction and arrangement of lecture-rooms, into the strength of various building materials, &c. Having early devoted much attention to meteorology, both in observing and in reducing and discussing observations, he (among his first administrative acts) organized a large and widespread corps of observers, and made arrangements for simultaneous reports by means of the electric telegraph, which was yet in its infancy (*Smithson. Report for 1847*, pp. 146, 147). It was the first to apply the telegraph to meteorological research, to have

the atmospheric conditions daily indicated on a large map, and to utilize the generalizations made in weather forecasts, and the first to embrace a continent under a single system,—British America and Mexico being included in the field of observation. In 1852, on the reorganization of the American lighthouse system, he was appointed a member of the new board; and on the resignation of Admiral Shubrick as its chairman, Henry, in 1871, became the presiding officer of the establishment—a position he continued to hold during the rest of his life. His diligent investigations into the efficiency of various illuminants under differing circumstances, and into the best conditions for developing their several maximum powers of brilliancy, while greatly improving the usefulness of the line of beacons along the extensive coast of the United States, effected at the same time a great economy of administration. His equally careful experiments on various acoustic instruments also resulted in giving to his country the most serviceable system of fog-signals known to maritime powers. In the course of these varied and prolonged researches from 1865 to 1877, he also made important contributions to the science of acoustics; and he established by several series of laborious observations, extending over many years and along a wide coast range, the correctness of Professor Stokes's hypothesis (*Report Brit. Assoc.*, 1857, part ii. 27) that the wind exerts a very marked influence in refracting sound-beams. The complex conditions of such acoustic refraction he found to be exceedingly variable and curious (*Report American Lighthouse Board*, 1874, 1875, and 1877). From 1868 Henry continued to be annually chosen as president of the National Academy of Sciences; and he was also president of the Philosophical Society of Washington from the date of its organization in 1871.

Henry was by general concession the foremost of American physicists. He was a man of varied culture, of large breadth and liberality of views, of generous impulses, of great gentleness and courtesy of manner, combined with equal firmness of purpose and energy of action. He died at Washington, May 13, 1878. (S. F. B.)

HENRY, MATTHEW (1662–1714), the author of the well known and justly popular *Exposition of the Old and New Testaments*, was born at Broad Oak, a farm-house on the confines of Flintshire and Shropshire, on the 18th of October 1662. He was the son of Philip Henry, one of the 2000 ministers who were ejected from their livings in 1662 for refusing to conform to the Act of Uniformity. Unlike the majority of his fellow-sufferers, Philip Henry, who through his wife was the possessor of private means, was spared all personal privation or hardship as the consequence of his nonconformity, and was thus enabled to give a good education to his son. Having received his preliminary education from his father and a tutor named Turner, Henry was next removed to an academy at Islington, whence he proceeded to become a student of law at Gray's Inn. His legal studies, however, had not advanced far when he relinquished them for theology, to which he thenceforth devoted himself. In 1687 he became minister of a Presbyterian congregation at Chester, whence in 1712 he was translated to Hackney. Two years later (June 22, 1714), he died suddenly of apoplexy at Nantwich while on a journey from Chester to London. Henry's *Exposition*, the work by which he is now chiefly remembered, is a commentary of a practical and devotional rather than of a critical kind, ranging over the whole of the Old Testament and extending into the New as far as to the end of the Acts. At this point it was broken off by the author's death, but the work was finished by a number of clergymen, whose names are recorded in most editions of the book. In a critical point of view, it may be said to be quite valueless; yet its unflinching good sense, its discriminating thought, its high moral tone, its simple piety, and its altogether singular felicity of practical application, combine with the well-sustained flow of its racy English style to secure for it, and deservedly, the foremost place among works of its class.

Besides the *Exposition*, Matthew Henry wrote a *Life of Mr Philip Henry*; *The Communicant's Companion*; *Directions for Daily Communion with God*; *A Method for Prayer*; and *A Scriptural Catechism*, all of which, along with numerous sermons, have been frequently reprinted, both separately and in complete editions of his *Miscellaneous Works*. His life has been written by W. Tong (London, 1816), by Davis (prefixed to *Exposition*, ed. 1844), by Hamilton (*Christian Biography*, 1853), by C. Chapman (1859), and by J. B. Williams (1828, new ed. 1865).

HENRY, PATRICK (1736–1799), an American statesman and orator, was born at Studley, Hanover county, Virginia, May 29, 1736, the second son in a family of nine children. His father, John Henry, an emigrant from Aberdeen, Scotland, was a nephew of Robertson the historian, and had risen to some eminence in the county, filling the offices of surveyor and presiding magistrate. Patrick Henry was educated at a little school near his home; and, after the age of ten, by his father, who had opened a grammar school at his residence. In early life he showed no marked proficiency in his studies, except perhaps in mathematics, but was noted chiefly for a love of outdoor sports. At fifteen he became clerk in a country store; and at sixteen he entered into partnership as storekeeper with his elder brother, but the business was unsuccessful, and a second attempt at storekeeping ended likewise in failure. Meanwhile the indifference to learning which marked his boyhood was replaced by a love of history, especially that of Greece and Rome; and his habitual indolence was overcome by his admiration for Livy, whose history he thenceforth read through once every year. At twenty-four, by his admission to the bar, Henry entered on the career that eventually brought him fame and fortune, although his income for some years was in keeping with his lack of previous preparation. At twenty-seven he won his first triumph, as counsel for the collector of the county, in what became known as "the parson's cause." His unexpected display of eloquence on the side of the people procured him an extravagant recognition and the title of "the orator of nature." Business poured in upon him, his popularity concealing his deficiencies; and his success was assured. In 1765 he was elected to the House of Burgesses, where he distinguished himself as the author of certain resolutions against the Stamp Act, the last of which,—providing that "the General Assembly of this colony have the sole right and power to lay taxes and impositions upon the inhabitants of this colony,"—though passed by a majority of only one, was the key-note of the struggle for independence. In 1769 he was admitted to practice in the general court, where he attained eminence in criminal cases before juries. In 1773 he was a member of the "committee of correspondence for the dissemination of intelligence between the colonies." In the following year he was chosen delegate to the Virginia convention, which was the first public assembly to recommend an annual "General Congress," and to the "Old Continental Congress"; but his success there as an orator failed to conceal his defects as a practical statesman. In 1775, in the Virginia convention, he delivered a remarkable speech in moving that the "colony be immediately put in a state of defence," and at the head of a body of militia he forced the royal officials to pay £330 for powder clandestinely removed by order of Governor Dunmore. He was appointed by the convention colonel of the first regiment and commander of all the forces to be raised in Virginia, but a misunderstanding with the "committee of safety" led to his resignation. He was a member of the second Continental Congress of 1775, and of the Virginia convention of 1776, which had been elected "to take care of the republic," the royal governor having fled. They framed a new constitution, and elected Henry the first republican governor, on the first ballot. He was re-elected in 1777 and 1778. In 1780 he became a member of the legislature, where he continued until he was again elected governor in 1784. In 1786 he withdrew through the pressure of debt, having "never been in easy circumstances." In 1787 he was chosen a delegate to the "Federal Constitutional Convention," but did not attend. He had resumed his practice to better his fortunes. In 1788 he was a delegate to the Virginia convention for ratifying the Federal Constitution, which he vehemently

opposed as dangerous to the liberties of the country. In 1791 he declined re-election to the legislature, continuing, "through necessity rather than choice," the practice of the law, but usually in great and remunerative cases only. Finally, in 1794, having not only paid his debts but secured affluence, he withdrew to private life. In 1795 he declined the position of secretary of state in Washington's cabinet, in 1796 the nomination for governor of Virginia, and in 1797 the mission to France, offered by President Adams. In 1799, however, he suffered himself to be elected to the State legislature, where he wished to oppose what he deemed the dangerous doctrine of the Virginia resolutions of 1798; but he did not take his seat, his death occurring on the 6th June. Henry's manners were plain, his temper cheerful, and his habits temperate. His eloquence, of which some fragmentary specimens have become household words among his countrymen, was vivid and startling. Almost entirely a gift of nature, it was equal to every occasion, and, with the aid of a clear voice and perfect articulation, it was of marvellous power in bringing his hearers to a quick decision.

HENRY, ROBERT (1718-1790), the author of the *History of Great Britain written on a new plan*, was the son of a farmer, and was born in the parish of St Nibians near Stirling, 18th February 1718. He received his early education at the school of his native parish, and at the grammar school of Stirling, and after completing a course of study at Edinburgh University became master of the grammar school of Annan. In 1746 he was licensed to preach by the Annan presbytery, shortly after which he was chosen minister of a Presbyterian congregation at Carlisle, where he remained until 1760, when he was removed to a similar charge at Berwick-on-Tweed. It was during his stay at Berwick that the idea of his *History* first occurred to him, but the dearth of books and the difficulty of consulting original authorities compelled him to postpone the execution of his design till his removal to Edinburgh, as minister of New Greyfriars, in 1768. The first volume of his *History* appeared in 1771, and the others followed at irregular intervals until 1785, when the fifth was published, bringing down the narrative to the Tudor dynasty. The work was virulently assailed by Gilbert Stuart, but the attack was overdone, and although it for a time hindered the sale, the injury effected was only temporary. For the volumes published in his lifetime Henry realized as much as £3300, and through the influence of Lord Mansfield he was in 1781 rewarded with a pension of £100 a year from George III. In 1784 he received the degree of D.D. from the university of Edinburgh. He died in 1790 before his tenth volume was quite ready for the press. Four years after his death it was published under the care of Malcolm Laing, who supplied the entire chapters v. and vii., and added an index. A life of the author by Sir Henry Wellwood Moncreiff was prefixed to the volume. The novel feature in Henry's *History* was that he combined with the narrative of the great political events of each era an account of the domestic state and social progress of the people within the same period. His researches were conducted with great care, and his work embodies much novel and curious information; but the comprehensiveness of his plan, and the limited character of the historical sources then available, greatly militated against the accuracy of his narrative. Notwithstanding also that the work is well arranged, and written with clearness and simplicity, its defects as an authority are not compensated for by any peculiar excellences of style, by originality or vigour of reflexion, or by any special skill in the delineation of character.

HENRY, WILLIAM (1775-1836), a distinguished chemist, son of Thomas Henry, an apothecary and author of some works on chemistry, was born at Manchester, December 12, 1775. After completing his education at an academy in Manchester, he was for some years private secretary to a physician, and in 1795 he began the study of medicine at the university of Edinburgh. Prudential considerations compelled him, however, to interrupt his studies at the conclusion of his first session, and he did not resume them till 1805, two years after which he received the diploma of M.D. For some time he practised as a physician in Manchester, but on account of delicate health, caused by an accident, he was ultimately compelled to retire from his profession. He nevertheless carried on his original researches in chemistry, for which he found great facilities in connexion with his father's business, and from 1797 till his death he continued to enrich the *Transactions* of the Royal Society with contributions on his favourite science, especially in regard to aeriform bodies. His first communication was an attempt, in opposition to Austin, Beddoes, and others, to establish the title of carbon to rank among the elementary bodies, but discovering afterwards a fallacy in his reasoning he corrected it in a subsequent paper. In 1800 he published in the *Philosophical Transactions* his experiments on muriatic acid gas, made with the view of disengaging an imaginary unknown element supposed to be associated with oxygen in the composition of the gas; but after the discovery of the real nature of the acid by Davy he was one of the earliest converts to the new theory. In 1803 he published his elaborate experiments on the quantity of gases absorbed by water at different temperatures and under different pressures, with the result of establishing the law that "water takes up of gas, condensed by one, two, or more additional atmospheres, a quantity which would be equal to twice, thrice, &c., the volume absorbed under the common pressure of the atmosphere." In 1808 he described in the *Philosophical Transactions* a form of apparatus adapted to the combustion of larger quantities of gases than could be fired in eudiometric tubes. In the same year he was chosen a fellow of the Royal Society; and in 1809, for his valuable contributions to the *Transactions* of the society, he was awarded the Copley gold medal. For the next fifteen years he continued his experiments on the gases, making known the results of them from time to time to the society. In his last communication, in 1824, he claimed the merit of having conquered the only difficulty that remained in a series of experiments on the gaseous substances issuing from the destructive distillation of coal and oil, and proved the exact composition of the fire-damp of mines. But though Henry's experiments had reference chiefly to aeriform bodies, his acquaintance with general chemistry is proved by his *Elements of Experimental Chemistry*, a work which combines great literary elegance with the highest standard of scientific accuracy. He had also collected materials for a history of chemical discovery from the middle of last century, but did not live to carry out the project. It is indeed to be regretted that he did not contribute more to the literature of science. His biographical notices of Priestley, Wollaston, and Davy may be regarded as models in that species of composition. At intervals during his lifetime Henry suffered much from neuralgic pains. These became so severe as to render the extirpation of the principal nerves of the hand necessary, but this failed to afford the expected relief; and ultimately the irritation of the whole nervous system deprived him of sleep, and caused his death on September 2, 1836.

HENRYSON, ROBERT (c. 1425-c. 1506), one of the early Scottish poets, and the author of the first specimen of the pastoral poetry of his country, is usually designated schoolmaster of Dufermline; and according to tradition

A Continuation of Henry's History to the Accession of James I., by P. de Anfréws, appeared in 1796. An account of the attack of Albert Stuart on Henry is given in Disraeli's *Calamities of Authors*.

he was the ancestor of the family of Henryson or Henderson of Fordell, in the county of Fife, one of whom, James Henryson, was king's advocate and justice-clerk in 1494. Of the poet's parentage and early history, however, no certain information can be discovered. From various circumstances known about him he must have been born about the year 1425. He seems to have been educated abroad, as his name does not appear in the registers of the university of St Andrews, the only one then existing in Scotland; and from an allusion in one of his poems, his attention was probably given to the study of law. In 1462 his name appears in the list of members of the newly-founded university of Glasgow as "Magister Robertus Henrysone in artibus licentiatus et in decretis Bachalarius." Henryson seems, in addition to teaching, to have practised at Dunfermline as a notary public. His decease in or shortly before 1506 is alluded to by Dunbar, who, in his lament for the "makaris" or poets, says of Death—

"In Dunfermline he hes done roun
Gud Maister Robert Henrysoun."

Of the writings of Henryson that have come down to the present time, his *Testament of Cresseid* may be considered the chief. It was composed as a continuation or supplement to Chancer's *Troilus and Cresseid*, which was one of the most popular poems in the English language. Henryson resumes the story where Chancer leaves off, and completes it by inflicting a suitable punishment on the false Cresseid. This continuation displays so much skill that it has been included in all the early editions of Chancer, as if it had been the work of that poet himself. Another poem, *Robene and Makyne*, though short, is remarkable as the first known specimen of pastoral poetry in the Scottish language, while his *Bluidy Serk* is amongst the oldest examples of ballad poetry. His metrical version of thirteen of the *Fables of Æsop* is perhaps the best known of his works. To each fable is appended an application or moral. In these he alludes to the oppressions of the people and the unsettled state of the country during the feeble reign of James III. His classical *Tale of Orpheus*, though a languid performance, exhibits his familiarity with the scholastic learning of his time. Several of the poems of Henryson have been preserved in the Asloan MS. in the Auchinleck Library, the Bannatyne MS. in the Advocates' Library, Edinburgh, the Maitland MS. in the Pepysian Library, Cambridge, and the Harleian MSS., British Museum. His *Orpheus and Eurydice* was printed at Edinburgh by Chepman & Myllar in 1508. The *Testament of Cresseid* was printed at Edinburgh by Henry Charteris in 1593. The poem of *Robene and Makyne* and the *Testament of Cresseid* were reprinted for the Bannatyne Club in 1824. The *Moral Fables* were printed at Edinburgh by Lekprevik in 1570, at London by R. Smith in 1577, and again at Edinburgh by Andrew Hart in 1621. This last edition was reprinted for the Maitland Club in 1832. A collected edition of the works of Henryson, leaving nothing to be desired, was printed at Edinburgh in 1865, under the editorial care of Dr David Laing.

HENSLOWE, PHILIP, a contemporary of Shakespeare, whose name continues of interest from his intimate association with the history of the theatre during the great dramatist's career. Originally, it would appear, a dyer and afterwards a starchmaker, and ready to turn to any profitable speculation, he probably began his connexion with the stage in 1584 by becoming "joint lessee of the Rose theatre on the Bankside, or of the ground on which it stood." From 1591 to his death in 1616 he was in theatrical partnership with the more famous Edward Alleyn, who in 1592 married his step-daughter Joan Woodward. In 1613 he was appointed sergeant of the king's bear-garden, to take charge of a lion and certain other beasts presented by the duke of Savoy. Henslowe's business diary from 1593 to 1609 has happily been preserved in Alleyn's College at Dulwich, and, though evidently the work of an ignorant man, it is of prime importance for its miscellaneous store of items in regard to the first appearance of plays, the sums paid to the authors, the theatre receipts, and so on. It was edited for the Shakespeare Society in 1841 by J. Payne Collier, who, however, found that the MS. had suffered considerable mutilation at the hands of miscreant autograph hunters since the time when it was employed by its original discoverer Malone. See ALLEYN.

HIENZADA, a district in Pegu division, British Burmah, lying between 16° 49' and 18° 30' N. lat., and between 94° 51' and 96° 7' E. long., with an area of 4047 square miles. It is bounded on the N. by the Promé district, on the E. by the Pegu Yomas, on the S. by Rangoon, Thonkhwa, and Bassein districts, and on the W. by the Arakan Yoma range. Henzada district stretches from north to south in one vast plain, forming the valley of the Irawadi, and is divided by that river into two nearly equal portions. This country is protected from inundation by immense embankments, so that almost the whole area is suitable for rice cultivation. The chief mountains are the Arakan and Pegu Yoma ranges. The greatest elevation of the Arakan Yomas in Henzada, attained in the latitude of Myan-oung, is 4003 feet above sea-level. Numerous torrents pour down from the two boundary ranges, and unite in the plains to form large streams, which fall into the chief rivers of the district, viz., the Irawadi, Hlaing, and Bassein. The forests comprise almost every variety of timber found in Burmah.

The inhabitants of Henzada district in 1876 numbered 501,213. The number of immigrants into the district during the ten years ending 1876 was 90,797. The chief occupation of the people is agriculture. Nearly all the large towns are on the right bank of the Irawadi. The chief towns have populations as follows:—Henzada, 15,307; Kyan-kheng, 8761; Myan-oung, 5859; and Meng-gyi, on the left bank of the Irawadi, 15,770. The staple crops of the district are rice, sesamum, cotton, and tobacco. The total area under cultivation in 1876 was 363,048 acres. The other products are cotton, indigo, oil-seeds, pease and pulses, cocoa and betel nuts, *pin*-vine, &c. The revenue in 1876-77 was £132,733. In 1876 the police force consisted of 409 men.

The district was once a portion of the Talaing kingdom of Pegu, afterwards annexed to the Burmese empire in 1753, and has no history of its own. During the second Burmese war, after Promé had been seized, the Burmese on the right bank of the Irawadi crossed the river and offered resistance to the British, but were completely routed. Meanwhile, in Tharawadi, or the country east of the Irawadi, and in the south of Henzada, much disorder was caused by a revolt, the leaders of which were, however, defeated by the British, and their gangs dispersed.

HEPATICÆ. See LIVERWORT.

HEPHÆSTION, son of Amyntor, a Macedonian of Pella, is celebrated as the friend of Alexander the Great. The two, according to Quintius Curtius (iii. 12), were companions in childhood, but beyond this old-standing connexion we find no evidence of such qualities in Hephæstion as deserved the passionate attachment of Alexander. The king, however, seems never to have been blind to his real character, and to have made a marked distinction between him, as the friend of his private life and his leisure hours, and such men as Craterus, whom he could entrust with important enterprises. We do not hear again of Hephæstion till 334 B.C., when he accompanied the king on his visit to Troy. Many tales are told of the close intimacy subsisting between them; for example, Plutarch says that, when a letter of very delicate and private nature from Olympias was handed to Alexander, Hephæstion according to his custom was reading it over his shoulder, when Alexander without uttering a word took his ring off his finger and pressed it on his friend's lips. In the later campaigns of Alexander in Bactria and India, we find Hephæstion charged with important commands. He was rewarded with a golden crown and the hand of Drypetis, the daughter of Darius and sister of Alexander's own wife Statira (324 B.C.). In the end of the same year he died very suddenly at Ecbatana. Alexander tried to relieve his grief by paying the most extravagant honours to his friend. A general mourning was ordered over Asia; at Babyion a funeral pile was erected at a cost of 10,000 talents; and temples were erected to him as a hero.

HEPHÆSTION, a grammarian of Alexandria, author of a work on Greek metres called *ἔγχειρίδιον περὶ μέτρων*. This work is most valuable as the only complete work on the subject that has been preserved. The author is pro-

bably the same as the grammarian that acted as tutor to the emperor Verus about 150 A.D.

HEPHAËSTUS, a word of uncertain derivation but certainly pre-Greek in formation (Kuhn, *Zeitschr.*, v. 214), denotes among the Greeks a god who represents the power of fire and its appliances in the operations of daily life, corresponding to the Latin Vulcan. A clear distinction must be drawn between the Hellenic god and the deity worshipped by the Pelasgic races. Though the word Hephæstus is used by Homer in the sense of fire, yet in the Hellenic god no elemental idea is at all prominent. The Hellenic religion had raised itself far above such conceptions of the divine power, and its gods were moral powers. Zeus, the ruler of the world, whose will, according to the finest Hellenic conception, is fate, is surrounded by a court in which Hephæstus appears as the divine artificer, an object rather of laughter than of respect to the other gods. No worship was paid him, for his altar at Olympia seems not to have been an ancient institution. The fire of the hearth, as the centre of family and city unity, is now personified under a purely Greek name, Hestia; but here again it is not the elemental but the moral conception that is the predominant idea in the goddess (see HESTIA). The similarity between the divine artificer of the Greeks and the Finnish Ilmarine or the German Wieland, who has degenerated finally into the Wayland Smith of Scott's *Kenilworth*, has been often pointed out, and the starting-point of them all is the smith who makes the new sun every morning (see Manhardt, *Zeitschr. f. Ethnol.*, 1875, p. 221). The round disk of the sun has in poetic treatment become the shield of Achilles, whose fabrication is the great deed of Hephæstus in the *Iliad*. This artificer is naturally represented as married to the dawn, Aphrodite or Charis (see GRACES), as Wieland marries the Swan-maiden; and the girdle of Aphrodite which Hephæstus made is the halo of rays that heralds the rising sun. All wonderful works seem to be attributed to the divine smith; in particular the house of the gods has been made by Ilmarine and by Hephæstus; and they also, like Wieland, have made metal figures that move and almost equal living beings. In general the art of working metals by the hammer is under his patronage—a fact which points out this art as one of the very oldest known to the race (Conze, *Götter- und Heroen-Gestalten*, s.v.). In local traditions a set of elfish creatures like the Idææ Dactyls or the dwarfs in German legend were often put in place of this divine smith. The belief which in Lipara and Strongyle was associated with Hephæstus, that any one that put a lump of iron in a certain spot at night found next morning the article he wished ready made, provided he paid the required price, is in some parts of Germany attached to a corresponding set of dwarfs. An ill-omened character often attached to the works of Hephæstus, as to that of the Telchines or the German dwarfs. Other points in the Hellenic Hephæstus can be explained only by a reference to the worship of the older Pelasgic tribes. When Homer (*Il.*, i. 569) says that he was hurled by his father Zeus down to the earth, the reference to the lightning is unmistakable (Weleker, *Gr. Gött.*, i. 661). Again the weak legs always attributed to Hephæstus remind us of the serpent legs of his son Erichthonius; and serpents occur often as symbols of lightning. Homer (*l.c.*) says that Hephæstus fell on Lemnos, whose inhabitants tended him; he evidently considers that the Hellenic deity was identical with the Pelasgic god. Wherever a Pelasgic race is most certain, there the god is found, associated with the Cabiri: he is the Cabirus *par excellence* (Herod., vi. 138). Among these tribes the power of fire was considered the life-giving and reproductive power of nature, and the deity in whom it was embodied became the chief object of their worship.

Hence on the coins of Imbros an ithyphallic Hephæstus appears. As Greek influence prevailed among the kindred Pelasgic tribes, their native worship survived in the form of mysteries, and their proper gods, whose nature was revealed to the initiated, became in popular tradition heroic or demoniac figures who were the founders of the mysteries (v. HARMONIA, and comp. Lenormant in D'Arenberg's *Dict. des Antiquités*, art. "Cabiri"). This Hephæstus or Cabirus is the lightning that has descended to earth and become there the origin of all life, and according to Pindar (*Fr.* 162) the first man. The original conception, vague and wide like all primitive ideas, is that the heavenly and the subterranean fire are identical with the fire on earth. In both thunderstorm and dawn the fire of the sun is relighted after being for a time extinguished. In both the alternation of light and darkness was the prominent fact. In the thunderstorm the sparks emitted from the sun descend as the lightning to earth. This original power of fire has been developed in various ways: the higher thought of the Greeks rejected such a naturalistic deity as the Pelasgic found congenial, while in Athens, where the Pelasgic element was very strong, Hephæstus occupied a correspondingly high place, and is in close relationship with Athene. In many ceremonies, as the Lampadephoria, they were associated; and at the Apaturia honour was paid to Zeus Phratrius, Athene, and Hephæstus. In the oldest traditions they were perhaps married, and their son Erichthonius was the parent of the Athenian people. When the Hellenic conception of the maiden-goddess Athene prevailed, this connexion was transformed into an unsuccessful attempt of Hephæstus at a union with Athene. But the marvellous birth of Erichthonius is an ancient feature, as it occurs in Vedic tradition (Kuhn, *Zeitschr.*, i. 443).

Small images of Hephæstus stood on every hearth at Athens, and the Amphidromia round the hearth-fire was the rite whereby the newly-born child was adopted into the family. In the oldest Greek art Hephæstus is a bearded man fully clad, carrying a hammer. This hammer, which the Cabirus of Thessalonica carries, is doubtless in its origin, like the hammer of Thor, the thunderbolt or hammer with which was shattered the tower where the sun was hid during the winter darkness. An undignified and comic character is, however, often apparent, when he wears short, workman's clothes, and wants the dignity proper to a god. The ruling type in later art is a bearded man with a certain resemblance to Zeus, wearing a close cap, carrying the traditional hammer, and clad in a short, girt tunic which leaves the left shoulder free. (W. M. RA.)

HERA, a word of which many different derivations have been proposed, is the name of a Greek goddess, corresponding to the Latin Juno, who according to the conventional type is the wife of Zeus and queen among the gods of Olympus. In the literature of the Greeks Hera fills a very conspicuous place—the strong, haughty, and rebellious character, full of intense hatreds and likings, which was associated with her, made her a picturesque and dramatic figure. According to this conception of her, she was daughter of Cronus and Rhea, and at once sister and wife of Zeus. She was always the bitter enemy of all the heroines who were the successive objects of her husband's love, and her persecution of them and of their children often forms the theme of poets from the *Iliad* (xxiii. 119) downwards. This type, which is the familiar one in all literature, had never any real existence in religion; but had been gradually elaborated by poets from the actual deity worshipped in various parts of Greece, and from the legends transmitted to the Greeks from earlier races.

The most characteristic and fundamental point in the worship of Hera is the *ἱερός γάμος*, her marriage with Zeus; and from this any explanation of the conception involved in the goddess must start. Again in Greek legend we learn that a close connexion exists between Hera and the cow, and that probably she was originally thought to have the

form of a cow. These facts at once direct us to the ancient Aryan idea, described in detail by Gubernatis (*Zoolog. Mythol.*, i.), that the divine power as the origin of all life is embodied in a pair of gods male and female, whose fertility leads to the conception of them as a bull and a cow. This pair, the bull and the cow, appear in various fantastic developments in Greek legend. For example, Zeus himself in the form of a bull carries off Europa; and we learn from Hesychius that Europa is an epithet of Hera. Looking at the matter from this point of view, we find that the question so much disputed among mythologers, whether the naturalistic conception out of which the Greek goddess has developed be earth or moon, is a mere matter of words, and that there is no real discrepancy between the two views. The free and vague conceptions of primitive men refuse to be shut into the precise circumscribed terminology of modern thought. Ideas which to us are very different were once expressed by the same root (see Curtius, *Grundz.*, iii. 284, No. 415). Thus we have in the *Rig Veda*, vi. 51, 5, a clear trace of the view so common in all mythologies, whether in the theogony of Hesiod or of the New-Zealanders, that Heaven and Earth are the primitive pair of deities, parents of all existence and first of the gods. This view is of peculiar importance in old Roman religion (*cf.* Schwegler, *Röm. Gesch.*, i. 328, 422, &c.), and also among the older Pelagic tribes of Greece. But this same divine power the primitive Aryans beheld in all the great operations of nature; in each they saw the prototype of all earthly works, and in seeking here the origin of life, they found it in the same divine pair, the bull and the cow. In particular, the various alternations of light and darkness appealed to their minds most strongly, and occupy great part of their mythology. In the transitions between light and darkness, and especially in the struggle between night and day, the idea of a pair is not so prominent; and in legends the marriage of moon and sun does not figure very conspicuously. Yet we sometimes find the marriage of the moon and sun described exactly in the way of this *ἑρὸς γάμος*. In *Rig Veda*, x. 85, it is the type of all earthly marriage (see Weber, *Ind. Stud.*, v. 178). A Slavonic story makes the marriage of moon and sun annual: they part every winter and meet again in the first days of spring; and a Lettish song makes the marriage of moon and sun in spring (Mannhardt in *Zft. f. Ethnol.*, 1875, p. 316). The moon too is often symbolized as a cow. The mystic union takes place in the spring when life returns to the earth, and the voice of the cuckoo is heard in the land. Hence in the legend Zeus, enamoured of his sister Hera, is said to have flown to her in the form of a cuckoo dripping wet, and to have been in pity received into her bosom. In various parts of Greece where traces of the ruder tribes are strongest, there remains a coarser conception of this union, and in the popular accounts the marriage customs of the country are reflected (see Welcker, *Gr. Götterl.*, i. 364 ff.). Lectum in the Trojan Ida and Ocha in Eubœa, on the summits of which this union is placed by the legends of the countries, received their names from it. As we might expect, this idea is too purely naturalistic to form any part of the moral Olympian religion. Hera appears there as the wife of Zeus, but all deeper meaning has disappeared. The old tale remains in the mythological legends, which always clung as a degrading appendage to this religion, and we find it in Homer (*Il.*, xiv. 294) transformed into an incident of the Trojan war. In the popular religion, however, Hera, as first the virgin, then the sacred bride, and finally the lawful wife of Zeus and the patron of all marriage, is a very prominent figure. Every year the festival of Hera was celebrated with special reference to this union in Argos, Samos, Elis, Platæa, and many other parts of Greece. The festival took place in a month named

Γαμηλιών at Athens, *Ἡραῖος* in some other parts of Greece. Hence we have such epithets of Hera as *Νύμφη*, *νυμφενομένη*, *τελεία*, *γαμηλία*; and the bridal veil is one of her most frequent attributes. Hera was married to Zeus in early youth, and knew no other marriage. Hence she is the patron goddess of all married women, the protectress of the sanctity of marriage; and she demands the utmost purity from her votaries. In this respect Hera approaches closely to Demeter Thesmophoros. As the winter is a time of barrenness and separation, so we have in Arcadian, Argive, and Samian legend the angry Hera, the widow Hera, separated from her husband.

Other points in Hera again point directly to the moon. Like all other forms of the moon-goddess (see *HECATE*), she presided over child-birth, and under the epithet *ελεΐθια* was invoked by women in labour. This idea arises from the moon's use as measurer of time and number of the months. Then the epithet became gradually developed as a daughter, or set of daughters, of Hera, named *Eleithyia*. Beauty is another characteristic of all moon-goddesses, and of Hera also. In her festival at Lemnos prizes were assigned after a contest to the most beautiful woman. Large eyes were part of the artistic type, and *βοῶπις* is one of her most constant epithets in literature.

Eubœa, the very word being an epithet of the goddess, was one of the chief seats of the worship of Hera. So in Bœotia, her temples both at Thespie and at Platæa were famous. In the *Iliad*, Argos, Sparta, and Mycenæ are the cities which she specially protects and loves. Argos was always one of the chief seats of her worship, and the Heraion there was one of the chief temples of Greece. At Olympia also was a very ancient temple, the Heraion, the ruins of which have been recently brought to view by the German exploring expedition. At the Lacinian promontory Hera was the patroness of the union first of the Achæan cities and afterwards of a wider circle of the Greek colonies. But the Hera of Samos was perhaps the most famous and most characteristic appearance of the goddess. There the Greek goddess was amalgamated with another, who was worshipped by the kindred tribes among whom the Greeks settled, and who is clearly the same as the Artemis of Ephesus or Clazomenæ; and so on coins of Samos we find Hera standing with the sun and moon on either side of her head, exactly like Artemis on coins of Ephesus.

We find such rude images of Hera as a plank at Samos, or a branch at Thespie. A very ancient statue by Smilis stood in her temple at Samos; the goddess, veiled, stood erect, clad in a long chiton, holding in each of her outstretched hands a *φάλαξ*. In the earlier vase-paintings she is hardly to be distinguished from Artemis. She appears, just like Artemis, carrying torch and bow, and wearing the kalathos or the stephanos; and several figures which others consider to be Artemis, are by Overbeck explained as Hera. In representations of the Judgment of Paris there is often nothing to distinguish her from Aphrodite. Her characteristic symbols are the veil or sceptre, and she often carries a fruit. Numerous vase-paintings, representing a bridal procession, which Förster (*Zeus und Hera's Hochzeit*) believes to represent the *ἑρὸς γάμος*, are by Jahn and Overbeck shown to be an earthly marriage escorted by deities. Overbeck (*Hera*, p. 174) maintains that only three certain representations of this scene exist. The colossal statue by Polycletus in the Heraion at Argos showed her enthroned, wearing the *στεφάνη*, holding in one hand a pomegranate and in the other a sceptre, on the top of which was a cuckoo. There is no evidence to determine what was the character of the face, nor what share it had in determining the ideal type of Hera (Overbeck, *l.c.*, p. 51). The Farnese bust at Naples represents a type more antique than the style of Polycletus. Praxiteles made three great statues of Hera, at Megara, Mantinea, and Platæa. The last, which represented Hera Telea standing, is known to us by many imitations in the Vatican and elsewhere. From the works of these two great artists we may suppose that the highest type of Hera was elaborated in the Athenian school about the middle of the 4th century, and in the famous bust of the Villa Ludovisi it is probable that we have the actual work in which this type was first attained. This bust, which has been often described, and especially by Goethe, was probably once the head of a colossal seated statue.

(W. M. RA.)

HERACLEA, or HERACLEIA (in French, *Héraclée*), the name of several ancient cities in various parts of the area of Greek colonization, so called in honour of Heracles or Hercules.

I. HERACLEA, a city of Magna Græcia, which lay between the rivers Aciris and Siris, not far from the shores of the Gulf of Tarentum, near the site of the modern village of Policoro. It appears to have been a joint colony of the Tarentines and the Thurians, and to have risen after the destruction of the neighbouring city of Siris. That it attained to no small prosperity and became the seat of the great politico-religious assembly of the Italian Greeks is nearly all that can be said of its earlier history. By Alexander of Epirus it was deprived of this privilege in favour of Thurii. Pyrrhus was victorious in its vicinity in the first battle he fought with the Romans, 280 B.C., and two years later the city formed an alliance on advantageous terms with the conquerors. In the time of Cicero it was still comparatively prosperous. The *Tabula Heracleenses*, found at Luce near the ruins of the city in 1753, are two bronze tablets, or rather fragments of tablets, containing on one surface a Greek inscription relating to temple domains and on the other surface a copy of the famous *Lex Julia Municipalis* published by Julius Cæsar in 45 B.C. They are preserved in the Museo Nazionale at Naples, and one of them is distinguished as the *Æs Britannicum* and the other as the *Æs Neapolitanum*. Both inscriptions are given in Mazzeochi, *Commentaria in Regii Herculaneensis Musei aeneas tabulas Heracleenses* (Naples, 1754–55), and the Latin one will be found in Muratori, *Inscriptiones* (vol. ii.), and Haubold, *Monumenta legalia*. See also Savigny, *Zeitschrift für geschicht. Rechtswiss.* (vol. ix.) and *Vermischte Schriften* (vol. iii., Berlin, 1850).

II. HERACLEA, a city of Sicily, at the mouth of the Ialycus (the modern Platani), not far from the promontory now known as Capo Bianco. It was distinguished from the other Heraclæas by the surname of Minoa, which was explained as referring to its foundation by Minos of Crete. Its name frequently occurs in connexion with the Carthaginian occupation of Sicily, and it was in the neighbouring sea that the Carthaginian fleet was routed by Regulus and Manlius in 256 B.C. The Romans introduced a colony.

III. HERACLEA PONTICA, a city on the coast of Phrygia in Asia Minor, easily identified with the modern Bender Ereğli or Ereğli, at the mouth of the Kilidj-su on the Black Sea. It was founded by a Megarian colony, which soon subjugated the native tribe of the Mariandynians, and extended its power over a considerable territory. The prosperity of the city, rudely shaken by the Galatians and the Bithynians, was utterly destroyed by Aurelius Cotta in the Mithridatic war. It was the birthplace of Heraclides Ponticus. The modern town is best known for its coal mines, from which Constantinople receives a good part of its supply. See Pilsberw, *De Rebus Heracleæ*, Brandenburg, 1833; and O. Kammel, *Heracleotica: Beiträge zur alten Gesch. der griech. Colonisation im nördl. Klein-Asien* (Progr. des Gymn. zu Plauen, 1869).

IV. HERACLEA SINTICA, a town in Thracian Macedonia, to the south of the Strymon, the site of which is marked by the village of Zervókhori, and identified by the frequent discovery of local coins.

V. HERACLEA, a town on the borders of Caria and Ionia, near the foot of Mount Latmus, whence it is usually distinguished as the Latmian. In its neighbourhood was the burial cave of Endymion. See Rayet and Thomas, *Milet et le Golfe Latmique*, Paris, 1877.

For Heraclæa Trachinia see ΤΡΑΧΩΝΙΣ, and for Heraclæa Perinthus see ΠΕΡΙΝΘΙΟΣ.

Heraclæa was also the name of one of the Sporades, between Naxos and Ios, which is still called Raklia, and

bears traces of a Greek township with temples to Tyche and Zeus Lophites. See Baumeister in *Philologus*, vol. ix.

HERACLEON, a Gnostic who flourished about 125 A.D., probably in the south of Italy or in Sicily, is generally classed by the early heresiologists with the Valentinian school of heresy. In his system he appears to have regarded the divine nature as a vast abyss in whose *pleroma* were æons of different orders and degrees,—emanations from the source of being. Midway between the supreme God and the material world was Demiurgus, who created the latter, and under whose jurisdiction the lower, animal soul of man proceeded after death, while his higher, celestial soul returned to the *pleroma* whence at first it issued. Heraclæon seems to have received the ordinary Christian Scriptures; and Origen has preserved fragments of a commentary by him on St John's gospel, while Clement of Alexandria quotes from him what appears to be a passage from a commentary on St Luke's gospel. These writings are remarkable for their intensely mystical and allegorical interpretations of the text. The portions of the commentary on St John's gospel have been brought together by Grabe in the second volume of his *Spicilegium*.

HERACLES. See HERCULES.

HERACLIDES, surnamed PONTICUS, a Greek miscellaneous writer who flourished in the 4th century B.C., was born at Heraclæa in Pontus. Removing to Athens, he is said to have been a disciple successively of Speusippus, Plato, and Aristotle. According to Suidas, the second of these philosophers, on departing for Sicily, left his scholars in the charge of Heraclides. The latter part of his life was spent at Heraclæa. Of his private history we have few authentic details. He is said to have been vain and fat, and to have maintained such state in Athens that the wits changed his surname into Pompicus, or the Showy. Various idle stories are related about him. On one occasion, for instance, Heraclæa was afflicted with famine, and the Pythoness at Delphi, bribed by Heraclides, assured his inquiring townsmen that the dearth would be stayed if they granted a golden crown to that philosopher. This was done; but just as Heraclides was receiving his honour in a crowded assembly, he was seized with apoplexy, while the dishonest priestess perished at the same moment from the bite of a serpent. On his death-bed he is said to have requested a friend to hide his body as soon as life was extinct, and, by putting a serpent in its place, induce his townsmen to suppose that he had been carried up to heaven. The trick was discovered, and Heraclides received only ridicule instead of divine honours.

He wrote on a great variety of subjects, but only one fragment, *On Statecraft*, is now extant. This was published with the *Varia Historia* of Elian at Rome in 1545; but the best editions are those of Köller (Halle, 1804), Coray (Paris, 1805), and Müller. See Fr. W. Schmidt, *De Heraclidæ Pontici et Diacarchi Messeni dialogis deperditis*, Breslau, 1867.

HERACLITUS of Ephesus, one of the most subtle and profound of the metaphysicians of ancient Greece, has only of late years had his true position assigned to him in the history of philosophy. To this the obscure and epigrammatic character of his style and the fragmentary condition of his works have in the main contributed, together with the fact that not only his immediate disciples but also his critics, including even Plato, have systematically laid stress upon those features of his doctrines which are least indicative of his real point of view. The true position of Heraclitus is that of the founder of an independent metaphysical system, which sought to get rid of the difficulty, so prominent in the Eleatic philosophy, of overcoming the contradiction between the one and the phenomenal many, by enunciating, as the principle of the universe, "Becoming," implying as it does, that everything is and at the same time, and in the same relation, is not.!

The descendant of a family of leading importance in Ephesus, Heraclitus was born about 535 B.C. His cast of mind was so intensely aristocratic that, filled with contempt for the councils and capacities of his fellow-citizens, he made over the hereditary office of βασιλεύς, which had fallen to him in right of his birth, in favour of his younger brother, and betook himself to a life of solitary meditation. The date of his death was probably about 475 B.C.

To appreciate the significance of the doctrines of Heraclitus, it must be borne in mind that to Greek philosophy the sharp distinction between subject and object which pervades modern thought was foreign, a consideration which suggests the conclusion that, while it is a great mistake to reckon Heraclitus with the materialistic cosmologists of the Ionic schools, it is, on the other hand, going too far to treat his theory, with Hegel and Lassalle, as one of pure Panlogism. Accordingly, when he denies the reality of Being, and declares Becoming, or eternal flux and change, to be the sole actuality, Heraclitus must be understood to enunciate not only the unreality of the abstract notion of being, except as the correlative of that of not-being, but also the physical doctrine that all phenomena are in a state of continuous transition from non-existence to existence, and *vice versa*, without either distinguishing these propositions or qualifying them by any reference to the relation of thought to experience. "Every thing is and is not;" all things are, and nothing remains. With Heraclitus the principle of continuity is opposed to the principle of discretion taught by the Eleatics, and consequently for him "Being and Nothing," as well as "Union and Separation," are logically and physically incapable of distinction. This being so, he naturally enough selects Fire, according to him the most complete embodiment of the process of Becoming, as the principle of empirical existence, out of which all things, including even the soul, grow by way of a *quasi* condensation, and into which all things must in course of time be again resolved. But this primordial fire is in itself that divine rational process, the harmony of which constitutes the law of the universe. Real knowledge consists in comprehending this all-pervading harmony as embodied in the manifold of perception, and the senses are "bad witnesses," because they apprehend phenomena, not as its manifestation, but as "stiff and dead." In like manner real virtue consists in the subordination of the individual to the laws of this harmony as the universal reason wherein alone true freedom is to be found. "The law of things is a law of Reason Universal, but most men live as though they had a wisdom of their own." Ethics here stands to sociology in a close relation, similar, in many respects, to that which we find in Hegel and in Comte. For Heraclitus the soul approaches most nearly to perfection when it is most akin to the fiery vapour out of which it was originally created, and as this is most so in death, "while we live our souls are dead in us, but when we die our souls are restored to life." The doctrine of immortality comes prominently forward in his ethics, but whether this must not be reckoned with the figurative accommodation to the popular theology of Greece which pervades his ethical teaching, is very doubtful.

The only extant work, purporting to have been written by Heraclitus, which can be regarded as genuine, is the treatise *Περὶ φύσεως*, which has come down in a fragmentary condition. It has been edited by Bywater (*Heracliti Ephesii Reliquiæ*, Clarendon Press, 1877). The Epistles are in all probability spurious.

The school of disciples founded by Heraclitus flourished for long after his death, the chief exponent of his teaching being Cratylus. A good deal of the information in regard to his doctrines has been gathered from the later Greek philosophy, which was deeply influenced by it.

By far the most complete exposition of his system is that of Lassalle (*Die Philosophie Herakleitos des Dunkeln von Ephesos*, Berlin, 1858), although his interpretation is decidedly too strongly dominated by modern Hegelian conceptions. See also Hegel, *Gesch. d. Phil.*; Zeller, *Gesch. d. Phil. d. Griechen*; Bernays, *Die Heraklitschen Briefe*, Berlin, 1869; and Schuster, *Heraclitii von Ephesus*, Leipzig, 1873.

HERACLIVS (c. 575-641), emperor of the East, was born in Cappadocia about 575. He was brought into notice by his heading a successful revolt against the emperor Phocas in 610, when he usurped the usurper's throne. At that period the eastern provinces of the empire were being ravaged by the triumphant armies of Chosroes (Khosroes) II., which in the first twelve years of Heraclius's reign continued their unresisted progress to the Bosphorus and the Nile, pillaging Asia Minor and Syria, and reducing Constantinople to the utmost distress by cutting off its Egyptian corn supplies. In 618 the public distributions of grain, which had been carried on since Constantine had instituted them as a bribe to attract citizens to his new city in 330, were suspended; and the bankrupt emperor was hardly dissuaded

by the almost imperative prayers of his people from quitting his capital in shame and fear for Carthage. Taking courage, Heraclius appears to have set himself to the task of reorganizing both state and army, a labour which had probably occupied him since his accession. He was menaced on the west by the fierce tribe of the Avars, who were casting longing eyes on the riches of the imperial city; but in 620 he succeeded in making a treaty with them, and interposed a human barrier against their further encroachments by inviting the Serbs and Croats to settle in the intervening regions, which they have never since left. In 621 Heraclius led an army into camp in Asia Minor, and devoted himself with ardour to the drilling of his inexperienced troops. Every military manœuvre, every useful exercise and even hardship, was ordered and shared by the emperor. He kindled the enthusiasm of his soldiers by his stirring words, and excited their admiration and affection by his deeds. Next year he led his forces against Persia, and within five years, in a series of brilliant campaigns that place him side by side with the greatest generals of the world, he overthrew the pride of that empire, drove its monarch a fugitive from his throne, and enriched his exulting troops with untold wealth. Siroes, the son of Chosroes, revolting against his unhappy father, put him to death in 628, and speedily made a peace with Heraclius, according to which the Persian empire retired to its former limits, prisoners were mutually given up, and the true cross, carried from Jerusalem by the Persians, was restored to Christian hands. Heraclius returned in triumph to Constantinople, which had in his absence two years before successfully repulsed a combined assault by the Avars and Persians; and in 629 he proceeded to Jerusalem to restore solemnly the holy relic to its ancient place. But he was not long to enjoy the peaceful fruits of victory. A mighty power had been steadily growing up in the hot sands of Arabia, and was now coming to measure its strength with that of the Roman empire. In 632 the Mahometans invaded Syria; and, overthrowing the armies sent to oppose them, in six years they made themselves masters of the country. Egypt next fell before Islam, and in 640 that fair province of the empire was Mahometan. The people of Asia Minor alone successfully resisted the advancing Saracens. Heraclius seems meanwhile to have sunk into a sort of lethargy, as though his efforts in Persia had completely exhausted him. While his generals and armies were being cut to pieces he was engaged at Constantinople, whither he had retreated in 634, with speculative theological questions. In 638 his *Ecthesis* appeared, which, tinged with the heresy of Monothelism, was probably drawn up by the patriarch Sergius. The energy of his earlier life never returned, and in 641 he sank under a long-continued disease. He had been twice married; the second time to his niece Martina, an illicit union which he compelled the reluctant Sergius to celebrate. His eldest son, Heraclius, succeeded him, taking the title of Constantine III.

The character of Heraclius is a curious riddle, which it is not easy to solve. Personally brave, and possessed of tried ability as a diplomatist and a general, in his latter years he passively allowed his empire to fall to pieces before his eyes,—presenting in the periods of his life a contrast that would almost seem to argue the possession of not merely contrary but contradictory qualities. But we must not forget that our information regarding the inner details of his latter reign is very imperfect, and that possibly there may be some reason, though hardly an excuse, for his conduct. It would have been better for his fame if he had died immediately after his Persian campaigns.

See Gibbon's *Decline and Fall of the Roman Empire*; Le Beau's *Histoire du Bas-Empire*; and the works of George of Pisidia (*cf.* vol. x. p. 429).

HERALDRY

HERALDRY, though etymologically denoting all the business of the herald, has long in practice been restricted to one part of it only, and may be defined as the art of blazoning or describing in proper terms armorial bearings. It treats also of their history, of the rules observed in their employment and transmission, of the manner in which by their means families and certain dignities are represented, and of their connexion with genealogies and titular rank.

Particular symbols have in all ages been assumed by the various families of mankind, civilized and uncivilized. Such were the lion of the tribe of Judah, the S. P. Q. R. upon the standards of ancient Rome and the eagle surmounting them, the tattoo marks of the savages of America and the Pacific, the Danish raven, and the white horse of Saxony, which still remains carved upon the chalk downs of western England.¹ Heraldry, however, is a purely feudal institution, coeval with close armour, devised possibly in Germany, adopted and improved in France, Spain, and Italy, and imported into England by the Norman invaders and settlers. Its figures have little or nothing to do with the older symbols, though these have occasionally been incorporated into its charges, and an apparent connexion thus established between them. These symbols, as has been well said, were the precursors and not the ancestors of heraldic bearings. The supposed connexion, however, misled the credulous heraldic writers of the 16th and 17th centuries, and caused them to attribute coats of arms to the heroes of sacred and profane history, who were certainly as ignorant of heraldry as ever was Adam of Genoa.

"Arms" or "armories," so called because originally displayed upon defensive armour, and "coats of arms" because formerly embroidered upon the surcoat or camise worn over the armour, are supposed to have been first used at the great German tournaments, and to have reached England, though to a very moderate extent, in the time of Henry II. and Cœur de Lion. To "blazon," now meaning to describe a coat of arms, is the German "blasen," to blow as with the horn, because the style and arms of each knight were so proclaimed on public occasions. The terms employed in heraldry are, however, mostly French or of French origin. Though now matters of form and ceremonial, and subject to the smile which attaches to such in a utilitarian age, armorial bearings were once of real use and importance, and so continued as long as knights were cased in plate, and their features thus concealed. At that time leaders were recognized in the field by their insignia alone, and these—both figures and colours—became identified with their fame, from personal became hereditary, were subject to certain rules of descent, and to the laws of property and the less certain rules of honour.

Froissart mentions a case in which a knight of the Scrope family could with difficulty be restrained from putting to death a prisoner because he wore the same bearings with himself. The last Do Clare owed his death on the field of Bannockburn to his having neglected to wear his cotte d'armes; had he been recognized, his great value as a prisoner would have saved him. Also the loss of the battle of Barnet was in part attributed to the similarity between the royal cognizance of a sun and that of John

de Vere, a star with streamers,—Warwick charging Oxford by mistake for the king.

The best if not the only absolutely safe evidence for the origin of armorial bearings is that afforded by seals. Seals were in common use both before and after the introduction of armorial bearings, and they are not so likely as rolls of arms or monumental effigies to be the work of a later age. There are said by Courcelles to be extant, appended to charters of 1030 and 1037 A.D., two seals of Adalbert, duko of Lorraine, which bear on a shield an eagle with wings closed. This however wants confirmation; but Anna Comnena, describing the shields of the French knights who visited Constantinople about 1100, gives their surfaces as of metal only, polished but plain; nor have any decided traces of arms been discovered among the early crusaders. Louis le Jeune, who seems first of the French kings to have used the fleur-de-lys, caused it to be represented in gold over the azure mantle and chausses worn by his son at his coronation. Also, in 1180, he seals with a fleur-de-lys, but it is placed in a circle, not upon a shield. Planché cites two seals of Phillip, count of Flanders, one plain, in 1157, and another in 1164 charged with a lion, their subsequent bearing. Seton mentions the seal of John de Mundegumbri in 1170 as bearing a fleur-de-lys, which, like that of Louis, has two intermediate flower-stems, as seen on Florentine coins. He also gives the seal of Falconer (1170) as bearing a falcon; and that of Corbet bore two ravens perched upon a fleur-de-lys, while his brother bore them upon a tree. This indeed was at a period when fleurs-de-lys, stars, and various animals were commonly represented as mere ornaments on seals, but the peculiarity of the instances named is that the falcon and the raven, like the fleur-de-lys of France, were afterwards the heraldic bearings of those families. The seals of the close of the 12th century, though not generally heraldic, certainly betray many of the elements of heraldry. No doubt, when once introduced, armorial bearings were felt to supply a real and serious want, and came rapidly into use, but Wace, the poet of the reign of Henry II., although he tells us that

"N'i a riche home ne Baron,
Ki n'ait lez li son gonfanon,
U gonfanon a autre enseigne,"

can scarcely be seriously held to mention armorial bearings.

It is uncertain at what period armorial bearings found their way into England. The Conqueror and his successors certainly did not use them; they do not appear upon their seals, nor are they shown upon the banners of the Bayeux tapestry. The monk of Marmoutier, probably a contemporary, describes Henry I., upon the marriage of his daughter to Geoffrey of Anjou in 1122, as hanging about the bridegroom's neck a shield adorned with small golden lions, "leoculos aureos;" and, making mention of a combat in which Geoffrey was engaged, he describes him as "pictos leones preferens in clypeo." It is true that the number, attitude, and position of these lions on the shield are not specified, but considering that not long afterwards two lions became the arms of Plantagenet, and so of England, this may fairly be taken as their introduction. Stephen is said to have used a centaur, Sagittarius, as an emblem, because he landed in England when the sun was in that sign, but on his great seal his shield is quite plain, save a ridge down the centre, evidently a part of its construction. On the seals of the Conqueror, Rufus, and Henry I., only the hollow or under side of the shield is shown; so there probably was no design upon the front. There is no seal of Duke Robert, but William, earl of Flanders, his son, shows

¹ The subject of ancient and especially of Greek "heraldry" is discussed by Curtius in a learned and interesting paper "Wappengebrauch und Wappenstyl im Alterthum" in the *Abhandlungen der Königl. Akad. d. Wissenschaften zu Berlin* (1874). See also article *Gems*, vol. x. p. 136.

plain shield on his seal. His monumental effigy (1128) bears a large pavese shield, and upon it an escarbuncle, apparently a highly ornamented clasp. The seal of Henry II. also shows the hollow of the shield: The first great seal of Richard I. bears a lion rampant, who from his position may be inferred to be fighting with a similar lion upon the sinister and concealed half of the shield, blazoned in a MS. cited by Mr Way as "two lions confrontés."

Up to this time the kings, though represented on horseback and in full armour, have the face uncovered, and therefore their persons would be known. The seal of Richard I. in 1189 shows a close helmet, and upon the shield two lions passant gardant in pale, "leones lopardés," as they were then or soon after called. On a later seal, after his return from captivity in 1194, Richard added a third lion. John, while earl of Mortaine, sealed with two lions, but his seal as king bears three, and the coat has so remained. That the two lions were more than a mere ornament is evident from their having been adopted by John's natural son, Richard de Warren, who seals with two lions passant regardant. The seals of the great barons show the growth of the practice. Richard, constable of Chester, contemporary with Stephen, bears a shield covered over with small plates, tegulated, like his armour; but Stephen, earl of Richmond, as early as 1137, seals with seven fleurs-de-lys, a very early heraldic seal. Waleran, earl of Meulan (died 1166), also used an heraldic seal. Duchesne gives a seal of Bouchard de Montmorenci (1182), a contemporary of Louis le Jeune, with a cross between four alerions on his shield, and another in which the cross is charged with roundels. Mathieu, his son, seals also with the cross and alerions, which had evidently become, as they remained, hereditary. In England, William, earl of Essex (died 1190), seals with the escarbuncle of his family. In 1187 Gervase Paganel, a great Anglo-Norman baron, seals with two lions passant, which his family continued to bear.

With the 13th century arms came rapidly into use. The second seal of Mathieu de Montmorenci in 1209 has them introduced upon his horse furniture, but this practice does not appear upon the seals of the kings of England until the second seal of Edward I. Baldwin de Bethune, earl of Albemarle (died 1214), sealed with three martlets in chief, and many other early examples of regular heraldic seals occur at this period attached to extant charters. The earliest roll of arms is of the reign of Henry III.; of a second of the same reign a copy is preserved in the Harleian collection; and a third, in the next reign, is the roll of Caerlavrock, 1300 A.D. So that for the reign of Henry and his son the evidence for armorial bearings is copious and excellent. Other rolls exist carrying the practice through the 14th and 15th centuries, before the middle of which there is no known work on heraldry, nor any trace of heraldic regulations save what may be deduced from recorded practice.

Coats of arms were not at first strictly hereditary, nor even always permanent in the same person. Thus William de Ferrars, 6th earl of Derby (died 1246), seems to have borne "argent, 6 fers de cheval, or horse shoes, 3, 2, 1, sable." William, his son, in consequence of a match with Peveril, who bore "vair," changed his bearing to "vair, or and gules, on a border azure 8 horse shoes argent." Robert his son, 8th earl (died 1278), dropped the horse shoes, and bore "vair, or and gules."

"Ferrars his tabard with rich vair yspread."

After the match with Quincy, the Ferrarses laid aside their own coat and bore that of Quincy, "gules, 7 mascles conjoined 3, 3, 1, or." Their male heir through a younger branch,—Ferrars of Baddesley-Clinton,—commemorates these various changes by bearing "quarterly,—(1st) vair, or and gules; (2d) sable, 6 horse shoes, 3, 2, 1, argent; (3d)

gules, 7 mascles, 3, 3, 1, or, a canton ermine." Hugh Lupus, earl of Chester (died 1101), is fabled to have borne a wolf's head, and not improbably his surname arose from some such emblem. Richard, his son, is said to have borne "azure, semée of crosslets or, a wolf's head erased argent." Ranulph Meschines, 3d earl (died 1128), was sister's son to the first earl, and to him is assigned "or, a lion rampant gules." Hugh Cyfelioc, 5th earl (died 1180), certainly bore "azure 6 garbs of wheat, 3, 2, 1, or;" and Ranulph Blondville, his son, bore "azure, 3 garbs or." With him the line failed, but as the wheat-sheaf is a common Cheshire bearing, it is probable that arms came into general use in the palatinate in the time of the last two earls.

Sir Nicholas Carru (died 1283) seals with a tricoöporate lion, but at Caerlavrock in 1300 is found with a

"Banière et janne bien passable,
O trois passans lycens de sable,"

the arms of the Carews of our day. The fess and label of Saher de Quincy, earl of Winchester, in 1170, were changed by Roger his son for the mascles by which they were best known, and which he repeats upon his housings. The fact is that, at the close of the 13th century, arms, though on the whole hereditary, had not quite acquired that fixed character that belonged to them half a century later. That the changes were the exception rather than the rule is, however, clear from the roll of Henry III., and from the arms of the forty great barons which he caused to be painted on the walls of Westminster Abbey, almost all of which, so far as they are on record, are the same with those borne or quartered by their representatives. There exist also in England a few families of Norman origin, the period of whose arrival in England is known, and whose arms are the same with those of the present stock in the parent country. Such are Harcourt of Ankerwyke and D'Aubigny, who therefore bore their arms before the separation from Normandy under Henry III.

Early bearings were usually very simple, the colours in strong contrast, and their form and outline such as could readily be distinguished even in the dust and confusion of a battle. They are mostly composed of right lined figures known in heraldry as ordinaries. The favourite beast is the lion.

The earliest and most valuable records relating to English armorial bearings are undoubtedly the rolls of arms of the reigns of Henry III. and the first three Edwards, which have been well edited by Sir H. Nicolas. That of Henry III. known as Glover's roll, drawn up between 1243 and 1246, describes or blazons 218 coats of arms, and therefore shows very sufficiently the heraldry of the period. Of these coats nearly one-half are composed solely of the ordinaries and subordinaries, and other simple lines and figures. About two score of them exhibit lions, chiefly rampant, and leo-pardés, a form of the same animal. The only other beast is the "teste de sanglier" borne by Swinburne. Of birds there are but the eagle and the papagay, several martlets, and single examples of the raven, the cock, the heron, and the horiöle. The lnce or pike is the only fish. The cinquefoil and sexfoil, the fleur-de-lys, the rose, and the wheat-sheaf, used very sparingly, represent the vegetable world. For the rest there are annulets, barnacles, crescents, estoiles, escallops, fers de cheval, mullets, and water budgets. There is one ray of the sun, and one whirlpool.

The coat of Mortimer "barré, a chef palée, a corner gerennée d'or et d'azur, a ung escancheon d'argent,"—or, in modern terms, "barry, a chief paly, its corners gyronny or and azure, an escancheon argent" (fig. 63),—is the only one at all of a complex character, and this is composed of ordinaries and subordinaries; and though many of the ordinaries bear the smaller charges, or are placed between them, there are very few examples of an ordinary so charged also

placed between charges, a common usage in later coats. An exception is Chandos, who bears three estoiles on a pile, which again is placed between six others; but this stands alone.

The roll of Edward II. blazons 957 coats of the bannerets of England, so that the use of arms had increased considerably. The lions have risen to 225, the eagles to 43; and there are 102 crosses of various kinds. Of new beasts, fabulous or real, there are the griffin, the wyvern, the stag, wolf, goat, and greyhound; of new birds, the falcon; of fishes, the dolphin. Of other objects the additions are the millrind, buckle, covered cup, chaplet, gauntlet, arrow, trumpet, hammer, battle-axe, palmer's staff, pots, winnowing fans or vans, pens, cushions, and chessrooks. The character of the arms remains very simple, and the blazon employed agrees in the main with that still in use, and is in general perfectly intelligible. These rolls give various examples of changes of coats, either altogether or by the introduction of a difference to distinguish members of the same family; and it is observable that when the figures are altered the colours are usually adhered to, as though it were considered undesirable to change them. Thus Gilbert de Segrave (died 1254) bore "sable, 3 garbs argent." Of his grandsons John and Nicholas, John bore the paternal coat, but Nicholas, at Caerlaverock, had exchanged the garbs for a lion. This afterwards became the family bearing as "sable, a lion rampant argent, crowned or," the colours being retained.

No sooner had the great barons assumed arms for themselves than they began to grant them to their followers. Arms so granted commonly bore some resemblance to those of the grantor, and hence certain charges prevailed in certain districts. Thus the chevron of De Clare was common in South Wales, in the Honours of Gloucester and Clare, and about Tonbridge. The garb or wheat-sheaf was found in Cheshire; the cinquefoils of the Bellomonts in Leicestershire; the annulets of Vipont in Westmoreland; the lion all over England, and the tressure in Scotland, both from the royal arms. Some of these grants remain; others can with certainty be inferred. Stephen Curzon, who held under the earls of Derby, bore "vair, with a border of 8 popinjays argent," and Richard, his brother, bore "vair, on a fess 3 horse-shoes." Hubert, earl of Kent, bore "7 lozenges vair;" and Anselm de Guise, on taking under him lands in Berks and Gloucester, assumed the same coat, with the addition of a canton or, charged with a mullet sable. In 1349 Robert Morle granted to Robert de Corby and his heirs the arms "d'argent, ove un saltier engrailé de sable," which he himself had inherited from Baldwin de Manoirs. In 1356-7 William, baron of Greystock, who bore "barry of 6 argent and azure, 3 chaplets gules," granted to Adam de Blencowe and his heirs for ever "an escutcheon sable with a bend clostted [or barred] argent and azure, with 3 chaplets gules." In 1391-2 Thomas Grendale granted to William Morgue his heirs and assigns, "argent, on a cross azure 5 garbs or," which, as cousin and heir, he himself had inherited from John Beaumeys. Finally, in 1442, Humphrey, earl of Stafford, who bore "or, a chevron gules," granted to Robert Whitgreaves "un escue d'azure, à quatre points d'or, quatre chevrons de gules," to him and his heirs of lineage,—in modern terms "azure, a cross quarter-pierced or, on each limb a chevron gules." A coat of arms was not only heritable, subject to certain heraldic customs, but could be willed or granted away, wholly or in part, like chattel property.

The crusades, by bringing together soldiers of different nations, tended to produce a certain assimilation in their heraldries, but their influence upon the arms themselves has been exaggerated. The stories as to bearings adopted to commemorate feats of arms in Palestine are mostly

inventions. The cross no doubt was a crusading bearing, but it was so because it was the emblem of Christianity, and primarily popular as such. The stars, torteaux, water budgets, and other charges attributed to the crusaders, were of earlier date and of independent origin. There is no evidence that the crosses patée of the Berkeleys, or the crosslets of Beauchamp, Clinton, Windsor, and Howard, were added to their simpler bearings in token of services in the Holy Land. The star of De Vere, always attributed to an adventure there, was evidently a mark of cadency, adopted by Robert de Vere, brother of Alberic, 2d earl of Oxford. The fact appears to be that most of the additions to or alterations in the earlier coats of arms were made for some genealogical reason, to commemorate a match with some great family or to distinguish between the several branches from the parent tree. After, usually long after, the period of the crusades, arms were invented for "fabled knights in battles feigned," and but few of the Saracens' heads which figure so prominently in many coats of arms are contemporary with any Saracenic war.

The diversion of the tournament did even more than actual war to promote the glories of heraldry. On these occasions the presence of spectators, and especially of ladies, encouraged all sorts of heraldic display. At a tournament at Calais in 1381 Richard Beauchamp, earl of Warwick, one of the most accomplished knights of the reigns of Richard II., Henry IV., and Henry V., suspended on three shields three several coats of arms, as representing three several knights who professed to be ready successively to meet all comers. Three French knights appeared to the challenge. Against the first the earl came forth as the green knight with a black quarter, bearing "silver, a maunch gules," the arms of De Tony, a maternal ancestor, and so overcame his adversary and retired unknown to his pavilion. On the second day he appeared as the green knight, and bearing "silver, two bars, gules," the arms of Mauduit of Hanslope, another ancestor, he met a second knight with equal success. On the third day he appeared in his proper person bearing the arms of Guy of Warwick and Beauchamp on his shield, and those of De Tony and Mauduit on his caparisons, and thus with great honour won the third day also.

The shield, as the most obvious piece of the defensive armour, was that upon which arms were first displayed. The Norman shield was of wood covered with hide, and clamped and stiffened in a fashion which is thought to have given rise to the first simple bearings. It was 3 to 4 feet long, pointed below, and 18 inches broad. This shield is common on early monumental effigies armed in chain mail, and it is unusual to find it with armorial bearings. It was succeeded by the small triangular heater shield, and that, in the reign of Edward III., by a somewhat larger and full bottomed shield, which by degrees ceased to be used in war, and became more and more an architectural ornament. The arms were also displayed upon the breast-plate, and upon the camise or surcoat that covered the armour, and were repeated upon the housings of horses both before and behind the saddle. When the Comte d'Artois fell at Damietta, the Saracens showed in triumph his "cotte d'armes toute dorée et fleur-de-liséé." The emperor Henry of Luxembourg is described in the *Chronicle of Flanders* as bearing "an aigle noir, sur un tornielo d'or qui pendoit jusq' a mi-jambe." Sir Alexander Nevile appeared at Halidon Hill in a surcoat of his own arms, the quarters filled up with the arms of his friends. The fine effigy of William de Valence at Westminster is decorated with small escutcheons of his arms on various parts of his dress and weapons. An actual remnant of the richly embroidered surcoat of William de Fortibus, earl of Albermarle (died 1261), is still preserved, and has been engraved in the

Archæologia. It was against the embroidery of the surcoat that the severe sumptuary enactments of Richard and Philip Augustus were mainly directed.

The importance attached to armorial bearings is strongly shown in the uses to which they were applied. A sovereign who wished to assert his claim to a kingdom placed its arms upon his shield. In 1479 when Alphonse of Portugal resigned his claim to Castile, he was required to lay aside its armorial ensigns. It appears that when Edward III. assumed the French lilies, he at first did so simply as representing his mother, who was an heiress, and placed her arms in his second quarter; when, however, he claimed the kingdom of France in her right, he removed the lilies to the first quarter as representing the more important kingdom. A grant of arms at the hand of a sovereign had great value. Among the more solid bribes which Louis XI. bestowed upon the courtiers of Edward IV. occurs a grant of three fleurs-de-lys to a knight of the Croker family. Thus also when Juan de Orbieta captured Francis I. on the Ticino, he was rewarded by a grant of arms from Charles V., though of so complex a character as to do little credit to Spanish heraldry. In later times John Gibbon, the heraldic author, having a quarrel with two maiden ladies of his name, obtained a licence to convert the scallops in their common coat into the black balls called ogresses,—a most heraldic revenge.

Armorial bearings were largely painted, enamelled, and embroidered upon personal ornaments, furniture, and weapons. The sword of Edward, prince of Wales (died 1483), is a curious example of this; it bears on its pommel the words "aves fortes" and five shields:—(1) England, (2) the duchy of Cornwall, (3) England and France with a label, (4) Mortimer quartering Ulster, (5) the earldom of Chester. In the middle is the cross of St George. The citizens of London were bound to provide their banner bearer, Lord Fitz Walter, with "a saddle with his arms," and the seal of one of that family, about 1300, shows the arms upon the back or rest of his war saddle. The seal of Sir Hugh le Despenser (1292) also so shows his arms. Various bequests of plate and furniture with arms occur in the 14th century. In 1368 William, Lord Ferrars of Groby, bequeathed his green bed "with his arms thereon, and his furniture bearing the arms of Ferrars and Ufford, impaled." In 1380 Edward Mortimer devised "à notre tres chier friere John Gilbert, evesque de Hereford, une plate de argent pour espices et enamillés ove les armes de Mortimer en la face."

Richard, earl of Arundel, in 1392, bequeathed a canopy of the arms of Arundel and Warren quarterly. In 1399 Eleanor Bohun, duchess of Gloucester, had a psalter with her father's arms upon the clasps. In the Decorated and Perpendicular styles of architecture shields of arms are common ornaments. Those of benefactors were set up in church windows in glass, and those of a family in their houses. In the Scrope roll is a list of sixty-six churches in which the Scrope arms were set up, and the histories of Dugdale and Burton show us that nearly every church in Warwickshire and Leicestershire had a multitude of arms on its windows. Those still remaining in the east windows of Bristol cathedral are early and good examples of the arms of great barons, Berkeley, Clare, and Warren. They are also seen upon floor tiles of the same period.

As arms became hereditary, and their use ceased to be confined to the battle-field, but was largely extended to seals and ornaments, it was natural that some notice should be taken of the arms of females, and that the wife's coat should be combined in some way with that of the husband, especially when she was the last of, and represented, her family. This seems first to have been managed by giving the wife a separate shield. The kings of France so bore

the arms of Navarre after the marriage with the heiress of that kingdom. Another very early plan was to form a composite coat. Thus the old coat of Willoughby was fretty, but on their marriage with Bec of Eresby, they adopted the coat of Bec, and Sir John Willoughby (13th Edward III.) bears the cross moline of Bec, but the wings of his crest are fretty for Willoughby, and on either side is a buckle taken from the arms of Roscelin, his wife. Rose of Kilraveck bore "or, 3 water budgets sable," but on a marriage with the heiress of Chisholm they added "a boar's head coupé gules" from her arms. So also Halyburton of Pitcur, who bore "or, on a bend azure 3 lozenges of the field," after a marriage with another Chisholm heiress, added to their coat "3 boars' heads erased sable." Bohun, who bore "azure, a bend argent, cotised or, between 6 lions rampant of the third," is thought to have added the bend on the occasion of a marriage with Maud, daughter and heir of Milo, earl of Hereford. As this, however, led to complexity and indistinctness in the bearings, and the introduction of a second shield was obviously inconvenient, the method of impalement was devised, by which the sinister half of the shield was appropriated to the lady's arms, at first under the process known as dimidiation. When, however, the lady was an heiress, a different plan was adopted which ultimately led to quartering or the marshalling of many coats in one shield, a practice, when pushed to any extent, quite inconsistent with the original use of coat armour. This also led to a corresponding alteration in the shape of the shield, which was expanded to contain the arms of each heiress who had married into the family, together with such other heiresses as her family had previously been allied with, so that when a Percy heiress married a Seymour, she added her heiress ancestors' arms with her own arms to those of her husband, expanded in a similar fashion by the previous matches of his family. Thus the great shield of a family became a compendium of the family pedigree which, to those who could read its language, conveyed a considerable mass of semi-historical information. The defect of this system was that it only took account of heiresses, and did not provide for the purity of the whole descent, so that under it the children of a man of no birth, who married a great heiress, would display all her quarterings, and no account would be taken of the absence of any on his side; and further, if it happened, as was actually the case in the last century with the Rodneys of Rodney-stoke, that a family, though ancient, had never intermarried with an heiress, they could display no quarterings.

In France and Germany and to some extent in Scotland a far more perfect system was pursued. There the genealogical escutcheon included the arms of every ancestor and ancestress, whether an heiress or not; thus one generation gave two coats, two generations four coats, and so on. "Seize quartiers" gave evidence of pure blood for four generations, and thirty-two quarters, the qualification for a canon of Strasburg, for five.

As the combinations out of which the early coats were formed were limited, it occasionally happened that two persons of the same nation bore the same arms, and this gave rise to disputes which, as matters connected with military discipline, came under the jurisdiction of the earl marshal. One of the earliest of these disputes is mentioned in the roll of Caerlaverock—

"Le beau Bryan de Fitz Aleyn,
De courtesie, et de honneur pleyn,
Ivi o baniere barrée,
De or et la gouls bien parée,
Dont le chalenge estoit le pointz,
Par entre lui et Hue Poyntz,
Ki portoit cel ni plus ni moins,
Dont merveille avoit meinte et melns."

Cases of a similar character were decided between

Harding and St Loo in 1312, Warburton and Gorges in 1321, and Sytsylt and Fakenham in 1333, when Sir William Fakenham disputed the arms, "le champ de disce barretz argent et azure, supportez de cinq escocheons sables, chargés ovesque tant de lyons primers rampant incensés gules." They were adjudged by a commission to Sytsylt. Hugh Maltby and Hamon Beckwith had a similar dispute in 1339. But by far the most celebrated dispute of this nature arose in 1384 between Sir Richard Scrope of Bolton and Sir Robert Grosvenor, for the right to bear the arms "azure, a bend or." The greatest men in the country, including John of Gaunt, gave testimony on one side or the other, and it was shown that each family had used the coat beyond the memory of man. It was finally adjudged to Scrope, and Grosvenor was directed to bear "les ditz armes ovo une pleyne border d'argent." Grosvenor, however, declined to accept the arms so differenced, and assumed "azure, a garb or," retaining his colours and marking his connexion with the old earls of Chester. It was proved, incidentally, that an ancestor of Grosvenor's had granted his coat, with a difference, to William Coton of Coton. It is remarkable that both disputants are still represented in the male line, and continue the arms as then settled. Both families had previously had disputes with other parties, and the Scopes long afterwards had a quarrel with the Stanleys for the right to bear the arms of the Isle of Man. The matter was compromised by Edward IV. The Hastings and Grey de Ruthyn case, which rises to the rank of a tragedy, illustrates still more forcibly the value attached to a coat of arms. On the death, childless, in 1389, of John de Hastings, earl of Pembroke, a dispute arose for his heirship between Reginald Grey, his heir-general, and Edward Hastings, the heir male and of the name, but of the half-blood. A court military decided in favour of Grey. Pending the trial Hastings had ceased to difference his arms as a cadet, and assumed them unbroken. He was, however, ordered to bear them with a label, and for contumacy was imprisoned for sixteen years. A suit for arms was decided as lately as 1720 in Blount *versus* Blount, in the earl marshal's court.

The same necessity that made it important to prevent the use of similar bearings by different families in the same country made it also necessary to distinguish between the bearings of different members of the same family, all of whom had a right to the paternal coat. As this right was strongest in the eldest son he alone bore the paternal arms unaltered (in French heraldry "sans brisure"); and the other sons were obliged to introduce some sufficient change, called in heraldry a "difference." This was at first managed by inverting the colours or substituting one ordinary or one inferior charge for another, as a bend for a fess, martlets for mullets, and the like; and sometimes by the use of a coat compounded of the paternal bearing with that of an heiress. A multitude of these early differences occur in the rolls of Henry III. and Edward II., and in various early lists of arms. The family of Grey, always numerous, differenced their cadets in at least fourteen different ways, almost all preserving in some tangible form the paternal coat; and this was also the case with the very numerous family of Basset. Generally no rule is followed, save that on the whole some reference is retained either to the charges upon, or the colours of, the paternal coat. Very frequently, even in the earliest times, the eldest son differenced his father's coat by a label. In the roll of Henry III. the label occurs fifteen times, though not always as a difference. Gradually, however, it came to be used almost entirely for that purpose, and finally a set of marks, called of cadency, were devised for each of the sons, the label being the mark of the eldest during his father's life.

All these rules and alterations were, however, the growth

of a later age, and came into use as the bold and simple heraldry of the 13th and 14th centuries began to be overlaid with florid fancies. So long as heraldry represented a real want, its expressions were simple and intelligible, but as "villainous saltpetre" came into use and closed helmets were laid aside, and as skill and strategy rather than personal valour became the attribute of a leader, armorial bearings fell into disuse in war, and were no longer worn upon the person, or upon the horse trappings. But though armorial bearings ceased to be of actual use, they continued to be emblems of rank and family, and a mark of gentle blood. They became, however, exceedingly and often absurdly complex, partly because simplicity was no longer necessary, and partly because it was scarcely practicable, owing to the enormous increase in the number of the gentry, which produced a demand for new combinations.

The glories of heraldry reached their zenith in the reign of Richard II., with "youth at the prow and pleasure at the helm" of the vessel of the state, but it was not till the reign of Richard III. that it was thought necessary to place under specific control the whole heraldry of the kingdom; and this, in close imitation of the example of France, was done by the incorporation of the heralds into a college placed under the presidency of the earl marshal.

The office of the herald as the messenger of war or peace between sovereigns or between contending armies in the field is of far earlier date than the introduction of armorial bearings, but as these came into use they were gradually placed under his charge, and he took his specific name sometimes from that of the noble or leader who employed him, sometimes from one of his castles or titles of honour, and sometimes from one of his badges or cognizances, which the herald wore embroidered upon his dress and by which he was known. In the pages of Froissart and other chroniclers frequent mention is made of heralds-at-arms and their attendants the pursuivants, and we read of Somerset and York, Windsor, Chester, and Lancaster heralds, Claroncieux, Arundel, Fleur-de-Lys, and Leopard; and of pursuivants, Antelope, Blanch Lion, Falcon, Portcullis, and many more. At an early period the principal heralds, and especially those attached to sovereigns, were called kings-at-arms, and as early as Edward I. an officer, called from his jurisdiction, Norroy, was placed in charge of the heraldries north of the Trent. It is probable that a herald was always attached to each order of chivalry, as Toison d'or to the Fleece, and Garter to the chief English order. Garter, however, was only officially appointed by Henry V., when he seems to have been recognized as the principal king-at-arms—"Principalis rex armorum Anglicanorum." At the institution of the college, or soon afterwards, it was decided that its officers should be Garter, principal king-at-arms; Norroy and Claroncieux, provincial kings north and south of Trent; six heralds, Windsor, Chester, Lancaster, Richmond, Somerset, and York; and four pursuivants, Rouge Croix, Blue Mantle, Rouge Dragon, and Portcullis; who constitute the present establishment, though some special officers have since been appointed, as a king-at-arms to the revived order of the Bath, and some others, not members of the college.

It became the duty of the new incorporation to take note of all existing arms, to allow none without authority, and to collect and combine the rules of blazoning into a system. To effect a supervision of the armorial bearings throughout the kingdom, it was necessary to visit the several counties. Such a commission of visitation seems to have been issued by Henry IV. as early as 1412, but the first regular commission acted upon was issued by Henry VIII., 1528-9, and the last early in the reign of James II. The visitations were taken about every thirty years, and for contemporary events are most valuable records. The provincial king, either

personally or by deputy, visited the capital town of each county in his division, and summoned the surrounding gentry to record their pedigrees, and show a title to their armorial bearings. The earl marshal's court survived the fall of the house of Stuart, and a few causes relative to a right to particular arms were decided in the course of the last century, but its powers fell into disuse, and not long since it was finally abolished, and with it fell any pretence on the part of the college to regulate, by compulsory authority, the heraldry of the kingdom. At present, however, notwithstanding the democratic tendencies of the age, armorial bearings are in greater demand than ever in England, and more or less coveted in the United States, and a good deal of the proper business of heraldry is still transacted within the college of arms, and a good deal more, irregularly and improperly, outside it. A considerable number of persons still bear arms derived from an ancestor who bore them before the institution of the college; others bear them under grants and patents from that body; and others still more numerous, who or whose fathers have risen from obscurity, have assumed arms according to their fancy, or under the uninstructed advice of some silversmith or finder of arms. The Smiths, said a distinguished member of the family, had no arms; they sealed their letters with their thumbs. It is to avoid so inconvenient a signet that the new men have recourse to the demi-lions and demi-griffins now so much in vogue, and possibly because they are not aware that Garter and his colleagues are still willing to grant arms, crest, and motto, on terms within reach of almost every aspirant to chivalry.

There is no college or corporation of heralds in Scotland or Ireland; but in Scotland heraldry has been to the full as much considered, and at least as well regulated as in England. "Lyon-king-at-arms," "Lyon rex armorum," or "Leo fecialis," called from the lion on the royal shield, is the head of the office of arms in Scotland. When first the dignity was constituted is not known, but Lyon was a prominent figure in the coronation of Robert II. in 1371. The office was at first, as in England, attached to the earl marshal, but it has long been conferred by patent under the great seal, and is held direct from the crown. Lyon is also king-at-arms for the national order of the Thistle. He is styled "Lord Lyon," and the office has always been held by men of family, and frequently by a peer. His powers have been declared by statute, and extend to fine and imprisonment. He is supreme in all matters of heraldry in Scotland. Besides the "Lyon depute," there are the Scottish heralds, Islay, Rothesay, Marchmount, Albany, Ross, and Snowdown, with precedence according to date of appointment; and six pursuivants, Kintyre, Dingwall, Carrick, Bute, Ormond, and Unicorn. Heralds and pursuivants are appointed by Lyon.

In Ireland also there is but one king-at-arms, Ulster. The office was instituted by Edward VI. in 1553. The patent is given by Rymer, and refers to certain emoluments as "prædicto officio . . . ab antiquo spectantibus." The allusion is to an Ireland king-at-arms mentioned in the reign of Richard II. and superseded by Ulster. Ulster holds office by patent, during pleasure; under him are two heralds, Cork and Dublin; and four pursuivants, Athlone, and St Patrick Nos. 1, 2, and 3. Ulster is king-at-arms to the order of St Patrick. He held visitations in parts of Ireland from 1568 to 1620, and these and other records, including all grants of arms from the institution of the office, are kept in the Birmingham Tower, Dublin, under the charge of the present most courteous and learned Ulster, Sir B. Burke. The precedence of the three chiefs has been the subject of dispute, but is now generally arranged, Garter being followed by Lyon, and he by Ulster.

Heraldry should be studied with reference to the period

in which it was a useful art, and in the simple examples of the 14th and 15th centuries. Before that period it was in a changing and elementary state; after it, it became merely ornamental, and its examples are complicated and debased. In a general treatise on the subject notice must of course be taken of the later as well as the earlier conditions of the art, but the greater number of the illustrations in the following pages are taken from the earlier and best examples.

A curious evidence of the vitality of heraldry, and of the desire of all mankind for ancestral distinctions, is afforded by its extension among the republics of the New World. The United States boast some excellent genealogical societies, and a great and very general desire is shown by individuals to trace their pedigrees to the stocks of the Old World, and to assume the arms proper to their name. The national emblem of the stars and stripes, now so widely and honourably known throughout the world, has been traced back to the paternal coat of the first and greatest president, George Washington, whose English ancestors bore "argent; 2 bars gules, in chief 3 mullets of the second." In Canada, Australia, and other English colonies, the assumption of arms by individuals and by the community is not less general; and the republics of South America, of Spanish origin, almost all have adopted coats of arms. The Peak of Teneriffe, the Beaver, the Red Indian, contribute to the list of charges, and the clear firmament of Chili is indicated by a star. "Coupé d'azur sur gules, à une étoile d'argent en abîme."

DIVISIONS OF ARMS.

Armorial bearings may be conveniently divided into those of dominion, of a community, of office, of concession, family or paternal arms, and arms of alliance. To these may perhaps be added arms of attribution. There is also another division, or rather peculiarity, called canting arms, of which many of the former divisions present examples.

1. *Arms of Dominion* are those of a kingdom or a feudal lordship. The origin of such arms is often obscure. Those of the Isle of Man are three legs conjoined in triangle at the thigh (fig. 116), probably borrowed from the emblem of Sicily, the ancient Trinacria, found upon Greek vases. The Irish harp is an emblem probably allusive to the instrument of Brian Boromhe. The origin of the lion of Scotland is also obscure, and of the tressure equally so, though fabled to be "First by Achaius borne."

Not unfrequently the arms of kingdoms were those of an early sovereign, adopted by succeeding dynasties to the exclusion of their own coat. The lions of England were certainly personal to the Plantagenet kings, if not to Henry I.; but they have become national to the exclusion of the arms of the Tudor, Stuart, Brunswick, and Saxon dynasties, just as neither the arms of Baliol, Bruce, nor Stuart ever became the arms of Scotland. The lion rampant azure, crowned gules, so long borne by the head of the German empire, belonged originally to the house of Hapsburg, and was not used by such of the early emperors as were not members of it; and the bend and ailerons of Lorraine only became a part of the arms of the empire after the marriage of Francis of Lorraine with Maria Theresa. It seems indeed to have been the custom of elected sovereigns, as those of the empire and of Poland, to place their paternal arms on a shield of pretence over those of the dominion. Cromwell so placed his arms over those of the commonwealth, and William of Nassau over those of England, but they disappeared with the individual who introduced them. On the other hand the arms of kingdoms and lordships are sometimes continued to be used as personal arms by the descendants of their former lords. The great shield of Mary of Burgundy quarters the arms of a number of

duchies and provinces. Simon de Montfort thus used the arms of the Honour of Hinkley. Richard de Monthermer (who married the countess of Gloucester, and was, by courtesy, earl of that name) at Caerlaverock, while he bore on his shield his own arms, "or, an eagle displayed vert," on his banner displayed "or, three chevrons gules" for the earldom. So also Humphrey, duke of Gloucester, (died 1446), used on one of his seals the three fusils of Montacute, because he held lands which belonged to that barony. The *Book of St Albans* says that, if the king grant a lordship to a yeoman entitling him to bear arms, he may take those of that lordship.

Under this head may be described the armorial shield of Great Britain (fig. 1). The arms, gules 3 lions passant in pale or, are for England, and are so borne by the kings of England till the reign of Edward III., who in 1340 quartered with them, in the first quarter, the arms of France, azure, semée of fleurs-de-lys or. Thus they continued till the latter part of the reign of Henry IV., when the fleurs-de-lys were reduced to three. No alteration occurred in the royal achievement during any of the succeeding reigns till the accession of James VI. of Scotland to the throne of England, when that sovereign introduced the royal arms of Scotland into the second quarter, and the arms of Ireland into the third quarter. The royal arms were thus borne by all the monarchs of the house of Stewart till the reign of Anne, though William III. bore over the quarterings of the royal arms those of his Dutch dominions—the house of Nassau. In the

FIG. 1.—Arms of Great Britain.

reign of Anne a change again took place, occasioned by the union of England and Scotland; and the arms of these kingdoms were impaled in the first and fourth quarters (England on the dexter, Scotland on the sinister); France was removed to the second; and Ireland retained its former position. On the accession of the house of Brunswick in 1714, the fourth quarter in the royal shield gave place to the arms of his Majesty's German dominions, an arrangement which continued till 1st January 1801, when, upon the Union of Great Britain and Ireland, the arms of France were excluded, England occupied the first and fourth quarters, Scotland the second quarter, and Ireland its old position in the third quarter; while over all, on an esutcheon of pretence, were placed the arms of Hanover, ensigned with the electoral bonnet, in 1816 exchanged for the Hanoverian crown. On the death of William IV. Hanover passed away, and its arms were withdrawn, and the present arrangement introduced. In Scotland, and in

Scotch official documents, the Scottish coat is placed in the first quarter. It bears "or, a lion rampant, within a double tressure flory-counterflory, gules." There is no positive authority for any early coat of arms being used for Ireland, though the bearing "azure, 3 crowns in pale or" granted by Richard III. to De Vere has been so regarded. From the reign of Henry VII., "azure, a harp or, strings argent," has been regarded as the Irish coat, and as such is inserted into the imperial shield. There is no authority of any standing for a coat of arms for the whole of the principality of Wales, but the coat usually attributed to it is "quarterly azure and gules, 4 lions passant gardant, counterchanged." The ancient princes of Wales would scarcely have adopted the lions of England. Moreover, this coat was never used by any leading chief in either middle or south Wales.

In Scotland arms territorial are much recognized. The dukes of Athole quarter Man. The garbs are quartered by the Erskines for the earldom of Bute. When Archibald Douglas was created duke of Touraine, he placed the arms of that duchy, three fleurs-de-lys, on his first quarter, before those of Douglas, Annandale, and Galloway. The dukes of Richmond bear three buckles for the dukedom of Aubigny. "Paly of 6 argent and sable" are the reputed arms of the earldom of Athole, and "a saltire between 4 roses" those of that of Lennox.

To this head belong arms of pretension, where a sovereign claims *de jure* a possession which he no longer holds, and sometimes never held, *de facto*. Thus the kings of England from Edward III. to George III. bore the French lilies, and claimed to be kings of France, and the kings of Sardinia and Naples used the arms of Cyprus and Jerusalem. In fact, nearly all the older sovereigns of Europe used arms of this character. The armorial shield of the house of Austria at the dissolution of the empire affords a number of curious examples of arms of pretension. Besides Hungary, Bohemia, Dalmatia, and Slavonia, it contained Aragon and Sicily, Brabant, Swabia, Antwerp, Flanders, Burgundy, Naples, Jerusalem, Lombardy, and Milan.

2. *Arms of Communities* are borne by corporations, religious houses, colleges, cities and boroughs, the cinque ports, guilds, and inns of court, some of which were allowed arms from an early period. These are very generally adopted in honour of some founder, great benefactor, or early and distinguished member of the body. Thus Birmingham bears the arms of the barons of that name, Manchester the Byrons, Leicester of the Bellomonts, Cardiff of the De Clares. Of religious houses Atherstone bore the arms of Basset; Garendon of the earls of Leicester; Kirby-Bellers of Bellers. Of colleges, Balliol, All Souls, and Pembroke at Oxford, and Clare at Cambridge, so commemorate Balliol, Chichele, Valence, and De Clare. The Cinque Ports all bear a part of the arms of England. The arms of the guilds and city companies usually contain some allusion to their trade; those of the grocers are 9 cloves; of the fishmongers, 3 dolphins; of the blacksmiths, 3 hammers. Of the inns of court, the Inner and Middle Temples bear badges of that order; Lincoln's Inn uses the purple lion of the De Laeys, earls of Lincoln; Furnival's Inn the bend and martlets of the Barons Furnival. A bishop, as a corporation sole, represents his see and bears its arms. These usually contain some ecclesiastical emblem, keys, crosses, mitres, martyrs' crowns, or the like. Hereford bears the arms of Cantilupe, possibly from its canonized bishop of that family. The arms of Lichfield and Coventry are founded upon those of Jerusalem; London, Winchester, and Bath and Wells assert their temporal power by bearing swords. The English sees were early provided with arms, but in Scotland they were of very late introduction. Bishops before the 17th century seem

to have used their personal arms. Thus Gawain Douglas, bishop of Dunkeld,

"Who gave fair Scotland Virgil's page,"

and Alexander Douglas, bishop of Moray in 1606, placed the Douglas arms upon their seals. Sometimes, however, this seems to have been combined with some ecclesiastical emblem, for the archbishops of St Andrews placed the cross of St Andrew on their seals, while below were their paternal arms, and the bishops of Glasgow so bore a figure of St Mungo.

3. *Arms of Office* are not uncommon. The electors and chief officers of the empire each bore some token of their office. The crossed swords so well known on Dresden china were borne by the electors of Saxony; the sceptre by those of Brandenburg; the crown of Charlemagne by the electors of Hanover as arch-treasurers. The ancestors of the dukes of Ormond were hereditary butlers of Ireland, and bore three covered cups. The kings-at-arms bear arms of office. Garter, the principal king, bears "argent, a cross gules, on a chief azure a crown or encircled with a garter of the order buckled and nowed between a lion of England and a lily of France," by no means such an example of heraldry as might be expected from the chief herald of England. The knights of St John of Jerusalem augmented their paternal arms with a chief gules, charged with a cross or. Several civic offices in France gave a right to bear arms. Ménage observed of a mayor of Angers who died upon his election, and was buried with his newly acquired arms—

"Il étoit de bonne nature,
Et ne fut armé qu'en peinture."

4. *Arms of Concession* were granted by a sovereign or some feudal superior, sometimes in memory of some great deed, but more frequently to indicate the connexion between the lord and his follower, when they are called arms of patronage. Of the former character was the heart in the arms of Douglas, first used by William I., earl of Douglas, 1356, in memory of James Lord Douglas's mission with Robert Bruce's heart; and to this a crown was added in the time of William II., earl of Angus, in 1617. Also the families of De la Warr, Pelham, Vane, and Fane bear arms in allusion to the share of the ancestors of each in the capture of John of France at Poitiers. Sir James Audley, after Poitiers, not only divided the Black Prince's present between his four squires, but allowed them to bear portions of his coat armour, "gules, a fret or," in memory of which the family of Delvea still bear "argent, a chevron gules, fretty or, between 3 billets sable" (fig. 82); and that of Dutton, "quarterly, argent and gules, on the 2d and 3d quarters a fret or." It was probably in memory of the same event that John Touchet, Lord Audley, granted to John and Thomas Mackworth, for services performed by their ancestors and themselves to his ancestors and himself, to bear "party dentelle de sable et d'hermine, un chevron de gules fretté d'or,"—arms still used by the Mackworths, with a slight addition, and now blazoned "per pale indented sable and ermine, on a chevron gules 5 crosses patée or." Among many similar instances may be mentioned Tatton of Cheshire, who bears "quarterly argent and gules," evidently derived from Massy. Harvey of Ickworth bears "gules, on a bend argent 3 trefoils slipped vert," derived from Foliot, who bore "gules, a bend argent." Staunton of Longbridge, who held by the service of repairing a tower of Belvoir Castle, bore "argent, 2 chevrons within a border engrailed sable," derived from Albini of Belvoir, who bore "or, 2 chevrons and a border gules." Lowther and Musgrave derive their annulets from Vipont. Moton of Peckleton, Brailsford, Astley of Hillmorton, Besington, bore "argent, a cinquefoil azure;" "or, a cinquefoil sable;" "azure, a cinquefoil ermine;" and "azure, a cinquefoil or,"

all derived from the bearings of the Bellomonts, "gules, a cinquefoil ermine." Hardress, who held under De Clare at Tonbridge, bore "gules, a lion rampant debruised by a chevron or;" and the lords of Avan, Welsh barons under De Clare, bore the three chevrons. Thus also Flamville and Wharton used the maunch of Hastings. "Ermine and checquy," from the Newburgh earls, were common in Warwickshire, and the "canton" in Westinoreland, derived from the Lancasters, barons of Kendal. In Douglasdale the "stars" of Douglas preponderate, and in Annandale the "saltire" of Johnstone.

Arms also passed from one friend to another by deed or will, even when there was no blood relationship. Henry de Lacy, the last earl of Lincoln, bequeathed to his friend and executor Sir H. Scrope a lion passant purpure, in augmentation of his coat, and Sir Henry wore it accordingly, though for life only. Maud Lucy, heiress of her brother Anthony Lord Lucy of Cockermonth, married Henry Percy, earl of Northumberland, 1414. She died childless, but bequeathed her lands to the Percys on condition they bore her arms, "gules 3 lucas," quarterly with Percy, which they continued to do, and indeed, though without any right, often styled themselves Barons Lucy. To this class also belong arms of augmentation, sometimes called additions of honour. Thus Richard II. chose to impale with his own the imputed arms of the Confessor, "gules, a cross patonce between 5 martlets or," and he granted to Thomas Holland, duke of Surrey, to impale them within a border argent with his own arms. Thomas Mowbray, duke of Norfolk, was also allowed to impale the entire arms of the Confessor, a fatal gift, as it was one of the charges brought against his ambitious descendant Henry Howard. Richard also allowed De Vere, duke of Ireland, to bear for life "azure, 3 golden crowns within a bordure," which seems then to have been regarded as the arms of Ireland. They are found on tiles marshalled quarterly with De Vere. After the victory of Flodden, Henry VIII. granted to the earl of Surrey to augment his arms with a "demi-lion gules pierced through the mouth with an arrow, within a double tressure flowered of the same," to be placed on the Howard bend. Henry used both the pile and the flaunc in his augmentations to the families of his English wives. Seymour bore "quarterly, 1 and 4, or, on a pile gules between 6 fleurs-de-lys azure 3 lions of England; 2 and 3, Seymour." The augmentation to Catherine Howard includes 2 flaunces, that to Catherine Parr a pale. Manners of Belvoir bore "or, 2 bars argent, a chief quarterly azure and gules, in the 1st and 4th quarter 2 fleurs-de-lys, in the 2d and 3d a lion of England, or." The bars were no doubt taken from the Muschampa. The chief and its contents were an augmentation from Henry VIII.

In Scotland an early Lord Seton had a concession from Robert Bruce of a sword supporting a crown, and his descendant in 1601 received as an augmentation "azure, a blazing star of 8 points within a double tressure or."

Most of the earlier grants or concessions seem intended to commemorate some territorial or genealogical concession, those of later date some connexion with royalty, or some deed of arms in the field. Thus Sir Cloudesly Shovel received 2 fleurs-de-lys in chief and a crescent in base in memory of two victories over the French and one over the Turks, and Nelson and other naval commanders received additions rather to be described as sea pieces than as heraldic augmentations.

5. *Family and Paternal Arms and arms of succession* are such as descend by custom to the male heir. The descendants of females, heiresses, save by special licence, can only quarter their arms. This rule has indeed been much abused, and on every side are seen good maternal names and arms adopted to the exclusion of those less dis-

tinguished on the paternal side. Paternal arms are of very various dates and origin. There seem, however, always to have existed certain recognized rules which the earl marshal had power to enforce. One of the most important of these was that no two persons in the same kingdom should bear the same arms, a practice clearly subversive of the main use of such insignia. Many were the disputes and challenges that arose out of this regulation, of which two of the most remarkable have already been mentioned.

6. *Arms of Alliance* or heirship were used when those of a great heiress were allowed to supersede the paternal coat. Thus the heiress of Mandeville, earl of Essex, married Say, and their heiress, Beatrice de Say, married Geoffrey Fitz Piers. Geoffrey (died 14 John) became earl of Essex, and their descendants took the name and bore the arms of Mandeville exclusively. William II., earl Warren (died 1148), left a daughter and heiress Isabel, who married Hamelin, natural son of Geoffrey of Anjou and brother to Henry II. He became earl of Surrey, and bore the name and arms and continued the line of Warren. The De la Bisse family, who claimed to descend from the male stock of the De Clares, bore the 3 chevrons differenced with a label of 3 points, though when, in the reign of Richard II., they intermarried with the Staffords, they laid this aside, and adopted "a chevron between three roses." When Gilbert Talbot (died 1274) married Gwennlian, or Gwendoline, the heiress of the Welsh prince Rhys ap Griffith, he laid aside his paternal coat, "bendy of 10 pieces, argent and gules," and adopted that of the lady, "gules, a lion rampant or, within a border engrailed of the field," as still used by the earls of Shrewsbury.

7. *Arms of Attribution* are altogether fictitious, and such as the heralds of the 15th and 16th centuries indulged in to an absurd extent, providing every hero of antiquity with a coat of arms. The same age that represented the Virgin Mary as versed in the canon law declared that Solomon, as the wisest of men, must have been a good herald, and described the armorial bearings of Achilles and Hector. Perhaps the most extravagant example of this fashion is contained in the work of Dame Juliana Berners, who says: "Of the offspring of the gentelman Japhet, comes Habraham, Moyses, Aron, and the profetys, and also the kyng of the right lyne of Mary, of whom the gentelman Jhesus was borne, very God and man; after his manhode King of the londe of Jude, and of Jues, gentelman by is modre Mary, prynce of coat armure;" and again, "The four doctors of holy church, Seynt Jeromy, Ambrose, Augustyn, and Gregori, war gentilmou of blode and of cotarmures." At an earlier period, in the reign of Richard II., it was believed that many of the bearings in use had been borne ever since the Conquest, as appears from the evidence in the Scrope and Grosvenor controversy. Almost all the older genealogists attribute coats of arms to ancestors long before they were in use. On the tomb of Queen Elizabeth are emblazoned the arms of William the Conqueror and Matilda of Flanders, and of Henry I. and Matilda of Scotland, all of course pure inventions. It is only of very late years, since a critical spirit has found its way even into heraldry, that these absurdities have been exposed.

8. *Canting Arms*, the "armes parlantes" of French heraldry, are common to all the preceding classes of arms, and most common in those of the earliest date. Such were the castle and lion for Castile and Leon, the fers de cheval of Ferrers, the lion (löwe) of Louvaine, the lucas of Lucy, the sharp-pointed row of fusils of Montacute, the corbeau or raven of Corbet, the herons of Heron, the falcon of Falconer, the greyhounds (levriers) of Mauloverer, the barnacles of Bernak, the castle of Chastil, the swin's head of Swinbourne, the penfeathers of Coupenne, the hirondelles of Arundel, the storm-fishes of Tempest, the hammers of

Hamerton, the tyrwhits of Tyrwhitt, the hanks of cotton of Cotton, the fusils of Trefusis, the oxen of Oxenden, the fer de moline of Molyneux, the hazel leaves of Hazlerigge, the Danish axes of Hakluyt, the bozons or bird bolts of Beltesham and Bozon, the bend wavy of Wallop, or Well-hope, the whelk-shell of Shelley, and many more, mostly early coats, and borne by considerable persons and families. In fact the practice was introduced whenever the name admitted of it, and sometimes when the allusion is very far-fetched indeed, as in the boar pig "verres," the crest of De Vere, and the cock for Law, alluding to his cry, cock-a-leary-law! Canting arms were equally common in other countries. In Italy the Colonne, Frangipani, and Ursini families bore a column, a piece of broken bread, and a bear. They were also common in France, Spain, and Germany.

TINCTURES.

Tinctures (in French, *émaux*) include metals, colours, and furs. The *Metals* are—

Or	Yellow	Topaz	Sol.
Argen	White	Pearl	Luna.

The *Colours*—

Azure	Blue, azur	Sapphire	Jupiter.
Gules	Red, gueules	Ruby	Mars.
Purpure	Purple, pourpre	Amethyst	Mercury
Sable	Black, sable	Diamond	Saturn.
Vert	Green, sinople	Emerald	Venus.

The *Furs*—

Ermine, Vair, Ermines or Counter-ermine.

Ermineo, Erminites, Pean, Vair-en-point, Counter-vair, Potent-counter-potent.

Gules is thought to come from the Persian *gul*, "a rose," but more probably from *gulo*, "the throat." The other terms are French. To the older colours have been added "sanguine" and "tenné" or tawny, a compound of red and yellow. They are almost unknown in English heraldry, and are symbolized, the one by sardonyx and dragon's tail, and the other by jacinth and dragon's head. The blazoning by precious stones and planets, and even by the virtues, was a foolish fancy of the heraldic writers of the 16th century, and applied to the arms of peers and princes. Gwillim condescends to use it.

A shield is rarely of one tincture only. In the roll of Caerlavrock, however, Sir Eurmenious de la Bretto

"La banière eut toute rougeate."

The original bearing of the Gournays of Norfolk seems to have been sable. De Bargo of Lorraine bore "azure." The Captal de Buch, who figures in Froissart as a Guyenne knight, bore "or," and Boguet, a Norman knight, bore "argent."

The furs (fig. 2) are all supposed to be formed of the skins of small animals fastened together. Ermine and vair were long the only furs acknowledged, and even now the rest are not common. Ermine (*a*) represents the skin of the animal of that name, and is white powdered with black spots.

In vair (*b*) the skins in shape resemble small escutcheons, the wings representing the forelegs and the point the tail. The fur is that of a sort of squirrel, bluish-grey on the back and white on the belly, and thence called "varus." The skins are arranged alternately argent and azure; and if of other colours they must be specified. There are varieties of vairs, as vair-en-

FIG. 2.—Furs.

point, where the point of one escutcheon is placed opposite to the base of that below; counter-vair (*h*), where those of the same colour are placed base to base and point to point. At first the vair was drawn bell shaped (*e*).

In ermines (*c*) the field is sable and the spots white, in ermine (*d*) the field or and the spots sable; pean (*f*) is the reverse, having golden spots on a black field. Erminites resembles ermine, save that the two lateral hairs of each spot are red. This fur, however, is seldom if ever used in English heraldry. Guillim in blazoning a fur prefixed the word "purled."

Potent (*i*) is a variety of vair, and often blazoned as "vair-potent." There is also a form of it called "potent-counter-potent" (*g*). Manchester, of the county of Stafford, bore "potent-counter-potent, argent and sable, a bend gules." The escutcheons or skins are T-shaped, and resemble a "potence," that is, a gallows or a crutch head.

Ermine and vair are used almost to the exclusion of all other furs. Even ermine is very rare.

The dukes of Brittany, earls of Richmond, bore "ermine" (this was the coat of John de Montfort, duke of Brittany, whose widow married Henry IV.); Lattin, "per pale argent and sable, a saltire engrailed ermines and ermine;" Beauchamp (old), "vair, a label gules;" Gresley of Drakelow, "vair, ermine and gules;" Calvert, "paly of 6 ermine and pean, a bend engrailed counterchanged."

Of the colours, gules, azure, and sable are by far the most common in early bearings. They contrasted strongly with each other and with the metals. To preserve this contrast, arose the very early and general rule not to place metal upon metal, or colour upon colour. Scott takes the licence of a poet to break this rule in *Marmion*, whose falcon "Soar'd sable on an azure field,"

and in *Ivanhoe*, where the black knight bears "a fetter lock and shackle bolt, azure, on a field sable." He pleasantly detenned himself by quoting the arms of the kingdom of Jerusalem, "argent, a cross potent between four crosses, all or," which thus violates this fundamental canon. The French call such coats "armés à enguernis." There are a few other less illustrious but early instances.

Venour, warden of the Fleet, 1480, bore gules on a fess sable, five escallops or, 2, 2, 1.

Leycester of De Tabley: azure, a fess gules between three fleurs-de-lys or.

Sir Richard de Rokesele, temp. Edward II.: "d'azure, a six lioncels d'argent, a une fesse de gules."

When an object is given of its natural colour it is blazoned as "proper." Thus in the insignia of the order of St George and St Michael we have "the archangel encountering Satan, all proper;" though the German family of Teufel displays a teufel or devil gules. A very striking contrast of colour is produced by a process called "counterchanging," where a shield is divided between two colours, and a charge placed over the dividing line is also divided between the same colours transposed.

Chetwode of Chetwode: quarterly, argent and gules, four crosses patée counterchanged.

Payto of Chesterton: barry of six party per pale dancette, argent and gules counterchanged.

A very convenient practice of representing the tinctures by certain marks and lines arose in the 16th century, and is attributed to Padre Silvestre de Petro Sancto, an Italian. It was devised to allow of the representation of armorial bearings in drawings or engravings where it was inconvenient to colour them. Planché states the earliest known instance of the use of this method in England to be in an engraving of the seals of the regicides attached to the death warrant of Charles I. Sir E. Bysshe in Upton, 1654, gives a representation of these marks. Or (fig. 3) is represented by hatched points; silver is plain; azure is represented by horizontal lines, gules by vertical lines; those for purpure are drawn diagonally from sinister to dexter,

and those for vert from dexter to sinister. For sable, the lines are vertical and horizontal; for sanguine, diagonal.

FIG. 3.—Representation of Tinctures. *a*, or; *b*, argent; *c*, azure; *d*, gules; *e*, purpure; *f*, sable; *g*, vert; *h*, sanguine; *i*, toné.

or in saltire, from right to left and left to right, a compound of purpure and vert; and for tenré, diagonal from sinister to dexter, and horizontal, a compound of purpure and azure.

PARTS OF ARMS.

These are (1) the escutcheon; (2) the ordinaries; (3) partition lines; (4) charges.

The Escutcheon.

The *Escutcheon*, écn, or shield, called in blazon the field, upon which all lines are drawn and charges delineated, represents the shield borne in war upon which the arms of the knight were displayed. The figure of the shield varied in heraldry as in war. First came the long-pointed, kite-shaped shield or "pavese," slightly convex, and used with chain armour. As late as the reign of Richard I. and John such may be seen on early effigies, commonly but by no means always without armorial bearings, which were not then generally in use (fig. 4). Varieties of this are the heart-shaped or pear-shaped shields (fig. 5), and sometimes a shield representing a third part of a cylinder with square top and bottom, much used in siege operations. Early in the 13th century was introduced the small heater-shaped shield, also triangular but narrow, short, and somewhat lancet-shaped. This was in use in the reign of Henry III., and in the Early English period of architecture (fig. 6). The three water budgets of Ros appear on a shield of similar form of the date of Edward I. in the Temple Church (fig. 7). As coats

FIG. 4.

FIG. 5.—From the Budgets of Ros.

FIG. 6.

FIG. 7.

FIG. 8.

of arms were then simple, this shield was large enough to contain them without crowding, and therefore with sufficient distinctness. When drawn or carved in architecture it is suspended by its "guiges" or shield straps, either upright or by the upper sinister angle, when it is said to be "couché." Fig. 8 is from the great seal of Thomas de Beauchamp, earl of Warwick, and shows the form of shield in use during most of the Edwardian period.

As fluted and fancy plate armour came into fashion, the shield also altered its figure and became four-sided, and concave in the top and side edges, with a central point below; a notch also was cut in the upper dexter corner to

allow the lance to reach its rest, which projected from the breastplate, as in the shields upon the tower of the chapel of the Babingtons at Detlick, and on their tombhouse at Kingston (fig. 9). Such shields were called "chaneréc," or "à la bonche." They are frequently carved as an ornament in the Perpendicular style of architecture. As the shield ceased to be used in war, and was only known as a representation upon tombs or in pedigrees, it was altered to suit the fashionable practice of introducing large numbers of quartered coats, frequently twenty or thirty, and sometimes a hundred, as in an escutcheon of the earls of Huntingdon in Burnham church.

Fig. 9.

In the construction of the shield, while actually used in war, great strength had to be combined with as much lightness as possible, and this was attained by the use of cuir-bouilli and plates of horn stretched upon a wooden frame. The cramps and cross pieces employed to stiffen the whole are sometimes seen upon early shields, and are supposed, with much reason, to have been painted or gilded as ornaments, and to have given rise to the bars or ordinaries which predominate in the first simple coats. Our acquaintance with the forms and fashions of the earlier shields is chiefly derived from their representations on tombs, but the actual shield of John of Gaunt was long preserved in old St Paul's, and that of the Black Prince still hangs above his tomb at Canterbury, as do those of his father and of Henry V. at Westminster. An unmarried woman did not place her arms upon an escutcheon, but, whether maiden or widow, upon a lozenge, an early practice in allusion probably to a fusil or distaff. When married she shared the shield of her husband.¹ The lozenge is an ancient usage, being found in the seals of English ladies of the middle of the 14th century, and in Scotland a century later. In modern heraldry the shields of knights of an order are usually oval or circular, called "cartouche" shields, and encircled with a ribbon bearing the motto of the order. When married the knight's arms are blazoned alone within the ribbon, and again represented with those of his wife in a second shield encircled with a plain ribbon, and placed on the sinister side of the other. The dexter side of the escutcheon is that on the proper right of the bearer and therefore on the left of the spectator.

To secure due precision in blazoning, nine points, indicated by as many names, are taken on the surface of the shield. These (represented by the letters in fig. 10) are—at the top in a horizontal line three, the middle, dexter, and sinister chief; at the base three, also horizontal, the middle, dexter, and sinister base; and in the central or vertical axis also three, of which the upper is the honour point, the lower the nombril point, and the middle the fess point—the central point of the shield. The last three are of course in a line with the chief and base middle points.

Fig. 10.

Before passing to the ordinaries, it will be convenient here to mention a species of decoration applied to the shield, which, though not strictly heraldic, is often used in early heraldry and called "diaper." A shield "diapered," "bracteatus," is covered with a ground pattern usually in squares or lozenges with a flower or scroll work in each

compartment. The idea is said to be copied and named from the linen cloths of Ypres. An often-quoted example of diaper, and a very good one, is the shield of Robert de Vere upon his tomb at Earls Colne (fig. 4). Also the shield of William de Valence upon his effigy in Westminster Abbey is a very fine example of diaper. There the ground is divided into small squares, and each contains a pattern. The row of shields in the tabernacle work of the old chapel of St Stephen's, Westminster, exhibits some fine specimens of diapered work in squares, lozenges, and circles. The shield of Earl Warren at Castle Acre Priory is a good example of diaper, as is the counterscal of Thomas le Despenser affixed to a Kenfig charter in 1397 (fig. 11).

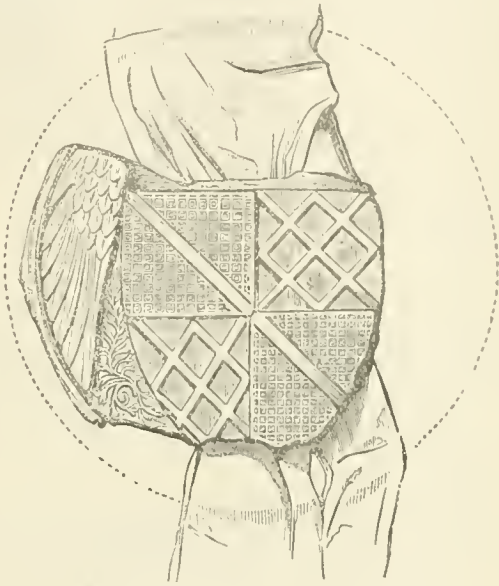

Fig. 11.—Counterscal of Thomas le Despenser.

Ordinaries and Partition Lines.

The *Ordinaries*, or, as they are called in most heraldic books, "the honourable ordinaries," have been supposed to represent the clamps or fastenings of the shield, converted into ornaments by painting or gilding. They may be regarded as nine in number—the chief, the pale, the fess, the chevron, the bend, the cross, the saltire, the pile, and the quarter. When charged they are drawn somewhat broader than when blank, and each has one or more diminutives. All were more or less in use in the earliest times of heraldry, and they were then drawn more boldly and narrower than is now the custom. When such of the ordinaries as admit of it are cut short so as not to reach to the margin of the field, they are said to be humettée or coupée.

Partition Lines, closely allied to the ordinaries named from them, are the lines by which shields may be divided, and which vary both in direction and pattern. It will be convenient to notice these before proceeding to a detailed account of the ordinaries, as the partition lines will be constantly referred to in the examples. When the field is divided in the direction of an ordinary it is said to be "party per" that ordinary, as party per fess or per bend. Party per chief is rare, party per pile or per quarter unknown; party per cross is called quarterly; party per cross and per saltire is gironny. When the partition line is mentioned without qualification, it is a straight line, but it may be broken in a variety of ways, as indented, dancette, engrailed, invected, undy, nebuly, embattled, dove-tailed, and raguly. These partition lines in some cases, and not in all, have arisen from the outline of a charge or bearing. Thus Charnels of Snareston at first bore eleven

¹ When an eminent geologist and proprietor of a well-known patent lozenge left his business for the militia, and after a short time returned to civil life, it was said—

"So maidens who to Hymen yield
Exchange the lozenge for the shield,
But, when they lose the best of men
Return to lozenges again."

lozenges conjoined in cross, which at a later date became a cross engrailed, and fusils in the same way became converted into dancette. In English heraldry the partition lines are per pale, per fess, per chevron, per bend dexter and sinister, quarterly, per saltire, and gyronny.

The annexed shield (fig. 12) represents these partition lines. It may be blazoned—quarterly of nine coats: 1. Butler: or, a chief indented azure; 2. Fleetwood: party per pale nebuly, azure and or, six martlets counter-changed; 3. Vavasour: or, a fess dancette sable; 4. — or, a chevron inverted azure; 5. Boyle: party per bend embattled, argent and gules; 6. Trevor: party per bend sinister, ermine and ermines, a lion rampant or; 7. Lawrence: argent, a cross raguly gules; 8. Bottetourt: or, a saltire engrailed sable; 9. — party per fess dovetailed, or and sable. A good example of a cross raguly, not an armorial bearing, is found upon a 12th century tomb in the church of Llanfihangel-yu-Gwynfa in Powsland.

Fig. 12.

The French use *parti* and *coupé* for per pale and per fess; they do not part per chevron, but per bend and per bend sinister are *tranché* and *taillé*; quarterly is *écartelé*, and per saltire *écartelé en sautoir*; gyronny is *gironé*. Besides these the French have a number of other divisions, as "terce," when the shield is divided into three parts, as "terce en pal, terce en fasce, &c. Terce en pal is convenient when the coats of two wives are to be marshalled on the husband's shield.

Formerly such broken lines as were used were not mere margins, but affected the whole ordinary; a fess indented was a zigzag and called a *daunce* or *dancette*. This practice is still preserved with the line undy. A bend undy or wavy is not a mere bend with a wavy edge, but the whole bend is in waves, whereas a bend nebuly or raguly has merely a particular kind of edge.

Returning to the ordinaries, it may be remarked that very many both of these and of the subordinaries in heraldry are very frequent constituents in mouldings in the Norman style of architecture. The chevron and the billet are amongst the most common. The roundel forms the hood moulding of a door at Peterborough, and is inserted in a moulding in the intersecting arches of St Augustin's, Canterbury. The fret, the billet, and the roundel or pellet are largely used in the oldest parts of Malmesbury, and on Lincoln tower is a good example of undy,—and this before the regular employment of heraldic bearings.

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

1. The *Chief*, *chof*, *caput*, is the upper part or head of the shield, covering one-third of it, and parted off by a horizontal line. It is found in the earliest examples of arms. In the roll of Henry III. it occurs fourteen times, in that of Edward II. twenty-one times.

De Vivonne. ermine, a chief gules (fig. 13).

Butler (see fig. 12).

Astoa: argent, a chief undy (fig. 14).

St John of Melchbourne: argent, on a chief gules, two mullets pierced or (fig. 15). Cromwell of Tattershall: party per chief, gules and argent, a bend azure (fig. 16); which might also be blazoned as gules, a chief argent, and a bend azure (fig. 16).

Heraldic writers give the *fillet* as a diminutive of the chief. It was a narrow strip laid upon the chief, a little above its lower margin. Guillim mentions, but gives no examples of it.

2. The *Pale*, *pal*, *palus*. is a vertical strip set upright in the

middle line of the shield, and one-third of its breadth. One of its earliest examples, if indeed it be not a mere gilt ornament, is ascribed to Graintmainsel, baron of Hinkley, who is reported to have borne gules, a pale or; but the banner of the barons of Hinkley carried by Simon de Montfort was per pale indented, gules and or. The "sable pale of Mar" is the well-known bearing of Erskine, argent, a pale sable (fig. 17), but when it was introduced into Scotland is not clear. In the roll of Henry III. there occurs no pale, but there are three examples of paly. Party per pale is also there found. In the roll of Edward II. there is also no pale, but paly or party per pale occurs thirteen times. The latter is called simply "party":—Pluys, "party d'or et goules."

Fig. 17.

Fig. 18.

Fig. 19.

Fig. 20.

The diminutives of the pale are the *pallet*, one-fourth, and the *endorse*, one-eighth, of the breadth of the pale, both unknown anciently. The pallet may be used singly, the endorse only in pairs, one on each side of the pale.

Waldgrave: per pale or and gules.

Marshall, Earl Marshal and of Pembroke: party per pale or and vert, a lion rampant gules.

Fleetwood (see fig. 12).

When the pale is repeated, it is blazoned as "paly," and the number of pieces specified.

Kingdom of Aragon: paly of ten argent and gules (fig. 18).

Gurney: or, two pallets azure.

Wykes of Dunsley: argent, on a pale endorsed sable three greyhounds' heads crased or, collared gules (fig. 19).

Daniel of Cheshire: argent, a pale fustilly sable.

Lightford: azure, a pale rayonné or (fig. 20).

Fig. 21.

Fig. 22.

Fig. 23.

3. The *Fess*, *fesse*, *fascia*, is a strip placed horizontally across the middle of the field. It occurs about twenty-five times in the roll of Henry III., and its diminutives about twenty-three times, or forty-eight times in all, against ninety in the roll of Edward II.

Hapsburg: gules, a fess argent (fig. 21).

Chailotte, queen of George III., on her shield of Mecklenburg-Strelitz placed a scutcheon of pretence party per fess, gules and or, for Stargard.

Vavasour (see fig. 12).

Henry de Percy, ancient blazen: azure, a fess engrailed or (fig. 22). This is a way of describing what is better known as azure, five fusils conjoined in fess or.

The seal of Walter son of Alan, steward of Scotland, 1190, gives a fess chequy, probably the earliest trace of the Stewart coat.

Weld of Lulworth: azure, a fess nebuly between three crescents ermine (fig. 23).

De le Plaunch: argent, a fess embattled gules.

Paramour: azure, a fess embattled counter-embattled, between three estoiles or. The Temple banner "Beauseant" was party per fess sable and argent.

Nicholas de Oriel: per fess or and gules.

Swinburne (modern): party per fess gules and argent, three cinquefoils counter-changed.

Pearston: argent, a fess, quarterly, sable and or (fig. 24).

The diminutives of the fess are the *bar*, covering one-fifth of the field; the *barrulet*, one-half, and the *closet*, one-quarter of the bar. The closet is used in pairs only, usually called *gemelles*, and these are sometimes quadrupled, two pairs on each side, and sometimes are used without the bend between them. The bar is rarely used singly, the number must be specified if above four, when the coat is "barry" of the given number. The term *fessy* is not used.

Harcourt of Ankerwyke. gules, two bars or.

Basset of Tehdy: or, three bars wavy gules.

Elount: barry nebuly of eight pieces, or and sable.

Fitz Alan of Bedale: barry of six, argent and azure.

Dabridgecourt: ermine, three bars humetty gules, fesswise in pale.

Badlesmere: argent, a fess gemelled gules (fig. 26). This is from the roll of Caerlarrow, but the more used blazon is—argent, a fess and two bars gemelles gules, which might be given—a fess closeted.

Fairfax of Denton: argent, three bars gemelles gules, surmounted by a lion rampant sable, crowned or.

Huntercombe: ermine, two pair of gemelles gules.

Edmondson and some other writers describe the gemelles as cotises.

4. The *Chevron*, *cheveron*, *canterius*, from whatever source derived, seems to have been named from its resemblance to the main rafters or principals of a roof, a familiar sight in early buildings. It is common to find orders on the royal foresters for so many pairs of chevrons. Mr Planché points out that in the earliest English examples of this ordinary, in the seal of Gilbert, earl of Pembroke, in the reign of Stephen, the upper edge of the shield is pointed like a ridged roof, and the chevrons are parallel to it, and divide the

shield into thirteen spaces. He regards as a part of the structure of the shield these chevrons, afterwards reduced to three and used as a regular heraldic bearing by the house of Clare. The chevron occurs six times in the roll of Henry III., and the chevrouel, its diminutive, nine times. The two occur ninety-two times in the roll of Edward II. In breadth it is one-fifth of the shield. Its diminutives are the *chevronel* or *étage*, of half, and the *couple-close*, of a quarter its breadth. The latter is borne in pairs above and below the chevron. When the chevron is repeated up to three they may be chevrons or chevronels. If exceeding that number the bearing is chevronny, unless the number be specified. The chevron is still used to denote the rank of the non-commissioned officers of the British army, but of late years has been borne by them inverted.

Stafford: or, a chevron gules (fig. 26).
 Marler: a chevron purpure, in dexter canton an escallop sable.
 Fettiplace: gules, two chevrons argent.
 Clare: or, three chevrons gules (fig. 6).
 Wyvill of Constable-Burton, derived from Fitz Hugh: gules, three chevrons brazed vair, and a chief or (fig. 27). [Brazed is interlaced.]
 Kniveton: gules, a chevron party per chevron neboly, argent and sable (fig. 28).
 Fitz Walter: or, a fess between two chevrons gules (fig. 29).
 Hungerford: per pale indented gules and vert, a chevron or (fig. 30).
 Hotot: azure, a chevron couple-closed or, between three crescents argent (fig. 31).
 Newport on Usk commemorates the Staffords, its ancient lords, by bearing a chevron reversed (fig. 32).

5. The *Bend*, *bande*, *balteum*, is a strip extended upon the shield from the dexter chief to sinister base, and in breadth one-fifth of the field. The diminutives are the *bendlet*, half the bend, and the *cotise*, or cost, a fourth part, borne in pairs, flanking the bend; and the *ribbon*, one-eighth of the bend. The ribbon is used as a difference, and is sometimes coupé or cut short, when it becomes a *bâton*, and is the French *barre*. The *bâton* often marks illegitimacy. The term *bâton*, however, is also applied to the ribbon.

Serpote of Danby: azure, a bend or; a very celebrated example of the bend (fig. 32).
 Calpeper: argent, a bend engrailed gules.
 Wallop of Farleigh-Wallop: argent, a bend wavy sable (fig. 34).
 Fortescue of Castle-Hill: azure, a bend engrailed argent, cotised or.
 Clopton: sable, a bond between two cotises dancette or (fig. 35).
 Bayly: party per bend embattled, argent and gules (see fig. 12).
 Byron of Rochdale: argent, three bendlets enhanced gules (fig. 36).
 Mootford: bendy of ten, or and azure.
 Chaucer: per pale argent and gules, a bend counterchanged (fig. 37).
 Fitz Herbert of Noibury: argent, a chief vair, or and gules, over all a bend sable.
 Widdrington: quarterly, argent and gules, a ribbon sable (fig. 38).
 Sir Hugh Baden: argent, on a bond double cotised sable three eagles displayed palewise or.
 Keck of Stoughton: sable, a bend ermee between two cotises, flosy counterfory, or.

The *Bend Sinister* is a variety of the bend drawn from the sinister chief to the dexter base. Its diminutives are the *scraye* or *scarp*, half the breadth, and the *ribbon* or *bâton sinister*. A bend sinister

¹ This is called also crenellated, and in French *bréteasé*, from the *bréteas* or wooden gallery attached to the battlements of castle walls. When embattled on both faces the piece is said to be "embattled counter-embattled." The notch in a parapet is an embrasure, the intermediate piece of masonry a merlon. When a second and a smaller merlon is placed on the first, the battlement is said to be copped.

is a rare bearing, and, with its diminutives, is frequently used to express illegitimacy, especially the *bâton*, though sometimes as a difference only.

Richard de Bury, bishop of Durham: party per bend sinister, or and azure, a bend counterchanged (fig. 39).
 Trevor (see fig. 12).
 The dukes of Orleans: azure, three fleurs-de-lis or, a bâton argent (fig. 40).

6. The *Cross*, *croix*, *crux*, needs no description save that in heraldry it is usually the Greek cross, or that of equal arms. The breadth is one-third of the shield. It is an early and very common bearing, and whatever its origin it speedily became identified with the emblem of Christianity, and was popular throughout Christendom—

"Crux mihi certa salus, crux est quam semper adoro,
 Crux domini mecum, crux mihi refugium.
 Per crucis hoc signum fugiat procul omne malignum."

When plain it is blazoned only as "a cross." Thus the cross of St George is "argent, a cross gules," and the statutes of the Temple direct each knight to wear a red cross upon his "cotte d'armes," on breast and back. As a plain cross it occurs six times in the roll of Henry III., and in its varieties eleven times, and in the roll of Edward II. these numbers have risen from 17 to 102, when it was the most popular of the ordinaries.

De Burgh of Ireland: or, a cross gules (fig. 41).
 Duckenfield of Duckenfield: argent, a cross pointed wavy sable, voided.
 Ufford: sable, a cross engrailed or (fig. 42).

A seal of John de Ufford, probably about 1360, bears on a heater shield what would now be described as eight fusils conjoined in cross, and which is an early form of the Ufford coat. There is also a mullet in dexter canton, possibly to mark a younger branch.

Colley: argent, a cross wavy, voided, sable (fig. 43).
 Skirlaw, bishop of Durham: argent, six willow wands interlaced in cross sable, in allusion to his father, who was a basket-maker (fig. 44).
 Lawrence (see fig. 12).

Party per cross or quarterly is an early and popular bearing.

Say: quarterly, or and gules (fig. 45).
 Lacy: quarterly, or and gules, a bend sable.
 Fitz Warin: quarterly, per fess indented, argent and gules.
 Atkins of Saperton: argent, a cross sable, bordered with half fleurs-de-lis, between four mullets, sable.
 Lorraine of Kirkharle: quarterly, sable and argent, a cross counter-quartered of the field.

When the central square of the cross is removed, it is said to be quarter-pierced, a cross quarter-pierced.

The varieties of the cross are almost innumerable. Edmondson gives 107 of them, and there are many more. Of these it will be sufficient to notice those comparatively few that are older and in general use; as the cross bottonny, the cross crosslet, the cross flory, moline, patée, patonce, potent, rocerellee, and voided. None of these varieties extended to the margin of the field. When a plain cross does not so extend it is blazoned as coupé or humetty.

The cross bottonny, trellée, or modulata has each limb capped by a trefoil, or sort of button.

Northeys of Pynes: argent, three crosses bottonny sable, palewise in bend (fig. 46).

The cross crosslet has its extremities crossed. It is usually borne as a charge in numbers, but not always.

Westerley: argent, a cross crosslet sable.
 Beauchamp, earl of Warwick: gules, a fess between six cross crosslets or (fig. 8).
 When the lower limb is uncrossed and pointed it is "fitchy."

Belgrave: argent, a cross patée fitchy sable (fig. 47).

The cross patée was the emblem of the Knights of St John, and is known as the "Croix de Malthe." The cross patonce has expanded ends like the cross patée, but each terminates in three points. Patée and patonce were not always distinguished. At

Caerlarrow Latimer is described as bearing a cross patée, whereas the regular coat of the family was gules, a cross patouce or. Wm. de Fortibus, before 1241: gules, a cross patouce vair (fig. 48).

The cross flory or fleurette is capped in a similar way by fleurs-de-lys.

Lamplugh of Lamplugh: argent, a cross flory sable (fig. 49).
Richard Suwart or Sward at Caerlarrow bore sable, a cross flory argent.

The cross moline is so called from the fer de moline, or millrind, the iron clamp of the upper millstone. When the millrind itself is borne it is pierced, but the cross moline is not necessarily so. Its extremities are split, curved outwards, and cut off square. It is an early bearing. When pierced this must be specified.

Bee of Eresby: gules, a cross moline argent.
Molyneux of Selson: azure, a cross moline quarter-pierced or (fig. 50).

The cross potent, potence, or crutch or gibbet headed, has its extremities T-shaped.

An early example is seen in the arms of Jerusalem, argent, a cross potent between four crosslets or (fig. 51). Originally, however, the arms of the cross ended in knobs like the handles of a pilgrim's staff, thence called "bourdonnée."

The cross recerclée has the ends split and curled outwards, but differs from the cross moline in having them pointed. The two bearings were occasionally confounded, and while the Baron Bee bore a cross moline, Bishop Antony Bee, his brother, is described as bearing a cross recerclée.

The cross voided is the outline only, called by the French "un croix faux;" the field is seen through it. The cross recerclée is usually also voided.

The lords of Crevecoeur bore "d'or, ung faux croix de goules, recerclée" (fig. 52).
Basing, temp. Edward III.: azure, a cross recerclée and voided or.

Fig. 50.

Fig. 51.

Fig. 52.

Fig. 53.

The cross formée is peculiar among these varieties, inasmuch as its extremities reach the edge of the field. In other respects it resembles the cross patée.

Lawley of Spoonhill: argent, a cross formée chequy, or and sable.

Among the other, later, and but little used varieties of the cross may be mentioned the avellane, ending in filbert husks; the cross anchored, of which the limbs terminate in anchors; the cross of the crucifixion or of Calvary, mounted on steps. A cross with a narrow border of another colour is "fimbriated"; a cross pointed is where the ends are so cut.

7. The *Saltire*, saltier, or saintoir, is known as the cross of St Andrew, and is a common constituent in Scottish coats of arms. The origin is said to be a sort of stirrup or crossed loop suspended from the saddle by the aid of which the knight leaped into his seat. Such a stirrup certainly appears on the steed of Patrick, earl of March, on his seal, and on the seal of an early Despenser, and this is the only suggestion that accounts for the name. The saltire is in breadth one-third of the field.

The Scottish emblem is azure, a saltire argent; that of St Patrick, argent, a saltire gules. Neville bore

"A silver saltire upon martial red."

that is, gules, a saltire argent (fig. 53).

Bottetout: or, a saltire engrailed sable (fig. 12).

Gaga: party per saltire, argent and azure, a saltire gules (fig. 54).

Glanville of Catchfrench: azure, three saltires humetty or (fig. 55)

Bruce: or, a saltire and chief gules.

Fig. 54.

Fig. 55.

Fig. 56.

Fig. 57.

Common charges placed upon a horizontal or vertical ordinary, as a fess or chief or cross, are placed upright; if on an inclined ordinary, as a bend or saltire, their position should be specified; if upright, they are palewise; if inclined, bendwise or saltirewise. On the chevron they are upright unless otherwise specified.

Dalrymple: or, on a saltire azure nine lozenges of the first (fig. 56).

Here the charges slope with the limbs of the saltire, that in the centre being upright. The deanery of Hengham, dedicated to St Andrew, bore on its seal a saltire raguly. The saltire has no regular diminutives, but when several are borne they are coupé.

8. The *Pile*, pieu, pila, is a triangular strip, its base one-third of the breadth of the shield, and usually applied to its upper margin, the point coinciding with the lower point of the shield. It has been

derived from the Roman *pilum*, a military weapon, and from the *pila* of the engineer. The origin is obscure, but it is a very early bearing. It has no diminutive.

Sir John Chaundos, as Froissart often tells us, bore "d'argent, a ung peel de goules, e un label d'azure" (fig. 57), and his ancestor Robert, temp. Henry III., bore or, on a pile gules three estoiles, between six of the same, counterchanged, an unusually complicated bearing for that age.

Waterhouse: or, a pile engrailed sable.

Frequently more piles than one were used, generally three, when they are to be blazoned as meeting in base.

Holles: ermine, three piles sable meeting in base (fig. 58).

Hulse: argent, three piles sable, one issuant from the chief between two from the base.

When the base of the pile is applied to any other part of the shield than the chief it must be specified. The pile was used by Henry VIII. as a vehicle for some of his grants of augmentation.

9. The *Quarter* or *franc-quarter* covers the upper dexter quarter of the shield. If placed in the sinister quarter, this must be specified. Its diminutive is the *canton*, of two-thirds its area. Both are early bearings, but in the roll of Henry III. the quarter appears in several coats which in later rolls are blazoned with the canton. Both are frequently charged. When either occurs in conjunction with another ordinary or subsidiary, they are placed above it, and therefore blazoned after it, as further from the field. Both are used as early differences, as in the families of Zouch and Basset, and both are always borne with straight edges. A canton is also called a corner, and a cross between 4 crosses is said to be cantoned of them.

De Clare (old): or, a quarter gules (fig. 59).

Sturley of Easington: pale of six or and azure, a quarter ermine.

Sutton of Narwood: argent, a canton sable.

Samuel Clark, the martyrologist: gules, a fleur-de-lys or, a canton ermine (fig. 60).

Fig. 59.

Fig. 60.

Fig. 61.

Subordinate Ordinaries.—These are the border, the inescutcheon, the orle, the tressure, the fret, the gyron, the flasque, the lozenge, the fusil, the mascle, the rustre, the roundel, guttes or drops, the billet, and chequy.

The *Border*, bordure, fimbria, or limbus, though a very old and independent bearing, was frequently used as a difference, and occasionally as a mark of illegitimacy. It is what its name expresses, and its breadth is one-fifth of the field. When used in an impaled coat the border is not continued round the inner side; in fact it is dimidiated. In old examples this was not always attended to. In a quartered coat the border is borne complete.

Sir Perdas d'Albret, temp. Edward III.,

"Who guly shield about his neck did bring,
Wrought with dent bordure, silver shining,"

bore "gules, a border indented argent."

Rondell: ermine, a border compoy, or and sable (fig. 61).

Hamelin, illegitimate brother of Henry II., seems to have borne around his arms, on a border gules, eight lions passant or. This was before quartering came into use. The augmentation granted by Henry VIII. to Courtenay, marquis of Exeter, was a border quarterly of England and France, the fleurs-de-lys and lions entury, or in orle (fig. 62).

Fig. 62.

Fig. 63.

Fig. 64.

The *Inescutcheon*, or *écusson*, is a small shield borne within and upon the greater one. It occurs in the earliest coats, and when voided becomes an orle.

Mortimer: barry of 6 or and azure, an inescutcheon argent, a chief of the first pale of the second between two gyrons of the same (fig. 63).

Rokeley: ermine, an inescutcheon azure.

Allestree of Allestree: argent, a chief azure, on a bend gules three inescutcheons party per chief, vert and argent (fig. 64).

The arms of Maxwell, Lord Herries and earl of Nithsdale, afford a good example of this subsidiary. They are, argent, an eagle displayed sable, beaked and membered gules, surmounted with an inescutcheon of the first, charged with a saltire of the second, surcharged with a hedgehog or, for Herries.

The *Orle* is the edge or hem, orlet, of the inescutcheon, voided, and is therefore blazoned by the French as a false escutcheon.

Joh de Baitol: "De goules, ovo ung faux cecochon d'argent," that is, "gules, an orle argent" (fig. 63).
 Wunnington of Stanford: argent, an inescutcheon voided, within an orle of martlets sable (fig. 66).

Fig. 64. Fig. 65. Fig. 66. Fig. 67.

The *Tressure* is in fact a narrow orle, almost always borne double, and usually flowered. It is a favourite Scottish bearing, and is set with fleurs-de-lys placed alternately, the upper and the lower half on each face of the tressure, when it is blazoned "flory-counterflory." This, in the Scottish royal arms, is said to denote the early alliance between that country and France. The bearing is, or, a lion rampant within a double tressure, flory-counterflory, gules (fig. 67). The tressure was a common grant of augmentation from the crown for services or in memory of an alliance. Scott of Thirlstane had it from James V. and bore or, a bend azure, charged with a mullet pierced, between two crescents of the first, the whole within a double tressure flory-counterflory of the second—

"The tressured fleurs-de-lys he claims
 To wreath his shield."

The *Fret* was originally borne fretty, representing a trellis. The single fret is very rare in ancient arms, but many of those families who at first bore fretty afterwards bore a fret. Fretty is usually composed of eight pieces.

Maltrovers: sable, fretty or, which soon became and continued sable, a fret or (fig. 68).

When nailed at the joints it is said to be *clouée*.

Trussel: gules, a trellis (fretty) clouée or.
 Harrington: sable, a fret argent, called also a Harrington knot (fig. 69).
 Vernon of Sudbury: argent, a fret sable.

The *Gyron*, also an old bearing, is the lower half of a quarter divided diagonally. It is a Spanish ordinary, and said to come from "gyron," a gusset. It is seldom borne singly, and usually is gyronny, when the shield is divided per pale, per fess, per bend dexter, and per bend sinister into eight sections. If more, the number must be specified. In the earliest examples the divisions are twelve.

Bassingbourne: gyronny of twelve, or and azure.
 Campbell: gyronny, or and sable (fig. 70).

Fig. 68. Fig. 69. Fig. 70. Fig. 71.

The *Flasque*, or *flaunch*, is the segment of a circle taken out of the two sides or flanks of the shield, the margin of which forms the chord. They are always used in pairs, one on each side. This bearing is not of great antiquity.

The *Voider*, the diminutive of the flasque, has a flatter curve. The voider in defensive armour was a gusset-piece either of plate or of mail, used to cover a void or unprotected space at the elbow or knee joints.

Frero: gules, two pards' faces between as many flasques or (fig. 71), alluded to in *Whitstreak's* by Mr Hookham Frero—

"Two leopards' faces were the arms he bore."

When the bearer was asked to give some verses descriptive of his arms to be placed at the head of a history of the family, his answer was —

"The flanches, on our field of gules,
 Denote, by known heraldic rules,
 A race contented and obscure,
 In mediocrity secure,
 By sober parsimony thriving,
 For their retired existence striving,
 By well-judged purchases and matches,
 Far from ambition and debauches,
 Such was the life our fathers led;
 Their homely lesson, deep inbred
 In our whole moral composition,
 Confines us to a like condition."

The lozenge, the mascle, and the rustre are all derived from the fret or fretty, and do not appear originally to have been used singly.

The *Lozenge* is a square, set up diagonally like the diamond in playing cards. It is seldom used alone, and when the shield is covered with it, it is called lozengey.

Fitzwilliam: lozengey, argent and gules (fig. 72).
 De Burgh: gules, seven lozenges vair conjoined 3,3,1.

The *Mascle*, or rather *maseuly*, for originally it was so used, is said to represent a net.

Rokele of Sniffolk: maseuly, gules and ermine.
 Poges of Stoke-Poges: maseuly, argent and gules.
 De Quincy, earl of Winchester: "gules, six mascles d'or, voydés du champ;" and afterwards, gules, seven mascles or, conjoined 3,3,1 (fig. 74).

The *Rustre* is of later introduction, and is not a common bearing. It is a lozenge pierced in its centre by a round hole.

Custance: or, a rustro sable (fig. 73).

Fig. 72. Fig. 73. Fig. 74.

The *Fusil* is an elongated lozenge, from the French fuseau, a spindle, and is supposed to represent a distaff charged with yarn. A very early example of its use is

Montacute: "d'argent avec un fess engraldé de gules d. trois pièces," which speedily became "argent, three fusils conjoined in fess gules" (fig. 75).
 William of Waynflete and Wilson-Patten: fusilly, ermine and sable, a canton or (fig. 76).

It has been suggested that the Percys derived their fusils from their lordship of Spindleton.

Trefusis of Trefusis: argent, a chevron between three spindles sable.

Fig. 75. Fig. 76. Fig. 77. Fig. 78.

The *Roundel*, if of metal, is a simple disk; if of colour, it is convex, half a globe. It is seldom borne singly, and is named specially from its colour.

- | | |
|--|---|
| <ul style="list-style-type: none"> II Or, a Bezant. „ Argent, a Plate. „ Azure, a Hurt. „ Gules, a Torteau. „ Sable, a Pellet, Gunstone, or Ogress. | <ul style="list-style-type: none"> Vert, a Pompey. „ Tenny, an Orange. „ Sanguine, a Guve. „ Pimpure, a Golpe. |
|--|---|

The last four are almost unknown in English heraldry. Akin to these is the *fountain*, a disk barred wavy, argent and azure, to represent water. Although bezants, plates, hurts, and tor-teaux are given in early rolls of arms, their names do not always carry their colours. They are blazoned as roundels d'or, pelottes d'argent, tor-teaux de gules. The tor-teau is sometimes called a séruse. The pellet often stands for the roundel, and the bezant is called a talent, from a coin of that name current with the bezant in the East.

Alan La Zouch: Gules, bezanty. This was afterwards reduced to ten bezants, 4,3,2,1, with a quarter and sometimes a canton of Britanny, that is, "ermine" (fig. 77).

Camoys: or, on a chief gules three plates (fig. 78).
 Wellesley: gules, a cross argent between twenty plates, 5,5,5,5.
 Baskerville of Old Withington: argent, a chevron between three hurts (fig. 79).
 Hurting: argent, ten hurts, 4,3,2,1.
 Courtenay: or, three tor-teaux (fig. 82).
 Babington: argent, ten tor-teaux, 4,3,2,1, a label azure (fig. 9).
 Filkyn: sable, on a cross between twelve billets argent three golpes.
 Greville: sable, on a cross engrailed or five pellets.
 Bridgeman: argent, ten ogresses, on a chief a lion rampant of the second.
 Stourton of Stourhead: sable, a bead or between three fountains (fig. 81).

Fig. 79. Fig. 80. Fig. 81.

In early lists the annulet is blazoned as a false roundel; thus Vipout is said to bear gules, six falso roundels or.

Guttes or drops are represented pear-shaped with a tail like a Rupert's drop, or the tears or funeral draperies. They are not found in the earliest coats. They, like roundels, are named from their colour, thus: or—gutté d'or; gules—gutté de sang; argent—gutté d'eau; sable—gutté de poix; azure—gutté de larmes; vert—gutté d'huile.

Malory: argent, a cross sable, gutté d'or.
 Winterbottom: azure, gutté d'eau.
 Kington: argent, gutté de larmes; on a chief azure three barons' coronets or (fig. 80).
 Fitz of Fitzford: argent, gutté de sang, a cross of the same.
 Chichester city: argent, gutté de poix, on a chief indented gules a lion of England.
 Marshal: argent, on a fess gules three drops ermine.

The *Billet* or *delve* is a small parallelogram usually borne in numbers and set up on one end.

Condray: gules, billety or.
 Delves: argent, a chevron gules, fretty or, between three delves sable (fig. 82).

Somewhat akin to these subordinaries is a division of the field known as *chequy*, where the field is divided into small squares like a chess-board. Their number is not specified, but usually is made up of seven squares in a line, and in depth according to the length of the shield. Hugh, earl of Vermandois, is said to have borne *chequy*, or and azure, and as his daughter married Warren, it is possible that the earls of Surrey thence derived their well-known coat.

Warren: *chequy*, or and azure (fig. 83).
Tateshal: *chequy*, or and gules, a chief ermine.

Fig. 82.

Fig. 83.

Fig. 84.

Chequy was not confined to the field, but was also applied to the charges upon it.

Stuart: or, a fess *chequy*, argent and azure.

Where there is but one row of squares, the bearing is called *gobony* or *compony*, if of two rows, *counter-compony*.

Gray: Barry of six, argent and azure, a bend *compony* of the first and gules (fig. 84).

Fitz Roy: gules, a border quarterly, ermine and counter-compony, or and azure.

Common Charges.

Next to the purely heraldic figures connected with the shield and their diminutives and subordinaries, come those imported into heraldry as charges from all quarters, including an immense variety of objects, natural and artificial, beasts, birds, fishes, reptiles and insects, flowers, and the fruits of the field, chimæras, astronomical and celestial figures, man and his parts, arms and armour, implements of war and the chase, ships, articles of dress, and a miscellaneous budget far too heavy to enumerate.

The rules for the placing of these charges are simple. If single, they stand in the centre of the shield; if two, in pale, or one over the other; if three, 2 and 1; if the number is longer the order must be specified (see fig. 85). The French carry the unexpressed understanding much further. With them, four pieces are placed 2 and 2; five pieces, in saltire; six are 3,2,1; seven are 3,3,1; eight are in orle; and nine are 3,3,3.

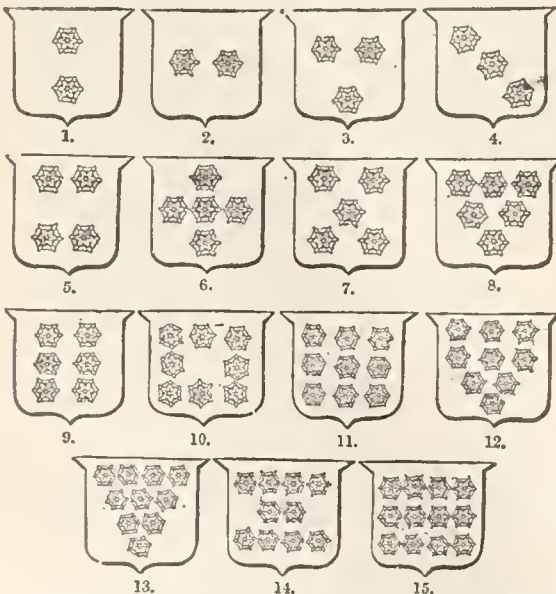

FIG. 85.—Different arrangements of charges upon a shield:—(1) 2 roses; (2) 2 roses in fess; (3) 3 roses; (4) 3 roses in bend; (5) 4 roses, 2 and 2; (6) 5 roses in cross; (7) 5 roses in saltire; (8) 6 roses, 3,2,1; (9) 6 roses, 2,2,2; (10) 8 roses in orle; (11) 9 roses, 3,3,3; (12) 9 roses, 3,3,2,1; (13) 10 roses, 4,3,2,1; (14) 10 roses, 4,2,4; (15) 12 roses, 4,4,4.

ANIMALS.

The following rules are applicable to the blazoning of animals. Generally, unless otherwise specified, they are shown in profile,

looking towards the dexter side; when to the sinister, the word counter is prefixed, "a lion counter-passant." Animals back to back are "addorsed"; face to face, "confrontée"; facing the spectator, "gardant," or "affrontée"; looking back, "regardant"; when rising out of the edge of an ordinary, "issuant"; when out of the middle of it, "naissant." When the claws, horns, tongues, hoofs, or mane are shown of a special colour, the animal is "armed," "corned," "langued" or "lampassé," "ungued," or "cined." Sometimes he is crowned royally or ducally, sometimes "collared," "gorged," or "accollée." When wounded he is "vulned."

When of its natural colour an animal is "proper," but it may be of any metal, colour, or fur, and divided by any partition lines. When a head or member is torn off it is "erased." When cut off "couped." When men are clothed, they are "habited"; when nude, they are "salvage."

QUADRUPEDS.—Of these the *Lion* is by far the most popular, nor is his popularity confined to England. He appears not only in the British arms, but in those of Spain, Holland, Denmark, Bohemia, and Saxony, and many lesser states. Of Edward II.'s 918 bannerets, 225 bear lions in some form or other. The favourite attitude is rampant, but he may be passant, saliant, statant, sejant, couchant, or dormant. About thirty varieties of attitude are enumerated by writers; but most are rarely if ever used, and indeed it is seldom the lion is other than rampant or passant. Sometimes he is borne "demi," especially as a crest. His paws or jambs are also borne, and his tail. In one or two well-known instances on the Continent he is "déhaché," that is, his head and paws and the tuft of his tail are cut off. When a member is borne upright, it is "erected." As a set off to this dismemberment, in early rolls the lion is sometimes represented as two-tailed, or "queue fourchée," and there are examples of bicorporate and triecorporate lions, though not many. When above three lions are shown, they become lioncels or lions' whelps, unless otherwise specified.

It has been shown that as early as 1127 Henry I. used the lion as an ornament upon the shield he gave to his son-in-law, who bore those animals upon his brodekins, as did the early French kings the fleur-de-lys. Mr Planché has investigated this early use of the lion by Henry with great acuteness. A prophecy of Merlin, held to apply to that king, designated him as the Lion of Justice; his favourite residence and death-place was in the forest of Leon or Lyons in Normandy; his wife Adeliza was a daughter of Godfrey, duke of Louvain or Löwen, a name which certainly gave rise to the lion as the arms of that family.

William, earl of Gloucester, Henry's grandson, sealed with a lion. Richard de Redvers, earl of Devon, who married a granddaughter of Henry, also bore a lion, as did Ranulph, earl of Chester, who married another grandchild. William d'Albini who married Henry's widow, used the same animal. All this occurred at a period when armorial bearings were by no means an established institution, and when every great noble was taking it up, and quite open to assume a bearing. On the whole, therefore, it seems probable that to Henry I. was due the introduction of the lion into English heraldry. It has been seen that under Richard and John the lions became the settled arms of England, and this will account for the general adoption of the royal beast in English coats of arms. In heraldry a "lion passant gardant or" is always blazoned as "a lion of England."

The identity of the lion of England with the leopard has been the subject of much controversy, and when Napoleon talked of driving the leopards into the sea he evidently used the word in disparagement of our national bearing. The early heralds, who probably were not zoologists, seemed to have confounded the lion with the leopard, and to have used the names according to the attitude of the animal. When rampant he was a lion, when in any other attitude, as passant, he was leo-pardé or a lion-as-a-leopard, but never drawn spotted like a real leopard. As the lion came more generally into use, and was borne in various attitudes, the allusion to the leopard was gradually dropped, though as late as the reign of Edward III. and Richard II. the royal crest was described as a leopard, and Henry V. had a Leopard herald. Among the greater barons of the 13th and 14th century, the lion was borne by the earls of Arundel, Cornwall, Devon, Hereford, Leicester, Lincoln, the Earl Marshal and the earl of Salisbury, as well as by scores of the lesser barons or knights. Sir Tristram, the knight of lionesse, bore a lion when

"Mordant with his might,
With a lance un-light,
He smote him in the lion."

Fig. 86.

Fig. 87.

Fig. 88.

Fig. 89.

Lewis of Llanishan and Cromwell their cadet bore and bear sable, a lion rampant argent, a bearing still used by their cadets, the Lewises of Peany'sylvania, who migrated above two centuries ago (fig. 89).

Mathew of Castell-y-Mynac: argent, a lion rampant rezardant sable (fig. 87).
 Everingham: gules, a lion rampant vair, crowned or.
 Haverling: argent, a lion rampant queue fourche gules, gorged azure (fig. 88).
 Capel: gules, a lion rampant between three cross crosslets, fitchy, or. In allusion to which Lord Capel is described at the siege of Colchester:—

"There lion-like undaunted Capel stood,
 Beset with crosses in a field of blood."

Sir Simon de Felbrigge, K.G.: or, a lion salient gules (fig. 89).
 Fitz Payne: gules, three lions passant in pale argent, debraised by a bendlet azure (fig. 90).

Fig. 90.

Fig. 91.

Fig. 92.

The lion statant is more usually seen on a crest, and is that of Percy and Talbot.

Tynto of Cefa Mably: gules, a lion couchant between six cross crosslets, argent, 3 and 3.

Aylworth of Essex: gules, a lion dormant or.
 Longspee, earl of Salisbury: azure, six lions rampant or, 3, 2, 1 (fig. 91).
 Edmond, earl of Lancaster: a tripartite lion issuing from three parts of the escautcheon, united at the head, gardant in the less point, or, armed and langued azure (fig. 92).

A Scottish seal of Chalmers, 1449, bears a demi-lion issuant from a fess, in base a fleur-de-lys.

Starkham: azure, on a chief or a demi-lion rampant issuant gules (fig. 93).
 Sir Henry Esme, K.G.: or, out of the middle of a fess a lion rampant issuant gules, armed azure (fig. 94).

Wyndham: argent, a chevron between three lions' heads erased or (fig. 95).
 Newdigate: gules, three lions' jambs erased argent (fig. 96).
 Pinchbeck: sable, three lions' tails erased erect argent (fig. 97).

Fig. 93.

Fig. 94.

Fig. 95.

Fig. 96.

The *Leopard*, that is, the real spotted animal, is seen now and then in coats of arms, but is of much later introduction than the lion, which is often called by that name. Thus Sir Reginald de Dunstauville is blazoned as bearing "gules, two leopards passant debruised of a bâton;" these most certainly were lions. A coat of Astley was however, gules, a leopard rampant argent, in that case a real leopard. He is often called a pard.

Cautelupo: azure, three pards' heads jessant fleurs-de-lys or (fig. 98).
 Wentworth: sable, a chevron between three pards' faces or.
 Mubard of Ipsley, who held under Cautelupo: sable, three pards' heads jessant fleurs-de-lys argent.

The heraldic *Tiger* is neither a common nor an early bearing. To the body of the wolf he adds the tail of a lion, and he is studded with tufts of hair.

The supporters of Hastings, earls of Huntingdon, are two man-tigers affrontés.
 Lone of Ellow bears azure, a tiger passant or.
 Kunloke of Wingerworth: azure, a fess between three heraldic tigers' heads erased or.

The *Wolf*, when salient, is said to be "ravissant."
 Lovett of Astwell: gules, three wolves passant sable, in pale.

The wolf, the boar, the hart, and the hare were the four heraldic beasts of venery. Dame Juliana Berners says—

"Four maner bestys of venery there are:
 The first of them is the hert, the second the hare,
 The boar is one of them, the wolf, and not one mee."

Fig. 97.

Fig. 98.

Fig. 99.

Fig. 100.

The *Boar* is the only beast besides the lion borne in the roll of Henry III., where Adam de Swyneburac bears "de goules, a trois testes de sanglier d'argent" (fig. 99), a bearing which, however, the family have long laid aside for "per fess gules and argent, two cinquefoils counterchanged," a coat derived from Umfraville. The hare or teste de sanglier is a common crest. The "glory of the tusky boar" is in his tusks, "dente timetur aper." He is also borne whole.

Gilpin: or, a boar sable.
 The boar was the cognizance of Richard III., with a thorn bush
 "The bristly boar
 In infant goro
 Wellows beneath the thorny shado."
 In the crest of most of the clan Campbell.

The *Bear* is also a beast of heraldry.

Beresford: argent, a bear rampant sable, muzzled, collared, and chained or.
 Fitz Urso: or, a bear passant sable.

The *Fox*.

Williams: argent, two foxes saliant counter-saliant in saltire, gules, the dexter surmounting the sinister (fig. 100).

The *Cat-a-Mountain*, musion, or wild cat, was long preserved in Rockingham forest, the country of Catesby, the first of the well-known trio—

"The cat, the rat, and Lovel our dog."

Catesby, however, bore argent, two lions passant gardant sable, crowned or.
 Keate: argent, three mountain cats passant in pale sable.

The musion was the emblem of Burgundy and the arms of an imprisoned cat were fabled to have been granted by Childebert to a knight who made prisoner Gundemar of Burgundy.

In the following dialogue from Ferné's *Glory of Generosité* the reader will recognize an amusing passage in Quentin Durward.

"Paradis, the herald.—Therefore, I pray you, begin and tell your soverelgn what coat armour this knight beareth?"

"Torquatus, a knight.—Methinks he beareth sable, a musion passant gardant or, oppressed with a fret gules of eight parts, nayles argent (fig. 101)."

"Columel, a ploughman.—Jezu, Zif! call you this arms? now by my vaye, 'chad thought arms should not have been of such trifling things. Why, this is even the cat in the milk-house window. Full ill will her dayr! thrive gifc she put zatche a vermin beast in trust to keep it."

The *Dog*.—The mastiff or talbot supports the shield of the earls of Shrewsbury. "The talbot ever true and faithful to the crown." In the fine brass of Sir Brian Stapleton at Ingham, 1432, the knight rests his foot upon a dog whose collar is marked "Jakke."

Barton of Falde: azure, a fess between three talbots' heads erased or.
 Mauleverer of Allerton Mauleverer: gules, three greyhounds or levriers courant in pale argent.

The alaud or hunting dog was in great request. Those of Henry VIII. bore his arms and badges on their collars. Fienes, Lord Daere, used it as a supporter.

The *Stag* and *Hart* were old, though not of the earliest bearings. The stag appears in the roll of Edward II. When in motion he is trippant; when lying down he is lodged. His antlers are his "attires;" a pair of attires attached to a fragment of the skull bone forms "a massacre." The head is usually borne full-faced, when it is said to be embossed or cabaged.

Green of Green's Norton: azure, three bucks trippant or.
 Bullstrode of Bullstrode: sable, a stag's head cabaged argent, attired or, and between the attires a cross pale fitchy of the third, transixed through the nostrils by an arrow of the last, barbed and feathered of the second. This is called a stag of St Hubert (fig. 102).

The kingdom of Wurtemberg: or, three attires of a stag barwise in pale sable.
 Coeks: sable, a chevron between three massacres argent.
 Roper: per fess, azure and or, a pale and three rockucks' heads counterchanged.
 John Tis who, temp. Edward II., was son and heir of Alicia de Hentley, bore "a hart's head cabaged."

Fig. 101.

Fig. 102.

Fig. 103.

The stag's head was the emblem and armorial bearing of the M'Kenzie, whose chief, the lord of Kintail, was called by the Highlanders "Caberfaigh"—

"Proud chief of Kintail,
 Let the stag in thy standard bound wild in the gale."

The heraldic *Antelope*, or *agacella*, somewhat resembles a tiger, but has horns and hoofs. Brooke, Lord Cobham, had for a dexter supporter an agacella, horned, tusked, and armed or.

The *Elephant*.

Elphinston: gules, an elephant passant argent, tusked or.
 Saunders of Welford: per chevron, sable and argent, three elephants' heads erased counterchanged.

The *Bull*, or *buffler*, in his wild state was a formidable animal, and is used heraldically, though more frequently as a crest, supporter, or cognizance, than in arms—

"Mightiest of all the beasts of chase
 That roamed in woody Caledon."

Front de Beuf, a real Norman name, probably bore no arms, though Scott appropriately gives him the bull's head. The head cabaged was a Welsh bearing; and when the horns and hoofs are noticed, he is said to be armed or corned and ungued. The bull's head is the crest of Hastings and Nevill, and the pied bull a well-known cognizance.

Skeffington: argent, three bulls' heads erased sable, armed or (fig. 103).

The *Calv*.

Le Vele of Tortworth and St Fagans in Glamorganshire: argent, on a bend sable three calves or.
 Calverley: argent, on a fess gules three calves or.

The *Horse*, the support of the equestrian order, does not appear in early coats of arms, although the winged horse was a cognizance

of the order of the Temple. A grey horse is a liard, a bay a bayard. When in the field he is free, when in harness barded and caparisoned.

Trévelyan of Nettlecombe, whose ancestor is supposed, in Cornwall, to have come out of the sea at the Land's End ready mounted, incongruously enough, upon a land horse, bears gules, a demi land horse issuant from the water, all proper.

Horsey of Melcombe-Horsey: azure, three horses' heads coupéd, bitted, and reined or.

The *Ass*, probably the wild ass endued with sublimity in the book of Job, found a place on the shield of the old Cheshire family of Hockenhull, argent, an ass's head erased sable.

The *Ram*.—Recently a valuable silver dish was fished up from Whittlesea Mere, having rams' heads at each end, evidently once the property of the Abbey.

Ramsay Abbey, "Ramsay the rich," bore or, on a bend azure three rams' heads coupéd argent, armed of the field.

The *Sheep* is occasionally seen, but the *Lamb* from its religious association was in general use. The Pascal Lamb was one of the cognizances of the Templars, and is adopted with equal propriety by the gentlemen of the long robe. As the "Lamb and Flag" it is known extensively in South Wales. Piece of Park and other descendants of Jestyn ap Gwrgan bore it as a crest.

Lambton of Lambton: sable, a fess between three lambs trippant argent.

The fleece of the sheep gave name to the great Burgundian order, and the toison d'or was its jewel. It probably refers to the pastoral wealth of Burgundy, but is said to have been founded by Philip the Good, in allusion, not to the bad faith of Jason, but to the prowess of Gideon.

The *Goat*.—William de Caprville bore a goat "exsiliens." Thorwold of Marston: sable, three goats saliant argent.

The *Coney*.

Coningsby of Hampton Court: gules, three coney argent.

The *Otter*.—L'outre was used as a supporter by Luttrell of Dunster.

The *Squirrel*.

Nutshaw: argent, a squirrel sejant nibbling a nut, all proper, from a batchment in Claybrook Church.

The *Hedgehog*, herison, ericius.—In the church of Gamelston, Notts, is a fine effigy in chain mail of the end of the 13th century, of one of the family of Heriz, and on the shield are three hedgehogs. They bore azure, three hedgehogs or. The hedgehog is also borne by the Maxwells for the lordship of Herries.

The *Mole*.

Mitford of Mitford: argent, a fess sable between three moles proper.

The *Ermine*, the fur of which is borne widely, is scarcely known in heraldry as an animal. The reader will, however, remember the three ermines in the windows of Waverley House.

BIRDS.—The bird of heraldry before all others is the *Eagle*, the symbol of the fourth evangelist. Its earliest and chief popularity was in Germany, where it was adopted by the empire and by many of the principal sovereign princes.

It appears but twice in the roll of Henry III., but after his brother Richard, earl of Cornwall, became king of the Romans, he adopted the eagle, which on that account was to be seen in all the armorial glass of the midland churches, and was widely copied in private coats of arms. His son Edmund, while bearing "Cornwall" for his arms, suspended his shield from the beak, and placed it on the breast of an eagle in reference to his father's rank. In the roll of Edward II. there are forty-three examples of eagles.

The nobles of the old Holy Roman empire place their shields upon the breast of an eagle, as may be seen in England in the insignia of the duke of Marlborough as a prince, and of the earl of Denbigh and Lord Arundel of Wardour as counts, of that empire.

The imperial eagle is always represented with two heads, the origin of which is obscure. The emperor Frederick II. on his contemporary shield in Westminster Abbey has a single-headed eagle. The second head is supposed to have been produced by the dimidiation of two coats, each an eagle, but this is scarcely probable. The eagle of the house of Brandenburg has but one head. Some of the North Wales gentry, headed by Sir Watkin Williams Wynn, place their shields upon the breast of an eagle, single-headed, and the practice is not unknown in Scotland. The seal of the widow of one of the Warwickshire Harpurs in the time of Edward II. gives an eagle, and in his two claws shields of her husband's arms and her own.

Besides the eagles of Austria, Brandenburg, Russia, imperial France, and the United States, the bird was the emblem of Este, Bohemia, and Moravia, of many of the German, Italian, and French nobles, and of many very ancient English and Scottish names, as Monthermer, Bedingfield, Biddulph, Glyn, Weston, in England, and Ramsay, Maxwell, and Carnegie, in Scotland. The great financiers Rothschild use an eagle for their arms.

The eagle is always shown "displayed," that is, upright, with his breast to the front, and his legs, tail, and wings expanded,—what is commonly known as a spread eagle.

When the beaks and talons of birds of prey are specified, they are said to be beaked and armed. In the roll of Henry III., Sir

Drn de Barenton bore sable, three eagles or, and his descendants in the reign of Edward II. had increased the number to six and gave them argent. Piers Gaveston bore six eagles upon his shield and horse furniture.

Peter, earl of Richmond and Savoy, who built the Savoy Palace in 1250, and was uncle of Eleanor, queen of Henry III., on the shield of his monumetal effigy at Aqua Bella bears an eagle for Savoy. The cross, the later arms of that house, appears on theommel of his sword. Long before this, about 1142, when Mathien de Montmorenci married Adela of Savoy, he added four alerions or eaglets to his arms, probably in compliment to his wife, who bore an eagle displayed; and certainly in 1206 the acknowledged arms of the house of Savoy were an eagle.

Parts of birds, especially of eagles, are borne, as the head, wings, legs, and feathers. When feathers are used, and the quill is of a special colour, they are said to be quilled. When a bird is leaving the ground it is "rising," when on the wing it is "au vol," when the wings are down it is "closed," when open "disclosed."

Bedingfield of Oxburgh: ermine, an eagle displayed Barry argent and gules (fig. 104).

Glymne of Hawarden: argent, a two-headed eagle sable (fig. 105).

Calceuth of Calceuth: argent, an eagle disclosed, preycant on a child in a mantle gules, wattle or. This is the crest of Stanley, well known in Lancashire as the bird and bahtling.

Aubrey of Llantrithyd: azure, a chevron between three eagles' heads erased or. Scymour: gules, two eagles' wings conjoined in lure or (fig. 106).

Bray of Siret: argent, a chevron between three eagles' legs erased à la gulse ("caisse," that is, removed at the thigh) sable, armed gules (fig. 107).

Fig. 104.

Fig. 105.

Fig. 106.

Fig. 107.

The *Falcon*, as an accessory to field sports, was much esteemed, and is often borne in heraldry. It is also called a *gerfalcon*, *peregrine falcon*, and *tiercelet*. The falcon is usually borne with the jesses or leather thongs about its legs, sometimes with a hood and bells. It is then jessed, hooded, and belled. When feeding it is "at prey." The lure was a bunch of feathers towards which the bird was taught to return. On the seal of Alice, countess of Eu (1234-42), she bears on her hand a falcon with its jesses pendant. It was the custom to slip over the claws of the young birds a silver ring, which could not afterwards be removed. Two such rings were found at Castle Hedingham, the seat of the De Veres, engraved "Ox-en-forde." One of gold found at Biggleswade bore "Sum regis Anglie," and within the ring "et comitis Herfordie." However well trained, these birds were always liable to prove rifiers, that is, not to return to the lure—

"For though thou night and day take of him hede,
And strew his cage faire and soft as silk,
And give him sugre, hony, bred, and milke,
Yet right anon so that his door is up
He with his feet will spurre down his cup,
And to the wood he will, and wormes," &c.

Falconer of Halkerton bore originally gules, three hawks' lures or. After a marriage with Douglas they bore or, a falcon's head proper, issuant out of a man's heart gules between three stars azure. The English Falconers bore argent, three falcons gules, jessed, belled, and hooded or (fig. 108).

Fig. 108.

Fig. 109.

Fig. 110.

Degge: or, on a bend azure, three falcons rising argent, jessed and belled of the field.

Baker: argent, on a fess gules three falcons' heads erased of the field.

Ridley of Blaydon: gules, a chevron between three gos-hawks argent.

Aldington: sable, three hawks' laies pennéd, stringed, and ringed argent.

The *Swan* was the cognizance of the Bohuns. Humphrey, earl of Hereford, in 1319, bequeathed to his son "un lit entier de vert poudré de cynes blanches." When gorged with a dual coronet having a gold chain attached to it, it is called a *cygnet royal*. The swan was marked or nicked according to the rank of its owner. By a statute of 22 Edward IV. no man having less than five marks

¹ Heralds differ about the blazoning of this coat. The old terms, gules, a pair of wings displayed or, were thought scarcely clear. York described it as gules, two wings conjoined in fess or. Ralph Brooke takes refuge in French with "Denx vols de l'aigle en cœur; but "vol," says Camden, "is a complete pair of wings." Guillim gives "a pair of wings inverted and conjoined." Who shall decide amidst so many wearis of the tabard?

per annum could lawfully keep a "game" of swans. The keeper who looked after them was the "gamester."

Pitfield of Dorset: azure, a bend engrailed between two cygnets' royal. Guest: azure, a chevron or between three swans' heads erased proper.

The Peacock, paon, is more common as a crest than in the shield. He is usually represented with his tail spread, and is then blazoned as a "peacock in his pride," as seen in the crest of Manners.

Pawne: argent, three peacocks in their pride proper. Yeo of Devon bore argent, a chevron sable between three Turkey Cocks, tails expanded, proper.

The Pelican is also more common as a crest than in arms. When in profile she is usually vulning herself, and when full-faced on her nest feeding her young she is "a pelican in her piety."

Came of Nash: gules, a pelican in her piety or (fig. 109). Felham: azure, three pelicans vulning themselves proper.

The Ostrich is also better known as a crest as borne by Digby, or as a supporter by the earls of Buchan. The plume of ostrich feathers, the well-known cognizance of the Black Prince, gave rise to the arms of his natural son, Sir Roger Clarendon, who bore or, on a bend sable three ostriches' feathers argent, passing through as many scrolls of the field. Jervis of Devon: argent, six ostriches' feathers, 3,2,1, sable.

The Stork. Starkle of Huntraydo: argent, a bend between six storks sable. The Heron is one of the few birds found in early coats of arms.

Heron of Chipchase and Ford occurs in the roll of Henry III. One of the family was the husband of her of whom

"Famo
Whispered light tales"

at the court of James IV. They bore gules, three herons argent.

The Cormorant, or liver, appears with a double pen in the arms of Liverpool: argent, a liver sable, billed and legged gules, holding in his bill a bunch of laver vert.

The Shelldrake, also a water-fowl, was introduced into heraldry to suit Sheldon, mayor of London in 1676, who bore sable, a fess between three shelldrakes argent.

The Raven, corbeau, has been the bearing of Corbet from the beginning of armorial bearings.

Corbet of Moreton Corbet: or, a raven sable—
"A raven sat on Corbet's armed crest."
Ravenhill: argent, three mounts vert, on each a raven sable.

The Rook is occasionally borne, and sometimes conjointly with the piece known as the rook in chess.

Rook of Kent: argent, on a chevron engrailed between three rooks sable, as many chess rooks of the first.

The Owl, the bird of Minerva, but seldom condescends to figure in a coat of arms. The learned Sir Henry Savile however bore—

Argent, on a bend sable three owls of the field. Sir Francis Theobald of Barking, Costello's "horum linguarum callentissimus," bore sable, a fess embattled between three owls argent.

The Cock, more usual as a crest, is sometimes borne in arms. When his beak, comb, wattles or gills, and spurs are given, he is beaked, crested, wattled or jewelled, and armed.

Cockalgae: azure three cocks argent, armed, crested, and jewelled proper.

The Popyjay, papagay, or pye, is one of the earliest heraldic birds.

Curzon: argent, on a bend sable three popinjays or, collared gules. Tuwenge or Fitz Marmaduke: argent, a fess gules between three popinjays vert, beaked, legged, and collared of the second.

The Chough is in repute in Cornish heraldry; he is black, with red legs and beak.

Peniston: argent, three Cornish choughs sable, beaked and legged gules. Onslow: argent, a fess between six Cornish choughs proper.

The Shoveller, said to be a Cornish bird, is borne by the family of Herle, who came to Cornwall from West Herle in Northumberland, and probably therefore assumed their arms, argent, a fess gules between three shovellers proper, after their migration. The heiress married Hastings.

Tyrwhit: gules, three tyrwhits or.

The Swallow, or hirondelle, forms the very early coat of the Arundells, of whom William le Brito (1170) says—

"Hirundel velator alite, quæ dat
Hoc agnomen ei."

"More swift than bird light Arundel,
That gives him name and in his shield of arms is blazoned well,
He rides amid the armed troops, and with his spear in rest
(The staff was strong, the point right sharp) runs full upon the breast
Of Sir Guillaume."

Sir Thomas Arundell was by Rudolph II. (1595) created a count of the empire for military service against the Turks. The Arundells of Wardour bear sable, six swallows argent, 3,2,1

FISHES.—The inhabitants of the water do not play a very important part in heraldry, and are scarcely known among the more ancient coats, although a special and interesting volume has been written by Mr Moule on the heraldry of fishes. When borne horizontally they are "naiant;" when vertically, "hauriant,"

though this is not always expressed; when bent they are "embowed" as the dolphin in the crest of Courtenay.

The Pike, or luce, is the oldest example of a fish in heraldry. Lucy of Chaleote, Shakspeare's "Justice Shallow": gules, semée of cross crosslets, three lucies hauriant argent (fig. 110).

The Dolphin, whatever his zoological position may be, is heraldically a fish, as is also the Whale. As the emblem of Dauphiné the dolphin was adopted with the name by the heirs-apparent of the old French monarchy, who quartered with the fleur-de-lis azure a dolphin hauriant or.

Fishacre of Fishacre: gules, a dolphin naiant argent. Kendal of Pelyu: argent, a chevron between three dolphins naiant embowed sable.

Dean Swift says that his cousin Thomas Swift gave for his device a swift or dolphin twisted about an anchor with the motto "Festina lente." This, however, was the device of the printer Aldus.

Whalley of Whalley: argent, three whales' heads erased naiant sable.

The Barbel was also an early bearing, used by the counts of Bar, who bore azure, crusuly fitchy, two barbels erect embowed or, within a border engrailed gules,—a bearing found in the quarterings of many German princes.

The Herring occurs in the roll of Edward II. Heringaud: gules, three herrings hauriant argent.

The manor of Earlton, Norfolk, was held by the service of presenting annually at the exchequer certain herring pies.

Roach.—Peter de Rupibus or Des Roches, bishop of Winchester, bore three roaches.

Conger.—Chief-Justice Gascoyne bore argent, on a pale sable a conger's head erased or.

Trot. Troutbeck: azure, three trouts fretted in triangle argent.

The Chabot, a sort of garnet, was used as a badge by the family of Rohan-Chabot.

The Scallop, or escallop shell, is an old and popular charge, especially in Spain, as the emblem of St James of Compostella, which led to its being the sign of a pilgrim. The seal of the fraternity of St James at Wisby (about 1200) represents St James as a pilgrim with a scallop upon his scrip. Sir Walter Raleigh says—

"Give me my scallop shell of quiet,
My staff of faith to walk upon."

Scales: gules, six escallaps argent, 3,2,1 (fig. 111). Shelley: sable, a fess engrailed between three whelks or.

Fig. 111.

Fig. 112.

Fig. 113.

Fig. 114.

REPTILES, INSECTS, AND MONSTERS.—Reptiles and Insects are charges rarely seen in early coats.

The Serpent is the bearing of the Visconti, dukes of Milan: argent, a serpent gliding in pale azure, crowned or, vorant an infant issuant gules.

The Snake or bisse, anguis.

Sir Wm. de Malbisse: three testes de bysses.

The usual bearing of the name of Vaughan in S. Wales is azure, three boys' heads cupped at the bust argent, wined about the neck with a snake proper.

Dotreaux: argent, three toads (holtraces) erect sable.

The Fly, musca.—Muschamp of Wooler bore argent, a chevron vert between three flies. This bearing is seen on a boss of the cloister at Canterbury, but the musce are represented as butterflies, which loses sight of the allusion.

The Bee.—Both Sir Robert Peel and Sir Richard Aikwright appropriately placed a bee in their arms.

Chimeras.—A chimera is a modification of some existing animal, though often much more than "parce detorta" from its type. Of them the most celebrated is the winged lion of St Mark, the proud emblem of ancient Venice. Technically the bearing is "azure, a winged lion sejant gardant with a glory, or; in his fore paws an open book, thereon 'Pax tibi, Marce, Evangelista meus,' over the dexter page a sword erect,—all proper."

The Dragon, though not very much used in heraldry, is a chimera of ancient date and much employed in early romance. He is thus described—

"There was a dragon great and grymme,
Full of fire and also of venom;
And as a lion then was his fete,
His tayle was long and full unmete;
Between his head and his tayle
Was twenty-two foute withouten foft;
His body was like a wine ton,
He shone full bright against the sun;
His eyes were bright as any glass,
His scales were hard as any brass."

The dragon was a favourite standard with the Welsh princes, and used also by the Anglo-Norman sovereigns. He is drawn with four legs and wings, a long barbed tail usually knotted, and a body protected by scales. In English heraldry he is used chiefly as a crest. In Wales, Rhys Ap Tudor Mawr is said to have borne "argent, a dragon segreant sable."

The *Gryphon* is popular both in romance and heraldry. He is an emblem of vigilance, and inhabited a mountain in Bactria and guarded much gold there. It was in defence of this that he

"Through the wilderness
Pursued the Arimaspians."

He is drawn with the body and tail of a lion, the head of a cock, a pair of wings, and very long sharp claws. When on his hind legs he is segreant.

Morgan of Tredegar: or, a gryphon segreant sable (fig. 112).
Cotton of Welton: azure, a gryphon passant and a chief or.
Evelyn of Landwade: sable, a chevron between three gryphons' heads crested argent.

The gryphon was an early cognizance of Redvers, earl of Devon, and was used statant by some branches of the Montacutes in the time of Henry III.

The *Wyvern* is a two-legged dragon with the body passing off into a long tail barbed at the end and usually borne nowed or knotted.
Drake: argent, a wyvern statant, tail depressed and nowed, gules (fig. 113).

Cockatrice.

Langley: argent, a cockatrice sable, combed gules.

The *Unicorn* or licorne abounds in Scottish heraldry, and was made the sinister supporter of the arms of Great Britain by James I.

"Ceste merveilleuse beste,
Qui une corne a en ta teste
Seneife nostre seigneur,
Ihesu Crist nostre sauveur.
C'est l'unicorne spirituel,
Qui entre la vierge prist ostel."

Harting: argent, a unicorn sejant sable, armed and nagued or.

The Mermaid.

Ellis: argent, a mermaid gules, crined or, in her right hand a comb, in her left a mirror, argent.

The *Martlet*, or merlotte, a small bird without legs, and always represented close. It is one of the oldest and commonest of charges, but seldom if ever borne singly (see Fleetwood, fig. 12).

Fornival of Farnham Royal: argent, a bend between six martlets gules.
Roger de Merley, roll of Henry III.: Barry of ten, argent and gules, on a border azure eight martlets or.

FLOWERS AND FRUITS OF THE EARTH.—Of these the palm was an emblem of victory; the laurel, of triumph; the oak, of strength; the olive, of peace; the cypress, of woe; the vine, of fecundity and joy; the lily, of purity; the daisy, of humility; while the holy

"Trefell, St John's wort, and dill
Hinder witebes of their will."

Fleur-de-lys.—At the head of heraldic flowers, if flower indeed it be, is the *fleur-de-lys* (fig. 60), the *Flos gladioli* of Upton, said to have been brought down by an angel for the arms of France, and which was certainly used by Louis VII. and borne singly and in numbers by Philip Augustus. It may be allied to the lily—

"The lily, lady of the flowery field,
Or fleur-de-luce, her lovely paramour;"

or its original designation may have been "Flenr de Louis." It was not at first popular either in Normandy or in England, occurring but twice in the roll of Henry III., and only twenty times in that of Edward II., nor was it until its assumption by Edward III. that it came into general use in England. The Cantilupes bore three fleurs-de-lys before they added the pards' heads (fig. 98).

Digby of Coleshill: azure, a fleur-de-lys argent.
Portman of Orchard-Portman: or, a fleur-de-lys azure.
Beaumont, to show his claim to descend from the blood-royal of France, bears azure, semée of fleurs-de-lys, a lion rampant or.
Hawkins: argent, on a saltire sable a fleur-de-lys or.
New Collège, Oxford: sable, three lilies slipped argent.

The *Rose* (*Flos florum*) is a very popular charge in English heraldry, though in the roll of Henry III. it occurs but once, and in that of Edward II. only twelve times. Usually the flower is borne alone and full-faced, with five petals, and bars and seeds between them. If a stalk is shown, it is usually "slipped," that is, cut off obliquely.

Boscawen of Boscawen-Rose: ermise, a rose gules, barbed and seeded proper (fig. 114).
Bilson, bishop of Winchester: azure, a rose and pomegranate impaled dimidiated, gules and or, barbed, seeded, stalked, and slipped counterchanged.

The rose is also used in the chaplet, a favourite head ornament, of which a good example may be seen upon the conical helmet of Humphrey de Bohun (1267), in Gloucester cathedral. After the gallant defence of Calais in 1348, in which Edward and the Black Prince served under Sir Walter Manny, the king was so pleased with the valour shown by his prisoner Eustace de Ribeaumont that he took a chaplet from his own head and gave it to Sir Eustace with his liberty, bidding him "wear it for a year for the love of me."
Greystoke: Barry of six, argent and azure, three chaplets gules.

The *Trefoil*, *Quatrefoil*, *Cinquefoil*, and *Sixfoil* are all common charges, usually but not always borne, like the rose, without a stalk.

Harvey of Ickworth: gules, on a bend argent three trefoils slipped vert.
Vincent of Stoke D'Avenon: azure, three quatrefoils argent (fig. 115).
Robert de Bellomont, earl of Leicester (1191-1220), sealed with a cinquefoil bearing on each foil an ermise spot; and Robert de Quincy, the son of one of Earl Robert's sisters, bore "de gules ung quintefoil de hermyne."
Umfravile of Peomarke: gules, a sixfoil or.

Fig. 115.

Fig. 116.

Fig. 117.

The *Thistle*, which gives name to the Scottish order, is also a heraldic bearing in that country.

Leaves, feuilles, are borne by Leveson and Foulis; hazel leaves by Hazelrigg of Nosceley; strawberry leaves, or fraises, by Fraser of Lovat; walnut leaves by Waller; oak leaves by Oakes; by Elmes of Lifford, elm leaves; rye and barley or orge by Rye and Grandorga Bigland bears three ears of big.

Wood and Borough bear trees rooted up or eradicated.
Borough of Chetwynd: gules, the stem and trunk of a tree eradicated and coupé, sprouting in two branches argent.

When Queen Elizabeth visited Worcester the citizens transplanted a pear tree laden with fruit into the market-place, for which attention she added pears to the city arms. Warden abbey, Beds, was famous for a pear that bore its name and constituted its arms—azure, three Warden pears or. The kingdom of Granada bore argent, a pomegranate slipped proper. Sejeaux bore argent, a saltire sable between twelve cherries slipped gules.

The *Garb*, or sheaf, or wheat-sheaf, was a common bearing, especially in Cheshire. Sometimes the garb is banded of a different colour.

Grosvenor: azure, a garb or.
Vernon of Shipbrook: or, on a fess three garbs of the field.

CELESTIAL FIGURES.—The *Sun* was the cognizance of Louis XIV., with the overbearing motto, "Nec pluribus impar." In heraldry this was blazoned as "the sun in his splendour."

Jean de la Hay bore argent, the sun in his splendour gules.
Ralph de la Hay, temp. Henry III., differed this coat by bearing only a ray of the sun, "blanc, ung rey de soleil de goules."

Sir John Aldam, temp. Edward II.: azure, a ray of the sun or. In both examples the ray issues from the dexter chief, and is borne bendwise. It resembles a pile wavy.

Joha de Fontibus, bishop of Ely, 1220-25, bore the sun, moon, and seven stars, 2,1,2,1,2,1.

The *Moon* is always borne as a crescent, and usually with the concavity upwards. If this be to the dexter it is crescent, if to the sinister, decreescent. It is an early and general charge, though seldom borne singly.

Chapman: per chevron argent and gules, a crescent counterchanged.
Weld: azure, a fess nebulé between three crescents ermise.
Baron of co. Lincoln: azure, in chief two moons crescent and decreescent argent, in base an estoile or.
The seal of Sir Lawrence de Berkerolles, 1392, gives a chevron between three crescents (fig. 118).

The *Star*, or estoile, is usually shown with six rays, wavy, and is thus, and by not being pierced, distinguished from the mullet. If there be more rays the number must be given.

Ingilby of Ripley: sable, an estoile argent.
Ooe of the branches of De la Hay bore argent, an estoile of sixteen rays gules.
Sir Francis Drake, in memory of his voyages, bore sable, a fess wavy between the arctic and antarctic pole stars argent.

MAN AND HIS PARTS.—The full human figure is very rarely borne in coats of arms. In Scotland the Dalzells bear sable, a naked man with arms extended, proper; formerly he was borne suspended from a gibbet.

Wood: azure, three salvage men ambulant to fess, proper; in their dexter hands a shield argent charged with a cross gules, in their sinister a clob resting on their shoulders, also proper.

Mr Way mentions an MS. at Melton, in which two knights are represented tilting before a French princess, one of whom bears for a coat three demoiselles caged in a basket.

Canning of Foxcote: argent, three blackmoors' heads coupé sable, capped or, fretty gules.

Fig. 118.

Tremaine of Colcaombe: gules, three dexter arms conjoined at the shoulder, flexed in triangle, or, fisted argent.
 Maynard: argent, three sinister hands conjoined at the wrist gules.
 Foljumbo of Walton bears a man's leg for a crest.
 The Isle of Man: gules, three legs armed in mail proper, garnished and spurred or, conjoined at the thighs and flexed in triangle, a bearing certainly in use as early as the reign of Edward I., and possibly earlier (fig. 116).
 A very extraordinary bearing is that granted to Peter Dodge of Stopworth, Cheshire, by Guyenne King-at-arms, 8th April, 34 Edward I., for services in battle, "porter a son escu d'or et sables, barré de six pièces et unq' pal gules, avec une manille de femme dégoûtante." It is said to be the earliest example of a grant of arms by a herald. Happily for heraldry there are not many such.
 Newton: sable, two shin bones saltire-wise, the sinister surmounted by the dexter, argent.
 Douglas: argent, a man's heart gules, ensigned by a royal crown proper, on a chief azure two stars of the first.

The "*quinque vulnere*" or five wounds of the crucifixion are a common ecclesiastical bearing on architectural shields, and several bishoprics bear figures of saints on their shields, but these are scarcely within the limits of proper heraldry. Thus the arms of the see of Chichester are—

Azur, Presbyter John mitred, seated on a tombstone. In his sinister hand a model, his dexter extended, all or. In his mouth a sword fesswise argent, hilted and pomelled or, the point to the sinister.

MISCELLANEOUS OBJECTS.—*Helmet*.—The helmet completed the knight's equipment. He wore "l'ecu au cou, son heaulme sur la tête, et son glaive au poing," or,

"His helm of latonn bright,
 His saddle was of revelt houc,
 His bridle as the sun shone,
 His spere was of fine cypressa."

Halfday of Hangerford: sable, three helmets argent, garnished or, with a border engrailed of the second. The motto referring to the omitted fourth helmet is exceedingly happy, "Quarta salutis."

Morion, or steel cap.

Murdenel of Dene: argent, a chevron between three morions sable.

Gauntlet.

Ganler of Tregunter: sable, three dexter gauntlets or.

The *Sword* is much used in heraldry; it was the oldest weapon and that most thought of. The soldier in all time was the man of the sword. Damascus, Cologne, Bilbao were in turn famous for the manufacture, as was among smiths Andrea di Ferrara. The swords of great soldiers have been celebrated: Bhowanee of the sword of Sivajee, Excalibur of Arthur, Taillefer of Cœur de Lion—

"Schwafurlama's magie blade
 Was by dwarfs at midnight made."

There was also the weapon by which Roland, with "huge-two-handed sway," cleft the pass of Roncesvalles,

"And to the enormous labour left his name."

The sword of Talbot bore "Sun Talboti pro vincere inimicos suos,"—"Bad Latin," says Fuller, "on it, but good steel in it." King John gave his own sword to the town of Lynn Regis with the inscription, "Ensis hic donum fuit regis Joannis, a suo ipsius latere datum." The sword of heraldry is two-handed.

Kilpee of Eldpee: argent, a sword bendwise sable.

The *Axe* was reckoned a manly weapon—

"King Richard, as I understand,
 Yet he went out of Englonde,
 Let make an axe for the notes,
 Therwith to crush the Saracena bones.

Thereon were twenty pound of steelle."

The Danish battle-axe was famous. Walter de Plumpton held Plumpton by the tenure of a Danish axe that hung up in his hall there.

Hackluyt: gules, three Danish axes or.

Lance.—The arms granted to Shakespeare's father were, or, on a bend sable a lance of the field.

Spear Head.—This is a common bearing among the Welsh of Glamorgan and Brecknock, and used by Jones of Fomnon: sable, a chevron between three spear heads argent, points embued gules. It is quartered by Lewis of Greenmeadow, a cadet of Vau, and by others.

The *Arblast*, or cross-bow, was a most unpopular weapon, as requiring no strength or manliness for its use. Richard I. is generally said to have met his death from a cross-bow; but the earls of Aberdeen, who claimed to represent Bertrand de Gourdon, bear as their crest two arms drawing a long bow. The cross-bow was forbidden by Innocent II. and the emperor Conrad at a council in 1139. Guillaume de Dôle, who wrote before 1200, says of this weapon—

"Par effort de lance et d'escu,
 Conqueront toy esz ennemeles.
 Ja arblastères nu fu mis,
 L'or sa guerre li autoritez."

Nevertheless as early as 1270 the master of the cross-bows was a great officer of the French crown.

Arblastier: ermine, a cross-bow in pale gules.

The *Bow*, though formed of Spanish yew, was essentially an English weapon. It occurs in heraldry, though scarcely so frequently

as might have been expected, and chiefly in allusion to a name. The belt or baldrick, sheaf of arrows, buckler, and sword completed the equipment of an archer—

"Their baudricks set with studs, athwart their shoulders cast,
 To which, under their arms, their sheaves were buckled fast;
 A short sword at their belt, a buckler scarce a span,
 Who struck below the knee, not counted then a man:
 All made of Spanish yew, their bows were wondrous strong;
 They not an arrow drew but was a cloynard long.
 Of archery they had the very perfect craft."

The bow was used by the English in the attack on the isle of Rhé in 1627.

Bows of Streetlam: ermine, three bows palewise strung gules (fig. 117).

The *Arrow*.—Drayton describes

"Their arrows finely paired for timber and for feather,
 With birch and Brazil pierced, to fly in any weather;
 And shot they with the round, the square, or forked pile,
 The loose gave such a twang as might be heard a mile."

The burgesses of Sheffield seal with a sheaf of arrows.

Birdbolt, or bozon.

William de Gresley held a manor "per unum arcum . . . et unam bozonem."

Bozon of Barrowby: argent, three birdbolts gules, feathered or.

The *Pheon*, or broad arrow.

Sydney of Peushurst: or, a pheon azure (fig. 119).

Floyer of Floyer's-Hayes: sable, a chevron between three broad arrows argent.

In heraldry arrows are usually drawn as clothyard shafts. The pheon is always drawn with the head only.

Besides these, and also more or less connected with war and the chase, are the buckle, barnacle, calthrop, castle, fireball, hammer, horse-shoe, hunting horn, mail, pick, spur, stirrup, and some hundreds of miscellaneous objects, travelling so far out of the legitimate charges of heraldry as to include apples and acorns, beehives, and a turnstyle. A very few of the most ancient have been selected.

Walter Agard held Tutbury under Henry II., by a white hunter's horn, and bore for arms, argent, three hunters' horns sable.

The *Chain borne* by the kings of Navarre, the puzzle and delight of French heralds, "gules, a trellis of chains or, in cross and saltire," also blazoned "gules, a carbuncle closed and pomelled or," or by the Spanish heralds—"cadenas d'oro atronesados en campo de sangre."

The *Annulet*, said to be a link of mail.

Grave of Udenhall, derived from Vipont: azure, six annulets or, 3,2,1.

Lowther also derived his arms, or, six annulets sable, 3,2,1, from the same source.

Calthrop—a four-spiked implement, so arranged that when thrown on the ground one spike always stood upright. Calthrops were used to keep off cavalry. Bruce used them at Bannockburn, and among the stores at Dover castle, 16 Edward III., was a barrel containing 2900 calthrappes. Froissart says the English on one occasion supplied their place by sticking their spurs into the ground.

Horseman: or, three calthrops gules (fig. 120).

Fig. 119.

Fig. 120.

Fig. 121.

Fig. 122.

Castle.

Hill: ermine, on a fess sable a castle triple towered arg. nt.

Comb—a singular bearing of high antiquity borne by Ponsouby of Ponsouby and Tunstall of Thirland.

Cups.

Argentiae: argent, three cups gules.

Cushions, oreilliers.

Earls of Moray: argent, three pillows gules.

Maheu de Redman, in the roll of Henry III.: do goules, a trois horelliers or! Possibly these are birds.

Tiara.—The Dukes d'Urbino bore a papal tiara.

Crowns (mural, naval, and others) and *mitres* are not uncommon in arms. The Berkeley crest is a mitre. The *crancelin* or crown of rue was used in 1150 by Saxony. Bernhard of Auhau bore Barry of eight or and sable, a crancelin vert.

Mullet.—This is usually called a spur rowel, but it was in use long before the rowelled spur. Besides being employed as a difference, it is a constituent of numberless coats of arms.

Assheron of Downham: argent, a mallet pierced sable.

But it is generally borne in numbers (see fig. 15).

The *Lymphad* or galley. The bearing of the Lords of the Isles, quartered by the dukes of Argyll for Lorne, is argent, a lymphad, sails furled and oars in action, all sable, flags flying gules (fig. 121).

The *Maunch*, or lady's sleeve—

"A lady's sleeve high-splitted Hastings bore."

The curls of Pembroke bore or, a maunch gules; those of Huntingdon bear argent, a maunch sable. It was borne also by Flanville, Wharton, Maunsel, Convers, and many others. Bayard took a lady's

sleeve and proclaimed it, with a valuable ruby, as a prize to be contended for. Bayard himself won it, and the lady wore it for his sake. Fig. 123 is from the seal of John de Hastings, 1291.

The *Battering-ram* is borne by the Berties, earls of Lindsey, sometime dukes of Ancaster, with the allusive motto, "*Virtus arietis fortior*" (fig. 122).

The *Escarbuncle* was a very early bearing of the Mandevilles. It is a cross of eight rays, set with knobs and the arms ending in fleurs-de-lys. In another form the ends are connected by cross-bars. The escarbuncle of the reign of Henry III. resembles the iron work on doors of that period.

Blount of Bitton: argent, two bars azure, over all an escarbuncle of eight rays gules, fleurettée and pometté or.

Among musical instruments the *Clarion* is borne by Granville, and is seen on tiles at Neath abbey. It resembles a pan-pipe. The *Trumpet* is seen on the fine Trumpington brass near Cambridge.

Williams of Thame: azure, two organ pipes saltierwise, the dexter over the sinister, between four saltires argent.

The *Water Budget* or bucket is an early charge identified with the names of Ros and Rose. Ros, however, got it from the Trusbutts of Belvoir, who possibly bore it as lords of Watre in Holderness. Mr Planché has discovered a drawing of a pair of water budgets in actual use. They were of leather, and carried in pairs on a stick over the shoulder.

Fig. 123.

DEBASED HERALDRY.

Of debased heraldry there is no lack of examples, and a few are ancient. Thomas de Insula, bishop of Ely (1345-61), bore gules, three bezants, on each a crowned king, robed sable, doubled ermine, sustaining a covered cup in his right hand and a sword in his left, both or. No doubt, like the arms of the sees of Chichester and Salisbury, this extraordinary coat was meant to be painted on a banner. Camden granted a great number of coats, mostly of a complex character, and since his time heraldic taste has not improved. Tetlow (granted 1760) bore "on a book erect gules, clasped and leaved or, a silver penny argent, thereon written the Lord's Prayer; at the top of the book a dove proper, in his beak a crowquill pen sable." Other grants show negroes working in a plantation, Chinese porters carrying cinnamon, &c. The grants to Lord Nelson and his gallant captains, and to the elder Herschel, are utterly unheraldic. It can scarcely be wondered at that Lord Chesterfield, correcting the Garter of his day, remarked, "You foolish man, you don't understand your own foolish business."

DIFFERENCES AND MARKS OF CADENCY.

The object of an armorial bearing having been to distinguish one iron-sheathed warrior from another, it was necessary to provide bearings for the members of a family, all entitled to take the paternal coat. This was managed by the introduction of a difference (French, *brisure*), usually some slight but well-marked alteration, sometimes by inverting the tinctures, sometimes by changing an ordinary or a smaller charge, as a bend for a fess, or a crosslet for a martlet. Where an heiress had been married a part of her coat was often introduced. The object was with a sufficient difference to show the connexion with the head of the house. The following examples are from the families of Hastings and Zouch. Females, who wore no armour, did not need distinguishing marks, and bore the coat unbroken.

Sir John Hastings bore (see fig. 123) or, a maunch gules, called "*le de plein armes*."

Sir William Hastings bore the same, with a label of Pembroke.

Sir John Hastings bore the same, with a border of Valence.

Sir Edmund Hastings bore the same, with a label vert.

Sir Nicholas Hastings bore the same, with a label azure.

Sir Miles Hastings bore or, a fess and a chief, three mullets gules.

Sir Philip Hastings bore the same, with a label azure.

Sir Robert Hastings bore ermine on a chief azure, three mullets or.

The label of Pembroke and border of Valence show the match with the heiress of Valence, earl of Pembroke. Sir Miles formed a distinct branch, that of Daylesford, probably before armorial bearings were fixed; his descendants, however, returned to the maunch.

Sir Alan la Zouch bore gules, bezanty.

Sir William la Zouch bore the same, with a quarter ermine.

Sir William la Zouch bore the same, with a label azure.

Sir Oliver la Zouch bore the same, with a chevron ermine.

Sir Amory la Zouch bore the same, with a bend argent.

Sir Thomas la Zouch bore the same, on a quarter argent a mullet sable.

The quarter ermine is to show the descent from the dukes of Brittany.

These and many others of an early date are suitable for their purpose; but, as armorial bearings became less actually useful, alterations of a different character crept in. The label, however, retained its place. It closely resembles the strap with pendants which from the saddle crossed the horse's chest. The earliest example of its use is said to be by Geoffrey, son of Henry II., in 1153, but a more certain case is the seal of Saher de Quincy, though whether there borne as a charge or as a difference is uncertain. At Caerlavrock Maurice de Berkeley bore a blue label "*parceque ces pere vivoit*." In Scotland William Fraser, in 1295, uses a label of three points and on each three roses or mullets, probably meant for "*fraises*" or strawberry leaves. The mullet, crescent, and fleur-de-lys are used as differences about the same time. The label, even then, was most frequently used by the eldest son, but occasionally he used the crescent, and the label was taken by the second son. The royal house generally used the label, but occasionally the border. Edward I., as prince, bore a label of five points azure; Edmund Crouchback his brother, who married a French princess, charged the label with fleurs-de-lys. His second son, Henry, bore England with a bendlet ermine. Thomas and Edward, second and third sons of Edward I., used labels. Edward IV., as prince, bore on his great seal a label of three, and on his counterseal one of five points. John of Eltham, his brother, bore England with a border of France. The Black Prince, who bore France and England quarterly, added a label argent, and Richard, during his father's life, placed a cross of St George on the middle point. Lionel, third son of Edward III., having married the heiress of De Clare and De Burgh, used a label and on each point a canton gules, said to be the original arms of De Clare, and on his seal as earl of Ulster each point bore a cross for De Burgh. The number of points was matter of indifference, though usually confined to three. The label itself was, on the whole, and has continued to be, a mark for all the princes of the royal house.

Setting aside the royal family, a new system of differences came into use, and is touched upon by Upton early in the 15th century, though then but imperfect. He gives the crescent to the eldest son, and to the others the label with three or more points in succession. Dame Berners, in 1486, besides employing the billet, crosslet, and other marks, describes a method of differing by "*gerratting*," that is, powdering the field with billets or other charges, but the good lady's coats are often mere fancies. The first regular appearance of the modern system is on the effigies of seven Beauchamp cadets in St Mary's windows at Warwick. There the label, annulet, crescent, martlet, fleur-de-lys, and mullet indicate the several cadets. The label is placed in chief, the rest on the fess point of each surcoat.

The modern marks now regularly admitted are—(1) the label of three points; (2) the crescent; (3) the mullet; (4) the martlet; (5) the annulet; (6) the fleur-de-lys; (7) the

rose; (8) the cross moline; (9) the octofoil (fig. 124). The elder son of the elder son places a label upon a label, the second a crescent, and so on, so that the ninth son of a ninth son would bear an octofoil upon an octofoil, pointing out the relationship of each member to the parent stock. Practically, however, marks of cadency are but seldom

FIG. 124.—Marks of Cadency.

used. The earls of Harrington indeed, descending from the second son of a second son, place a crescent upon a crescent. Lords Abergavenny and Braybrooke difference their Neville saltire with a rose, as springing from the seventh son of Ralph, earl of Westmoreland. On the other hand Lord Derby, though a cadet, bears his arms unbroken.

Marks of Illegitimacy are very various, and on the earlier coats not to be distinguished from differences. Probably the earliest English example is afforded by Wm. Longspec, natural son of Henry II., who bore six lioncels, no doubt derived from his father, though usually attributed to his wife Ela, heiress of the earldom of Salisbury. His counterseal bears the long sword whence he derived his name. The sons of Richard, brother of Henry III., bore their father's lion of Poitou, inverting the colours, until Sir Geoffrey Cornwall took prisoner the duke of Brittany, when he changed his field to ermine. In the roll of Edward II., Sir John Lovel le Bastard bore Lovel, usually or and gules, with "un label d'azur." Sir Roger Clarendon, son of the Black Prince, has already been mentioned (page 701). John Beaufort, son of John of Gaunt, bore per pale argent, and azure on a bend gules three lions of England, with his father's label. After his semi-legitimation he bore England with a border gobony argent and azure, the Lancaster colours. Arthur, Viscount Lisle, son of Edward IV., placed a bâton over his father's arms. Sometimes the father's coat was altered. Sir John Stanley bore a coat compounded of Stanley and Lathom. Sometimes a bâton sinister was added, sometimes a border. Strictly a natural son does not adopt his father's quarterings, unless such as are habitually borne conjoined, as the royal arms. The descendants of Charles II. bear the whole arms with a bâton sinister or border; those of William IV. the bâton. With the house of Bourbon the bâton marked the cadets, the bâton sinister the bastards. Sir Gilbert Talbot (1569), son of a bastard son of Sir Gilbert Talbot, was allowed Talbot and the usual five quarterings of the family, with a bendlet sinister over the whole, but this is unusual.

RULES OF BLAZON.

To blazon a coat of arms is to describe it in the technical language of heraldry; and, although the works of the fathers of heraldic lore contain much irrelevant matter, and some confusion of arrangement, the rules of blazon, by whomsoever devised or perfected, are remarkable for their precision, brevity, and completeness. Great and successful care has been taken to produce clear and simple order, to avoid repetition, and to preserve a certain uniformity of arrangement through much complexity of detail. The technicalities arise in great measure from the use of terms once well known, and the language, as was to be expected, shows traces of the French and Franco-Norman channels through which the "gentle art" reached England.

First comes the description of the field, its colour, or the arrangement of the colours (if more than one), and the character of the partition lines when parted. Thus the "parma inglorius alba" would be blazoned "he beareth argent." The coat of Waldgrave is per pale argent and gules; that of D'Ebroucis, earl of Gloucester, was "per pale dancetto argent and gules."

Next follow the charges, and first those of most importance and nearest the field, their name, number, and position (if an animal, its attitude), and finally the colour. The principal charge is that which occupies the principal position. Thus Backhouse of Kellet bore party per saltire, azure and or, a saltire ermine; Bigland of Bigland, azure, two ears of bigg or. Where the principal charge is an ordinary placed between smaller charges, it follows the field: Foliot,—or, a fess between two chevrons gules. The same rule holds where the ordinary is charged, as in Braithwaite of High Wray,—gules, on a chevron argent three cross crosslets fitchy sable; or when the two are combined, as Kerr of Cessford,—vert, upon a chevron between three unicorns' heads erased argent, horned and crined or, as many mullets sable. Where the ordinary may be charged, but does not admit of being placed between charges, it is blazoned thus: Russell,—argent, a lion rampant gules, on a chief sable three escallops of the field. If the field be semée of figures (*i.e.*, besprinkled with them in regular order) they follow it: Pierrepoint,—argent, semée of cinquefoils gules, a lion rampant sable. Had the cinquefoils been on the lion instead of on the field the blazon would have run, argent a lion rampant sable, semée of cinquefoils gules.

The arrangement of common charges has already been explained (page 698, fig. 85):—if one, central; if two, per pale; if three, 2 and 1; if more, as must be specified, as in Babington (fig. 9). Such diminutives as are borne in pairs follow their ordinary: Cludde,—argent, a bend between four cotises sable. To avoid repetition, if a tincture occurs twice reference is made to the first: Scott of Abbotsford,—or, two mullets in chief and a crescent in fess, azure, within an orle of the last; and so if the same number of charges occurs twice, the words "as many" are used: Maling of Scarborough,—ermine, on a chevron vert between three hawks' jesses as many roses argent. Upton, who wrote in Latin, is put to strange shifts to express his meaning. He thus blazons the arms of Mortimer (fig. 63):—

"Portavit arma barrata, et caput scuti palatum est et angulatum de azorio et auro, cum quodam scuto simplici de argento." In heraldic French this is, "Il portoit barrée et ung chef palé cunetée d'azur et d'or, et ung escu simple d'argent."

The following, from Menestrier, is the full blazon of the arms of the old kings of France:—

D'asur a trois fleurs-de-lys d'or 2 and 1. Escu timbré d'un casque ouvert d'or placé de front, assorti de ses lambrequins d'or et d'azur, couronné de la couronne imperiale Française, entouré des colliers des ordres du St Esprit et St Michel, soutenu par deux anges vêtus en Levites; la dalmatique des émoix de l'escu tenant chacun un bannière de France; le tout placé sous un grand pavillon d'asur fleur-de-lisé d'or doublé d'ermine; le comble rayonné d'or et couronné de la couronne imperiale Française.

Le dit pavillon attaché à la bannière ou oriflamme du Royaume. Cri du guerre, "Montjoye St Denis." Devise, "Lilia non laborant neque nent," alluding to the operation of the Salic law.

MARSHALLING ARMS.

Marshalling is the disposing or arranging of such coats of arms as have to be included in one shield. Blazoning deals with the particulars of each coat, marshalling with its position as regards other coats. Arms may be arranged per pale or impaled, or the shield may be divided into as many squares as may be required, when it is said to be quartered. The first coat, that of the bearer, may or may not be repeated in the last quarter as may be required to make up an even number of squares, which, though not necessary, is desirable.

For a time armorial bearings were purely personal, and intended to supply a want only felt by the wearer of armour. Hence, at first, females do not seem to have used them, and when a place was found for them on armorial seals, the coat was regarded as that of their father, and therefore not differenced. For a time they seem to have had a separate shield. On one of the seals of Margaret of France, queen of Edward I., his three lions are displayed upon the point of her tunic, and on her right hand is a shield of France, on her left, one with a lion rampant. On the reverse is a shield of England, and around it, outside, a border of France. Margaret Bruce of Skelton married Robert de Ros. Her seal (1280) bears her effigy, somewhat defaced, so that nothing can be distinguished on her dress, but on her right is a shield of Ros, on her left one of Bruce.

A well-known seal, date about 1347, is that of Joan, daughter of Henry count of Bar, by Eleanor daughter of Edward I. by Eleanor of Castile. Joan was widow of Warren, earl of Surrey. Her seal is circular, with nine compartments. In the centre is Warren for her husband; above and below, England for her grandsire; right and left are two barbels for her father. These four are on lozenges. In the four corner compartments are—(1) and (4) a lion for Leon, and (2) and (3) a castle for Castile, for her grandmother. This is a sort of nebulous quartering.

To this succeeded the allotment to the wife of the sinister half of the husband's shield, displayed as though two shields had been divided vertically and united, omitting therefore the adjacent half of each coat. This is called dimidiation, and the shields so joined constitute an impalement. Another seal of Margaret of France illustrates this practice. In it half of England impales half of France.

There is a good example of dimidiation in the tomb of William de Valence at Westminster, where Valence impales Clermont-Nesle, both dimidiated. An early German seal combines half an eagle with half a lion in this way. The arms of the Cinque Ports are remarkable examples of dimidiation. In each, the lions of England are dimidiated with the arms of the special Port. That of Hastings (fig. 125) is party per pale dimidiated, Dexter, gules, three lions passant gardant or; Sinister, azure, three demi-bulks of ships argent. Sometimes one of the coats only was dimidiated. Eleanor (Montendre) was widow of Guy Ferre. Her seal (1348) has a shield of Ferre, a cross moline and over it a bâton, dimidiated, impaling Montendre, a lion within an orle of trefoils. The lion is whole. The seal of Elizabeth, wife of Sir Lawrence Berkerolles (fig. 126),—azure, a chevron or, between three crescents argent, impaling a lion rampant,—is a good example of an impalement without dimidiation (date 1392).

Usually the lady has the sinister side, but in the seal of Marion, wife of Sir William Dalziel (1392) this is reversed, as it is in the impaled shield of John of Gaunt, where his wife, a daughter of Peter of Castile and Leon, has the dexter side. Dimidiation is not applicable to all coats. A canton on the sinister coat would be lost, and a chevron be converted into a bend. The tressure, orle, and border were usually, not always, dimidiated; and although this form of im-

palement has fallen into disuse, these charges are still borne dimidiated, as may be seen with the border and tressure on the tomb of Mary, queen of Scots.

When the lady was the last of her race, various modes were devised for the conservation of her name and arms. Thus on the death (1193) of Robert de Jacy, last of the line of Pontefract, John, constable of Chester, half-brother to Robert by his mother, took the name and arms of Jacy, and was ancestor of the earls of Lincoln of that name. In the same century Isabel, heiress of Earl Warren, married Hamelin Plantagenet, who took the name, and their children bore the arms of Warren; and so with the Mandevilles, earls of Essex.

Sometimes a coat was compounded of the two families. Thus Mr Planché is of opinion that the bend was added to the paternal coat of Bohun, on the marriage with the heiress of Milo, earl of Hereford. Scottish seals show many examples of such composition. Eustacea Colvile, widow of Reginald le Chein, in 1316, bore a cross moline, square pierced, for Colvile, between four cross crosslets fitchy for Chein. About the middle of the 14th century began the practice of placing the arms of females upon a lozenge. As early as 1347 Elizabeth D'Arcy so bears her arms, as in 1356 does Maud Fitz Rayne. The seal of Joan Beaufort, widow of James I., affords the earliest Scottish example.

The first step towards a regular method of preserving heraldically the memory of a family extinct in the male line seems to have been taken in Spain by a process now known as quartering. Eleanor of Castile, queen of Edward I., has upon her tomb a shield divided into four quarters, in the first and fourth of which is Castile, and the second and third Leon. The practice, though not finally regulated, was approved, for on the seal of the "She-wolf of France," queen of Edward II., the shield is quartered (1) England, (2) France, (3) Navarre, (4) Champagne, mixing up confusedly the arms of husband and wife, as they also are upon the shield of Philippa of Hainault, queen of Edward III., who bore quarterly, (1) and (4) England, (2) and (3) Hainault and Holland. A very early instance of regular quartering occurs in the will of Humphrey Bohun, earl of Hereford, dated 11th August 1319, by which he bequeaths a courte-point quartered with the arms of England and Bohun. This is five years before the accession of Edward III., and makes it probable that the quartered coat of William de Foix at Winchester is original.

Under Edward III. quartering came into general use. The king led the way by quartering France and England, and the earl of Pembroke followed, quartering Hastings and Valence. John Hastings, his son, commemorated on his shield his father's match with Ann daughter of Margaret, duchess of Norfolk, a co-heir of Thomas of Brotherton, and this affords an early instance of the precedence often given in quartering to the royal arms. John Hastings bore quarterly of four—(1) and (4) Brotherton (Plantagenet), (2) Hastings, (3) Valence; and, on another example—(1) and (4) Brotherton, (2) and (3) Hastings quartering Valence. This latter arrangement of sub-quartering shows a considerable advance in the system. Henry IV. combined quartering with dimidiation in a shield long preserved in the window of Christ Church, Newgate, which bore France and England quarterly, impaling France with a bend gobony, and Navarre quarterly, dimidiated, for Joan of Navarre. In this case the 1st and 3d quarters were removed, and the sinister bearings thus reduced to what may be better blazoned as party per fess, (1) Navarre, (2) France. The French sometimes quartered diagonally, called "Ecartelé en sautoir." The old kings of Sicily thus divided their shield: party per saltire, (1) and (4) Aragon, (2) and (3) Swabia. This plan never found favour in England, where

Fig. 125.

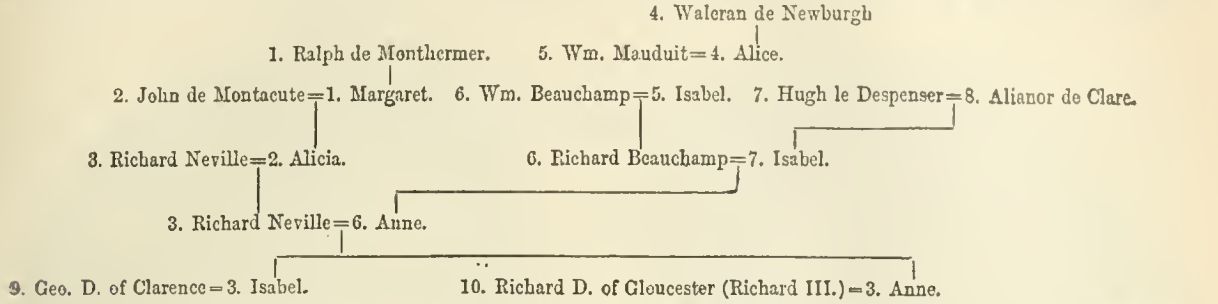

Fig. 126.

a regular system of quartering sprang up, and has continued in use. A quartered shield, though of no special family, is shown by fig. 12.

At first the arms of an heiress were impaled by her husband, but latterly they were placed on a central inescutcheon designated an escutcheon of pretence. The

children divided the shield into four quarters, and placed the paternal coat 1 and 4, the maternal 2 and 3. If a second heiress came in, she was placed in No. 3; if a third, in No. 4; if more, the shield was divided as required. The following pedigree will explain the system. In it all the descents that did not bring in an heiress are omitted.

1. Monthermer : or, an eagle displayed vert.
2. Montacute : argent, three fusils conjoined in fess gules.
3. Neville : gules, a saltire argent.
4. Newburgh : chequy or and azure, a chevron ermine.
5. Mauduit : argent, two bars gules.
6. Beauchamp : gules, a fess between six cross crosslets or.
7. Le Despenser : quarterly, 1 and 4 argent, 2 and 3 gules, a fret or, over all a ribbon sable.
8. De Clare : or, three chevrons gules.
9. Clarence : quarterly France and England, a label of three points argent, each charged with a canton gules.
10. Gloucester : quarterly France and England, a label of three points ermine, on each point a canton argent.

The armorial bearings of each generation will be as follows :—

1. Monthermer alone.
2. Montacute impaling Monthermer.
3. Neville impaling quarterly, 1 and 4 Montacute, 2 and 3 Monthermer.
4. Newburgh alone.
5. Mauduit impaling Newburgh.
6. Beauchamp impaling quarterly, 1 and 4 Mauduit, 2 and 3 Newburgh.
7. Le Despenser impaling De Clare.
8. R. Beauchamp : quarterly of four—1 and 4 Beauchamp, 2 Mauduit, 3 Newburgh ; impaling quarterly of four—1 and 4 Le Despenser, 2 and 3 De Clare.

3. R. Neville : quarterly of four—1 and 4 Neville, 2 Montacute, 3 Monthermer ; impaling quarterly of six—1 and 6 Beauchamp, 2 Mauduit, 3 Newburgh, 4 Le Despenser, 5 De Clare.
9. George, duke of Clarence : France and England quarterly, impaling Isabel Neville quarterly of nine—1 and 9 Neville, 2 Montacute, 3 Monthermer, 4 Beauchamp, 5 Mauduit, 6 Newburgh, 7 Le Despenser, 8 De Clare.

The above, being a well-known and very noble pedigree, has been selected to illustrate the system of quartering, which is explained by the shield (fig. 127), thus emblazoned :—

1, George, duke of Clarence ; 2, Neville, who brings in 3, Montacute ; 4, Monthermer ; 5, Beauchamp, who brings in 6, Mauduit ; 7, Newburgh ; 8, Le Despenser ; 9, De Clare.

Unfortunately the several bearers of these arms were fanciful, and sometimes gave precedence to one and sometimes to another coat, and indeed never used the whole, which would have crowded their shields and caparisons. The four woodcuts, figs. 128-31, will illustrate this.

Fig. 127.

FIG. 128.—Seal of Richard Beauchamp, earl of Warwick.

They represent the great seals of Richard Beauchamp, earl of Warwick, who married Isabel le Despenser, and Richard Neville, earl of Warwick, who married Anne Beauchamp. Beauchamp quarters the arms of his wife, but makes De Clare impalo Le Despenser, while he himself impales Newburgh. The

FIG. 129.—Counterseal of Richard Beauchamp, earl of Warwick.

blazon would thus be quarterly of four grand quarters—1. and IV., Beauchamp impaling Newburgh ; II. and III., De Clare impaling Le Despenser (fig. 128). On the counterseal (fig. 129) the earl bears on his shield Beauchamp and Newburgh quarterly, and on his caparison Beauchamp, Newburgh, De Clare, and Le Despenser also quarterly.

The other is the seal of the king-maker. As lord of Glamorgan he gives precedence to De Clare and Le Despenser, and bears quarterly of four grand quarters—I. and IV. quarterly, De Clare and Le Despenser; II. and III., Montacute and Monthermer; Neville not appearing at all. The crests are those of Beauchamp and Montacute. The remaining supporter is the Neville bull, muzzled, and below are ragged staves for Beauchamp (fig. 130).

The counterseal gives on the shield Neville above with a label, and the swan crest on the helmet. The caparisons are quarterly of four grand quarters: I. quarterly—1, effaced; 2 and 3, Newburgh charged with five pards' heads, jessant fleurs-de-lys for Cantelupe; 4, Beauchamp; II. and III.—1 and 4, De Clare; 2 and 3, Le Despenser; IV.—1 and 4, Beauchamp; 2 and 3, Newburgh (fig. 131).

FIG. 130.—Seal of Richard Neville, earl of Warwick.

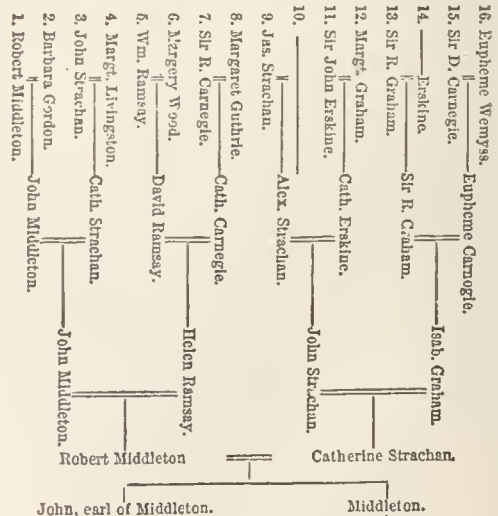

FIG. 131.—Counterseal of Richard Neville, earl of Warwick.

The rules were also departed from where the royal arms were quartered, as by Devereux, Hastings, and Stafford, when it was usual to place them in the first or second quarter out of their genealogical order. Also in certain cases the quarterings of an heiress are not broken up, but borne combined as a sub-quarter, sometimes called a grand quarter. Thus the royal arms always form a special quarter, and probably the arms of Howard, quartering, as they always do, Brotherton, Mowbray, and Warren, would be so treated.

The English mode of quartering is defective, inasmuch as it affords no proof of purity of descent on both sides. A new man whose father married a Talbot or Clinton heiress would combine their ancient quarterings with his new coat, and few would be the wiser. On the Continent and in Scotland the system is far more perfect, and the quarterings include all ancestors and ancestresses of every kind. There a man who can prove the arms of his father and mother has two quarters; of his grandfather and grandmother, four; and so on. The following scheme, supplied from the family records of Mr C. J. Middleton, registrar of the prerogative court, the representative in the male line of a Scottish family, the Middletons of Fettercairn, two of whom were earls of Middleton, will explain this. It gives, or nearly gives, the well-known "seize quartiers," without which, in former days, scarcely any important office was ever to be obtained:—

1	2	3	4
5	6	7	8
9	10	11	12
13	14	15	16

FIG. 132.

The arms are thus marshalled (fig. 132):—

Quarterly of 16:—1, Middleton; 2, Gordon; 3, Strachan; 4, Livingston; 5, Ramsay; 6, Wood; 7, Carnegie; 8, Guthrie; 9, Strachan; 10, —; 11, Erskine; 12, Graham; 13, Graham; 14, Erskine; 15, Carnegie; 16, Wemyss.

When John de Foix, count of Candale, was about to marry Joan, daughter of William de la Pole, duke of Suffolk, by Alice Chaucer, the "probatio nobilitatis" was sought for, though with little success, in England:—

"1. Petitur informatio lineæ De la Pole, et primo quænam fuerit mater Gⁱ. de la Pole; 2^{do}. Quinam fuerint ejusdem pater et mater; 3^{do}. Quænam fuerit uxor Thomæ Chaucer seu mater Aliacæ, &c. . . . Placbit arma gentilitia familiarum Pole, Chauceri, et aliarum, quæ apponuntur in superioribus locumentis, indicare, aut pictura cum debitis coloribus, aut scriptura, per armorum figuras et colores."

This sort of escutcheon at once placed before the eye the heraldic history of the family for four generations.

Bishops, deans, kings-at-arms, and the heads of certain corporations wear their paternal arms impaled by those of their office. No provision is made for the wife.

Single women or widows bear their arms upon a lozenge. Widows and peeresses use their husband's supporters. Peeresses in their own right use their own. But no lady uses crest or motto.

A commoner who marries a peeress in her own right uses two shields. On the dexter are his own arms with those of his wife on a scutcheon of pretence ensigned with her coronet; on the sinister the lady's arms alone on a lozenge with supporters and coronet. If the lady be only a dowager peeress, and not an heiress, there are also two shields. On one the husband impales her arms in the ordinary way; on the other are the lady's arms, &c., as a widow, impaled by those of her first husband, with his supporters and coronet, but no crest, and the arms in a lozenge.

A baronet of England or Ireland bears a sinister hand coupé gules on an inescutcheon or a canton. It is blazoned "argent, a sinister hand, coupé at the wrist and appaumée, gules." Those of Nova Scotia bear argent on a shield of pretence, Scotland ensigned with a crown.

Bacon of Redgrave, the premier baronet, bears gules, on a chief argent two mullets pierced sable (fig. 133).

A knight of an order surrounds his shield, usually a cartouche, with the ribbon and motto of the order. If married he takes a second and sinister shield, and thereon impales his wife's arms, the whole within a plain ribbon.

A widower marrying a second wife divides his shield tierce per pale, and places his own arms in the centre, his first wife's on the dexter, his second's on the sinister side. For a greater number there is no strict rule. A certain Sir Gervase Clifton who survived seven wives, placed himself in the centre of the shield, and his wives around him. The widow of two husbands may divide her lozenge tierce per pale, and place her first husband on the dexter side, her second in the centre, and herself in the sinister place; or she may divide the dexter half on her lozenge per fess, and place the arms of the first husband above, and those of the second below.

APPENDAGES.

These include whatever is borne outside the shield, as the crest, badge, motto, supporters, helmet, coronet, and some other additions. Strictly speaking, armorial bearings are confined to the contents of the shield; and heralds have never regarded the appendages as of the same importance.

The *Crest* was the ornament of the headpiece, and afforded protection against a blow. In early rolls of arms it is not noticed. In early seals when it appears it is rarely heraldic. Richard I. wears a sort of fan-shaped ornament, but has a lion passant gardant on the front of his helmet. Edmund Touchback in 1296 uses distinctly a crest. Of fourteen seals of horsemen in complete armour appended to the barons' letter to the pope in 1301, three only have regular crests, although many have plumes. The three are—Thomas earl of Lancaster and Ralph earl of Gloucester, men of high rank, and Sir John St John, a great military commander. In the 14th century they became general. In 1355 the count of Hainault presented to Edward III. "unam galeam

pretiosam cum apparatu quam idem comes solebat in capite suo gestare." This was the crest of the eagle seen on the count's seal, and which the king regranted at the fords of Annan to Montagu, earl of Salisbury. Edward himself used the lion, which has continued to be the crest of the English sovereigns. Adam de Blencow (1356-7) had a grant of arms and crest of the Grey-stoke beakings from William, lord of Grey-stoke.

Richard Beauchamp, earl of Warwick (died 1439), rests his feet upon the crests of the bear and griffin for Warwick and Montagu. His paternal crest, the swan's head out of a ducal coronet, is placed upon his helmet, beneath his head. The dragon and wyvern were common crests, and the plume of feathers is still used by Scrope and Courtenay. Ralph, Lord Neville of Raby, used the bull's head in 1353; Hastings, a bull's head in 1347. Crests were, like arms, allusive. Grey of Wilton used a "gray" or badger; Lord Welles, a bucket and chain; Botreaux, a buttress. The crest was sometimes placed on a ducal coronet, sometimes rises out of a wreath or torse of the colours of the arms. The coronet below the crest is not a mark of rank. In Carlisle cathedral is the crest of Davidson, a bird rising out of an earl's coronet. This, however, is rare; the coronet so used is generally ducal. Crests were granted and bequeathed. In Germany it is usual to bear the crests of the "seize quartiers" or some of them. This of course is inconsistent with the actual use of the crest in war. At first crests were confined to persons of rank, but they have long been included in every grant of arms. In England two or more can only legitimately be borne when the bearer has from the crown a grant of name and arms in addition to his own, as Chetwynd-Talbot, Fitz-Alan-Howard.

With the crest is usually combined some flowing drapery known as the "panache," "mantling," or *lambrequin*. This seems to have served to protect the helmet from heat and dust, and was also ornamental. It is represented in great perfection on tombs of the 15th and 16th centuries, commonly of some brilliant colour with a lining and tassels. The tilting helmet which supports the head of the effigy of Humphrey de Bohun (died 1267), at Gloucester, is accompanied by a grand early specimen of the *lambrequin*.

The *Badge* or *Cognizance* was not worn on the helmet, but displayed upon the persons of the retainers of great barons, and sometimes used to ornament the shield or seal. At the celebrated judicial combat at Coventry before Richard II. in 1398, Henry of Lancaster appeared with his housings of blue and green embroidered with swans and antelopes, his badges; and Mowbray had housings of crimson velvet, embroidered with silver lions and mulberry trees, his badges. The bear was the Beauchamp badge, derived possibly from Urso D'Abitot. They also used the ragged staff and the combination of the two.

The seal of Richard III., 1484, as lord of Glamorgan, exhibits the bear as a supporter, and the counterscal repeats it as a badge (figs. 134, 135). This seal well illustrates various heraldic points. Its blazon is per pale, baron and femme; baron, France modern and England quarterly, over all a label of three points; femme, per fess, Beauchamp, and chequy, on a chevron five pards' heads jessant fleurs-de-lys, for Newburgh combined with Cantilupe. The same arms are repeated on the shields and caparisons of the counterscal. Richard married Anne Neville, but the Neville saltire does not appear, only the arms of Beauchamp and Newburgh, both of whom were earls of Warwick.

"The rampant bear chained to the ragged staff" was inherited by the Nevilles and Dudleys, and granted about 1759 to the Grevilles as the owners of Warwick castle. Pelham used a buckle, Percy a crescent, Boucher, Bowen, Dacre, Heneage, Hungerford, Lacy, Stafford, Wake, and

Fig. 133.

Harrington used the knots that bear their names. Gower designates the great nobles of his day by their badges, as is done in the following satirical lines written about 1449:—

The rote¹ is ded, the swan² is goon,
The fiery cresset³ hath lost his lyght,
Therefore Ingland may mak gret mone,
Were not the helpe of God Almighty.
The castell⁴ is wonne, where care begoun
The portecolys⁵ is leyde a donn;
Yclosed we have oure Velvette hatte⁶,
That kepyd us from many stormys brown.
The white lion⁷ is leyde to slepe,
Thorough the envy of the ape clogge⁸,

and so on, through interminable further instances.

The Scottish clans wore native plants for their badges: Chisholm, the alder; Menzies, the ash; M'Intosli, the box, &c.

The Motto.—In times when each chief tenant under the crown brought his own tenants into the field, and led them,

distinct war-cries were common. The royal cry was "St George for England." The French cried, "Montjoye St Denis;" the *cri de guerre* of Bauffremont was their name; that of Barr, "Au feu"; Seyton, "St Bennet and Set on." The common Highland cry or slogan was "Claymore"; that of the Medici, "Palle, palle," alluding to their arms. The motto succeeded to this (1291); Bruce of Annandale used "Esto fortis in bello"; Courtenay, "Passez bien devant"; Hastings, "Honorantes me honorabo"; Kirkpatrick used the crest of the bloody dirk with the motto "I mak sicker." The Warren motto, alluding to the earls' resistance to the "quo warranto," was "tenebo;" Vernon, "God save the Vernon," ill exchanged for "Vernon semper viret." The Scottish borderers, who lived by harrying their neighbours by moonlight, used stars and crescents for their arms, and such mottos as "Reparabit cornu Phœbe" for Scott of Harden, or "Watch weel" of Halyburton. In modern times Sir Dudley Ryder died while his patent of peerage

FIG. 134.—Seal of Richard III.

FIG. 135.—Countersel of Richard III.

was under seal. It was given to his son, who adopted as a motto "Fides servata cineri."

Supporters are now placed on either side of the shield, and are usually animals or human figures. They seem to have arisen from the ornaments introduced by the seal engraver, and became heraldic with the practice of quartering. The seal of Edmund Crouchback bears a shield flanked by two wyverns, probably ornaments. That seal (1286) and the seal of Henry of Lancaster in 1300 contain both crest and helm, lambrequin and supporters. The seal of Catherine, queen of Henry IV., has two antelopes, and her husband as prince used two swans. At Naworth the family supporters, of gigantic size, support the principals of the roof of the hall. Under the house of Tudor many families of knightly rank, as Babington, Stanhope, and Luttrell, used supporters, but at this time supporters are only granted to peers, knights of the garter, grand crosses of the bath, Nova Scotia baronets, and a few private persons who hold them by prescription. In Scotland they are used by heads of clans and by a few lowland families. Fletcher of Saltoun uses two griffins.

Another appendage is the *Eagle*, upon which some North Wales families place their shields, and the double-headed variety so used by nobles of the Holy Roman empire.

¹ Duke of Bedford.

² Bohun, for duke of Gloucester.

³ Duke of Exeter.

⁴ Rouen.

⁵ Beauport, duke of Somerset.

⁶ Cardinal Wolsey.

⁷ Duke of Norfolk.

⁸ Duke of Suffolk.

The *Livery* has long lost its early signification, and is used only for the dress of the retainers in their lord's colour. At Richard III.'s coronation 8000 badges of the white boar were wrought upon liveries of fustian. A statute of Henry IV. forbade the use of liveries under heavy penalties, but they reappeared in the Wars of the Roses. Richard III. used "collars of livery," but these were for persons of rank. One remains upon a Neville effigy at Brancepeth.

Crowns, Coronets, and Symbols of Rank.—The crown is the head attire of a sovereign prince. It is usually closed at the top by four arched bars called diadems, and surmounted by a globe and cross. Edward IV. is said to have first closed the English crown. That now in use is a circle of gold, jewelled, edged above with crosses patée and fleurs-de-lys alternate, and closed above with four bars and the cross and globe called in Germany the Reichsapfel (fig. 136). Since the Restoration the crown of the Princes of Wales has been surmounted by two bars, also with the Reichsapfel (fig. 137). They also use the plume of three ostrich feathers, with the words "Ich dien," adopted by the Black Prince (fig. 138). Figs. 139 and 140 give representations of the imperial crown of Austria and the crown of the old kings of France. The Pope places three crowns over his mitre or tiara (fig. 141), said to have been severally assumed in 1295, 1335, and 1411. The crown imperial of Charlemagne may be seen on a scutcheon of pretence on the arms of Hanover, as the

elector's badge of arch-treasurer. The doges of Venice and Genoa bore a peculiar cap or toque, seen in Greek statuary, and upon the figures on the arch of Constantine.

Fig. 136.—Crown of England.

Fig. 137.—Crown of the Prince of Wales.

Fig. 138.

Fig. 139.—Crown of Austria.

The coronet is the head attire of a noble. In England those of princes of the blood are bordered with crosses

Fig. 140.—Crown of France (old).

Fig. 141.—The Pope's Crown.

Fig. 142.—The Sultan's Tiara.

patée and fleurs-de-lys under a regulation of 13 Charles II. (fig. 143). The princesses alternate the same ornaments with strawberry leaves (fig. 144).

The coronet of a duke is bordered with eight strawberry leaves (fig. 145); that of a marquis with four alternating with four pearls placed on low points (fig. 146).

Fig. 143.

Fig. 144.

An earl's coronet has eight strawberry leaves alternating with eight pearls upon tall points (fig. 147). The viscount borders his coronet with an indefinite number of pearls,

Fig. 145.

Fig. 146.

Fig. 147.

Fig. 148.

set close upon the rim (fig. 148). The baron's coronet, granted to the order by Charles II., carries six pearls placed on the rim at equal intervals,—four being seen at once (fig. 149). These coronets are all lined with ermine, and enriched with jewels. On occasions of state, when not worn by the peer, they are carried before him on a cushion. The eldest sons of peers above the rank of viscount wear the coronet due to their father's second title. The crowns of the kings-at-arms are of gold, bordered with and encircled by the motto "Miserere mei, Domine." The ducal, as an ancient form of coronet, is often used without reference to rank, as the base for a crest. It was so used by Sir Simon de Felbrigge in 1442.

A bishop has neither crest nor coronet, but ensigns his arms with a mitre. The bishops of Durham, while palatines, placed their mitre in a ducal coronet, as—though without authority—do the archbishops (fig. 150). The Berkeley crest is a mitre. The ancient mitre was low, and of linen stiffened with vellum. The central band and the margin, embroidered with fleurs-de-lys or other patterns, were called the orphreys. The pendent side ribbons were the "infule." Prelates of the church of Rome ensign their shields with a hat, the tassels of which indicate their rank. A cardinal has four rows of red tassels, arranged 1, 2, 4, 8, or 15 on each side; an archbishop the same, but green. A bishop has three rows, an abbot two; the abbot's hat is black. Prelates and legates place a patriarchal cross in pale behind their shield.

The *Helmet* also indicates the rank of the wearer. It

Fig. 150.

is placed above the shield, and beneath the crest. The sovereign and the royal family bear the helmet full-faced or affrontée with six bars, all of gold (fig. 151). Those of dukes and marquises are of gold with five steel bars (fig.

Fig. 151.

Fig. 152.

Fig. 153.

Fig. 154.

152). The lesser nobles have silver helmets borne in profile with gold ornaments and four silver bars. Those of baronets and knights are of steel, full-faced and open (fig. 153). An esquire's helmet is of steel, represented in profile, with the vizor closed (fig. 154). These distinctions were probably introduced after the Restoration.

The *Mantling* is a sort of cloak or mantle of fur extended behind the shield, and sufficiently ample to include the whole achievement. Those of sovereigns are of gold doubled with ermine, and are called "pavillons." Peers' mantlings are of crimson velvet, doubled with white fur and barred with ermine spots; a duke has four bars, a marquis three and a half, an earl three, a viscount two and a half, and a baron two. Commoners use red mantlings lined with white fur. The prior of St John, whose place was on the right of the temporal barons, used a sable mantling doubled with murrey. The pavillon of France was of blue velvet, powdered with gold fleurs-de-lys, and lined with ermine. Such a mantling may be seen behind the arms of Beaumont in Rothley Temple chapel, in right of their descent from the blood-royal of France.

Certain officers of state accompanied their armorial shields with exterior marks of their rank. The Earl Marshal placed two truncheons saltirewise behind his shield, tipped above with the arms of England, and below with his own arms. His deputy places one truncheon in bend dexter.

In Scotland the Lord High Constable, the earl of Errol, places on either side of his shield an arm issuant from a cloud, and grasping a sword. Under the old monarchy the French colonels commandant placed the standards of their regiments saltirewise behind their shields.

The Lords High Admiral have been variously distinguished. Thomas de Berkeley bears on his brass a collar of fritons. Thomas, duke of Exeter, sealed with a ship and his arms on the mainsail. The anchor in some form or other was a common emblem.

Merchants' marks are scarcely heraldic, though they took the place of arms with the trading classes. They were usually monograms of the name or initials. They were protected by law as marks on goods, and are seen on merchants' tombs and sometimes in architecture.

FUNERAL ESCUTCHEONS.

Some of the most valuable records in the College of Arms are the certificates of funerals conducted under their superintendence and authority. These gorgeous and expensive ceremonials have happily fallen into disuse, save on very rare occasions, and for royal persons or eminent public characters. The last private funeral conducted with anything like the ancient ceremonial was that of Charles, earl of Shrovesbury, in 1828. All that is now usual is the suspension of a shield of arms in a large black lozenge-shaped frame called a hatchment or achievement against the wall of the house of the deceased. It is usually placed over the entrance at the level of the second floor, and remains for from six to twelve months, when it is removed to the parish church. Even this custom, scarcely consistent with living in hired houses and burying in cemeteries, is falling into disuse, though still not uncommon.

If for a bachelor, the hatchment bears upon a shield his arms, crest, and other appendages, the whole on a black ground. If for a single

woman her arms are represented upon a lozenge, bordered with knotted ribbons, also on a black ground. If the hatchment be for a married man (as in fig. 155), his arms upon a shield impale those of his wife; or if she be an heiress they are placed upon a scutcheon of pretence, and crest and other appendages are added. The dexter half of the ground is black, the sinister white. For a wife whose husband is alive the same arrangement is used, but the sinister ground only is black. For a widower the same is used as for a married man, but the whole ground is black; for a widow the husband's arms are given with her own, but upon a lozenge, with ribbons, without crest or appendages, and the whole ground is black. When there have been two wives or two husbands the ground is divided into three parts per pale, and the division behind the arms of the survivor is white. Colours and military or naval emblems are sometimes placed behind the arms of military or naval officers. It is thus easy to discern from the hatchment the sex, condition, and quality, and possibly the name of the deceased.

In Scottish hatchments it is not unusual to place the arms of the father and mother of the deceased in the two

Fig. 155.

lateral angles of the lozenge, and sometimes the 4, 8, or 16 genealogical escutcheons are ranged along the margin.

Undertakers are fond of substituting "In cœlo quies" or some such commonplace for the family motto. This is irregular.

The literature of heraldry commences with the treatises of Sassoferrato about 1358, De Fosso in the reign of Richard II., and Upton about 1441, all written in Latin and printed by Sir E. Bysshe in 1654. They are followed by the *Boke of St Albans*, written by Dame Juliana Berners, prioress of Sopwell, and printed in 1486. These, especially those of Upton and Dame Juliana, are valuable. The lady writes in a mixture of early English and Latin, but her descriptions are intelligible and copious. These writers were followed by a crowd of others, of whom the chief were Gerard Leigh, Ferne, and Morgan, who wrote in the latter half of the 16th century. Their great aim was to elevate their subject by tracing back the use of armories to the patriarchs and heroes of Jewish and pagan antiquity, whom they invested with coats of arms on the type of those used by Norman barons. There are traces of this folly in Dame Juliana, but it reached its height in the writings of her successors, and was not quite extinguished when Guillim wrote his *Display of Heraldry* in 1610. Guillim, whose work is still a standard, wrote in English, but as late as 1654 and 1688 Spelman, in his *Aspilogia*, and John Gibbon strove hard to restore the use of a dead language upon a subject to which it was eminently unsuitable. In 1722 and 1780 were published the excellent volumes of Nisbet, chiefly relating to Scotland, and of Edmondson, whose list or ordinary of bearings was long very useful to those who seek to identify the name to which a coat belongs, until superseded by the very laborious and far more complete work of Papworth.

Recently the same critical spirit that has pervaded the work of our historians has been applied with equal diligence to the whole subject of heraldry; a number of authors, led by Planché, Boutell, Seton, Nichols, and Lower, have set aside all the fabulous pretensions and baseless assertions of the earlier writers, have sifted the old evidence and adduced much that is new. The whole subject of heraldic and quasi-heraldic seals has been brought under notice by the publication of Laing's fine plates of Scottish seals; and it may truly be said that the real origin and growth of the use of armorial bearings is placed before the reader in the books of these writers in a truthful and most attractive form. (G. T. C.)

FIG. 156.—Arms of the Dukes of Marlborough.

The above figure represents the armorial achievement of the dukes of Marlborough, princes of the Holy Roman Empire and of Mindelheim in Swabia. The arms are quarterly—1 and 4, Churchill, sable, a lion rampant, and on a canton argent a cross of St George; 2 and 3, Spencer, quarterly argent and gules, in the second and third a fret or, over all on a bend sable 3 escallops of the first; in chief, as an augmentation, upon an escutcheon of pretence argent a cross of St George, charged with an inescutcheon azure, 3 fleurs-de-lys or; the whole contained within the garter, ensigned with a ducal coronet, and placed upon the breast of an imperial eagle. Crests—1, Churchill, a lion couchant gardant argent, supporting with his dexter paw a banner gules, thereon a dexter hand coupé above of the first, staff or; 2, Spencer, out of a ducal coronet or a griffin's head argent, armed or, gorged with a bar gemelle gules, between two wings expanded of the second. Between the crests the closed crown of a prince of the empire. Supporters—two wyverns argent, wings expanded. Motto—"Fiel pero desdichado."

HERAT is a city of great interest both historically and geographically, and is of even greater interest politically, its importance at the present day being indicated by its popular designation of the "key of India." Its origin is lost in antiquity. The name first appears in the list of primitive Zoroastrian settlements contained in the *Vendidad Sadé*, where, however, like most of the names in the same list,—such as *Sughdu* (Sogdia), *Mourá* (Merv or Margus), *Haraquti* (Arachotus or Arghend-ab), *Haetumant* (Etymander or Helmand), and *Ragha* (or Argha-stán),—it seems to apply to the river or river-basin, which was the special centre of population. This name of *Haroyu*, as it is written in the *Vendidad*, or *Hariwa*, as it appears in the inscriptions of Darius, is a cognate form with the Sanskrit *Sarayu*, which signifies "a river," and its resemblance to the ethnic title of Aryan (Sans. *Arya*) is purely fortuitous; though from the circumstance of the city being named "Aria Metropolis" by the Greeks, and being also recognized as the capital of Ariana, "the country of the Arians," the two forms have been frequently confounded. Of the foundation of Herat (or Heri, as it is still often called) nothing is known. We can only infer from the colossal character of the earth-works which surround the modern town, that, like the similar remains at Bost on the Helmand and at Ulán Robát of Arachosia, they belong to that period of Central-Asian history which preceded the rise of Achæmænian power, and which in Grecian romance is illustrated by the names of Bacchus, of Hercules, and of Semiramis.

The natural advantages of Herat are mainly due to its river, which, rising in the high uplands 350 miles to the eastward, where the Koh-i-Bábá, the prolongation of the Hindú-kúsh, bifurcates into the two parallel ranges of the Safid-koh or "white mountains" to the north and the Siyáh-koh or "black mountains" to the south, passes in the upper part of its course through a succession of rolling downs of the finest pasture-land, and lower down traverses a more contracted valley, enlivened, however, throughout with smiling villages and orchards, till it reaches the eastern limit of the alluvial plain of Herat. Here at the present day nine large canals (in former times there were twenty) carry off the waters of the Heri-rúd for the irrigation of the circumjacent plain, which on a rough calculation may be said to contain nearly 400 square miles of land available for cultivation. M. Khanikoff, who visited Herat in 1858, observes that nowhere in the East,—not even at Samarcand or Bokhara or Ispahán, where the art of canalization is supposed to be carried to perfection,—had he seen water-courses constructed with so much skill, or maintained with so much care, as in the valley of the Heri-rúd; and he adds that, although at the period of his visit nine-tenths of the villages of the plain, which in ordinary times amount to nearly 500, were partially in ruins and the adjoining fields laid waste, the cereal produce of the remaining lands was still far in excess of the wants of the settled inhabitants. The Heri-rúd, passing between 3 and 4 miles to the south of Herat, where it is spanned by a magnificent bridge of twenty-three arches, called the *Pál-i-Malán*, continues its course westward to the extremity of this rich and fertile plain; it then turns north through an arid country for some 200 miles to Sarakhs, receiving two small streams from the west, the Áb-i-Jám and Áb-i-Meshed, and forming the territorial boundary between Persia and Afghanistan. As the Heri-rúd is formed of the converging drainage of the Safid-koh and Siyáh-koh ranges, and its volume thus depends on the extent of snow that falls in the mountains, it is impossible to define with any exactitude the limit of its northern course; but in ordinary seasons water is rarely found in the river bed beyond Sarakhs, and never does the stream penetrate to the northward of a line uniting Abiverd and Merv;

and it is of the more importance to note this geographical feature, as in many of our modern maps the line of the Heri-rúd, or Tejend, as it is called in its lower course, is prolonged through the desert 200 miles to the north-westward of Sarakhs.

The city of Herat is in 34° 22' N. lat. and 62° 9' E. long. It is very centrally situated, great lines of communication radiating from it in all directions—southward to Seistan (200 miles), south-eastward to Kandahar (370 miles), eastward to Cabul (550 miles), northward by Mymeneh to Bokhara (600 miles) and by Merv to Khiva (700 miles), while to the westward four routes lead into Persia by Turbat to Meshed (215 miles), and by Birjend to Kermán (400 miles), to Yezd (500 miles), or to Ispahán (600 miles). The city forms a quadrangle of nearly a mile square (more accurately about 1600 yards by 1500 yards); on the western, southern, and eastern faces the line of defence is almost straight, the only projecting points being the gateways, but on the northern face the contour is broken by a double outwork, consisting of the *Ark* or citadel, which is built of sun-dried brick on a high artificial mound within the enceinte, and a lower work at its foot, called the *Ark-i-nou*, or "new citadel," which extends 100 yards beyond the line of the city wall. That which distinguishes Herat from all other Oriental cities, and at the same time constitutes its main defence, is the stupendous character of the earthwork upon which the city wall is built. This earthwork averages 250 feet in width at the base and about 50 feet in height, and as it is crowned by a wall 25 feet high and 14 feet thick at the base, supported by about 150 semi-circular towers, and is further protected by a ditch 45 feet in width and 16 in depth, it presents an appearance of imposing strength. Whether the place is really as strong as it looks has been differently estimated. General Ferrier, who resided for some time in Herat in 1846, states that the city is nothing more than an immense redoubt, and gives it as his opinion that as the line of wall is entirely without flanking defences, the place could not hold out for twenty days against a European army; and M. Khanikoff, who, though not a professional soldier, was a very acute observer, further remarks that the whole interior of the city is dominated from the rising ground at the north-east angle, while the water supply both for the ditch and the city would be at the mercy of an enemy holding the outside country, the wells and reservoirs inside the wall, which would then be alone available, being quite inadequate to the wants of the inhabitants; but on the other hand all experience testifies to the defensibility of the position. Not to speak of the sieges which Herat sustained at the hands of Jenghiz Khan, of Timur, and of Ahmed Shah, we have only to remember that in 1837 the Afghans of Herat beat off the continuous attack for nearly ten months of a Persian army of 35,000 regular troops, supported by 50 pieces of artillery, and in many cases directed and even commanded by Russian officers. The truth seems to be that Herat, though in its present state quite unfit to resist a European army, possesses great capabilities of defence, and might by a skilful adaptation of the resources of modern science be made almost impregnable. A British engineer officer, Major Sanders, calculated in 1840 that at an outlay of sixty or seventy thousand pounds, which would include the expense of deepening the ditch, clearing the glacis and esplanade, providing flanking defences and repairing two walls, &c., throughout, Herat might be rendered secure against any possible renewal of the attack by Persia; but of course if an attack by a well-appointed European army were anticipated, more extensive preparations for defence would be required, including probably the erection of two independent forts on the high ground at Mosallá and Thaleh-bengi.

The city possesses five gates, two on the northern face, the Kutab-chak near the north-east angle of the wall, and the Malik at the re-entering angle of the Ark-i-now; and three others in the centres of the remaining faces, the Irak gate on the west, the Kandahar gate on the south, and the Khushk gate on the east face. Four streets called the *Chahar-suk*, and running from the centre of each face, meet in the centre of the town in a small domed quadrangle. The principal street runs from the south or Kandahar gate to the market in front of the citadel, and is covered in with a vaulted roof through its entire length, the shops and buildings of this bazaar being much superior to those of the other streets, and the merchants' caravanserais, several of which are spacious and well built, all opening out on this great thoroughfare. Near the central quadrangle of the city is a vast reservoir of water, the dome of which is of bold and excellent proportions. It is stated by General Ferrier to have been constructed by command of Shah Abbas, and to be a *chef d'œuvre* of its kind. It is supposed to contain above a twelve months' supply of water for the entire city, but, as M. Khanikoff observes, it is within easy mortar range of the high ground at the north-east angle of the city, and might thus be destroyed by a few well-directed shells, in which case the ruins of the dome would fill up the basin and the water supply would be lost. The only other public building of any consequence in Herat is the great mosque or *Mesjid-i-Juma*, which comprises an area of 800 yards square, and must have been a most magnificent structure. It was erected towards the close of the 15th century, during the reign of Shah Sultan Hussein of the family of Timur, and is said when perfect to have been 465 feet long by 275 feet wide, to have had 408 cupolas, 130 windows, 444 pillars, and 6 entrances, and to have been adorned in the most magnificent manner with gilding, carving, precious mosaics, and other elaborate and costly embellishments. Now, however, it is falling rapidly into ruin, the ever-changing provincial governors who administer Herat having neither the means nor the inclination to undertake the necessary repairs. Neither the palace of the Charbagh within the city wall, which was the residence of the British mission in 1840-41, nor the royal quarters in the citadel deserve any special notice. At the present day, with the exception of the *Chahar-suk*, where there is always a certain amount of traffic, and where the great diversity of race and costume imparts much liveliness to the scene, Herat presents a very melancholy and desolate appearance. The mud houses in rear of the bazaars are for the most part uninhabited and in ruins, and even the burnt brick buildings are becoming everywhere dilapidated. The city is besides one of the filthiest in the East, as there are no means of drainage or sewerage, and garbage of every description lies in heaps in the open streets.

With regard to the population, it fluctuates so rapidly, according to the circumstances of the period, that it is impossible to give any estimate of its normal strength. When Christie visited the city in 1809 it was in a very prosperous condition, having been undisturbed for fifty years, and was supposed to contain 100,000 inhabitants. A. Conolly in 1828 reduced the numbers to 45,000. Before the Persian siege in 1837 the population was estimated at 70,000, but at the close of the war 6000 or 7000 were all that remained. In 1845, at the time of General Ferrier's visit, the numbers had increased again to 22,000, and continued to increase to the time of the capture of the place by Dost Mahomed Khan in 1863, when there were at least 50,000 inhabitants within the walls. Since that time Herat has been a mere provincial city governed from Cabul, and its average population has ranged between 20,000 and 30,000, within which limits must be confined its present estimate.

The maximum population of which the enceinte would seem to be capable may be put at Christie's estimate of 100,000, and it is manifest therefore that when Herat contained a population of a million and a half, as is testified by so many contemporary authorities, the present city could have been only the citadel of this vast metropolis, the great mass of buildings lying along the slopes of the northern-hills, where for a space of some 4 miles in length by 3 miles in breadth the surface of the plain, strewn over its whole extent with pieces of pottery and crumbling bricks, is also broken here and there by earthen mounds and ruined walls, the debris of palatial structures which at one time were the glory and wonder of the East. Of these structures indeed some have survived to the present day in a sufficiently perfect state to bear witness to the grandeur and beauty of the old architecture of Herat. The mosque of the Mosellá, for instance, originally built in the 12th century, but restored or rather rebuilt at the end of the 15th century, and intended for the reception of the body of the Imam Reza which Shah Sultan Hussein wished to remove from Meshed to Herat, is, even in its present state of ruin and decay, one of the most imposing and elegant structures to be seen in Asia. "The mosque," says General Ferrier, "is completely covered with a mosaic of glazed bricks in varied and beautiful patterns, and the cupola is of amazing dimensions. Several arcades supported by pillars in brick equal the proportions of the arch of Ctesiphon, and the seven magnificent minarets that surround it may be said to be intact, for the upper part of them only is slightly injured." Scarcely inferior in beauty of design and execution, though of more moderate dimensions, is the tomb of the saint Abdullah Ansári, in the same neighbourhood. This building, which was erected by Shah Rokh Mirza, the grandson of Timur, nearly 500 years ago, contains some exquisite specimens of sculpture in the best style of Oriental art. Adjoining the tomb also are numerous marble mausoleums, the sepulchres of princes of the house of Timur; and especially deserving of notice is a royal building tastefully decorated by an Italian artist named Geralki, who was in the service of Shah Abbas the Great. The locality, which is further enlivened by gardens and running streams, is named *Gazir-gáh*, and is a favourite resort of the Heratis. It is held indeed in high veneration by all classes, and the famous Dost Mahomed Khan is himself buried at the foot of the tomb of the saint. Two other royal palaces named respectively *Bagh-i-Shah* and *Takht-i-Sefer*, are situated on the same rising ground somewhat further to the west. The buildings are now in ruins, but the view from the pavilions, shaded by splendid plane trees on the terraced gardens formed on the slope of the mountain, is said to be very beautiful.

The population of Herat and the neighbourhood is of a very mixed character. The original inhabitants of Ariana were no doubt of the Aryan family, and immediately cognate with the Persian race, but they were probably intermixed at a very early period with the Sacæ and Massagetae, who seem to have held the mountains from Cabul to Herat from the first dawn of history, and to whom must be ascribed—rather than to an infusion of Turco-Tartaric blood introduced by the armies of Jenghiz and Timur—the peculiar broad features and flattish countenance which distinguish the inhabitants of Herat, Seistan, and the eastern provinces of Persia from their countrymen further to the west. Under the government of Herat, however, there are a very large number of tribes, ruled over by separate and semi-independent chiefs, and belonging probably to different nationalities. The principal group of tribes is called the *Chahar-Aimák*, or "four races," the constituent parts of which, however, are variously stated by different authorities both as to strength and nomenclature. Mount Stuart Elphinstone, by far the best general authority on Afghan questions, gives the original four tribes as the Taimenis, the Hazárehs, the Taimúris, and Zúris; Khanikoff, on the other hand, whose forte was ethnography, and who made his inquiries on the spot, describes the *Chahar-Aimák* as the Kipchaks (100,000 families), the Jamshídis (12,000), the Taimenis (60,000), and the Firoz-kohis (10,000 to 12,000); while Pottinger substitutes the Sooni Hazárehs of Kilehnow for the Kipchaks of Khanikoff, and raises the Firoz-kohi Aimáks to 30,000 families. These tribes all dwell in the mountains to the north-east, the east, and the south-east of Herat, and number in the aggregate perhaps a million souls. Major Taylor, who made special inquiries on the subject in 1856, found that the governor of Herat could raise for fighting purposes from these tribes and the allied Turcomans of Merv 47,000 horse and 23,000 foot, but matters have very much changed since Herat came under the government of Cabul in 1863, the recent policy being to lower the fighting force of the semi-independent chiefs, and to substitute infantry regiments raised and paid by the central authority. At present there are perhaps ten such regiments, which can be supplemented by about 10,000 horse and 10,000 irregular foot.

The trade of Herat is also subject to great fluctuation. From its central geographical position it must naturally be an emporium of commerce between Persia, Turkestan, Afghanistan, and India, while owing to the richness of the valley, which can usually furnish supplies for 150,000 men over and above the consumption of

(the fixed inhabitants, as well as to the mineral wealth of the adjoining mountains and the industrial activity of the city population, especially in regard to silk and woollen manufactures (the carpets of Herat being famous throughout the East), the country rapidly recovers from the effects of war, and its normal condition may be said to be that of prosperity and abundance.

In actual territory Herat extends east and west from near the sources of the Heri-rūd about 300 miles to the Persian frontier beyond Ghorīān, and north and south from the Merv boundary, in about 36° lat., 200 miles to the northern limit of Seistan. The inhabitants of the city of Herat are for the most part Shiāhs, and in regard to language and habits, as well as religion, are Persians rather than Afghans. There are, however, both in the town and in the neighbouring villages a certain number of Afghan colonists, who have been settled there—the greater part by Nadir Shah—during the last 150 years, as well as Hazārehs, Jamshīdis, and Taimenis, with a fair sprinkling of Hindus and some forty families of Jews. The net revenue of the valley and its immediate dependencies in ordinary times is under £100,000 per annum, but the vizier Yar Mahomed Khan is supposed in the plenitude of his power, and when he had for a time brought a great part of Seistan under his sway, to have realized double that amount from the entire province.

To trace in any detail the fortunes of Herat would be to write the modern history of the East, for there has hardly been a dynastic revolution, or a foreign invasion, or a great civil war in Central Asia since the time of the Prophet, in which Herat has not played a conspicuous part and suffered accordingly. Under the Tahirides of Khorassan, the Soffarians of Seistan, and the Samanides of Bokhara, it flourished for some centuries in peace and progressive prosperity; but during the succeeding rule of the Ghaznevide kings its metropolitan character was for a time obscured by the celebrity of the neighbouring capital of Ghazni, until finally in the reign of Sultan Sanjar of Merv about 1157 the city was entirely destroyed by an irruption of the Ghoz, the predecessors, in race as well as in habitat, of the modern Turcomans. Herat gradually recovered under the enlightened Ghoride kings, who were indeed natives of the province, though they preferred to hold their court amid their ancestral fortresses in the mountains of Ghor, so that at the time of Jenghiz Khan's invasion it equalled or even exceeded in populousness and wealth its sister capitals of Balkh, Merv, and Nishapoor, the united strength of the four cities being estimated at three millions of inhabitants. But this Moghul visitation was most calamitous; forty persons, indeed, are stated to have alone survived the general massacre of 1232, and as a similar catastrophe overtook the city at the hands of Timur in 1398, when the local dynasty of Kurt which had succeeded the Ghorides in eastern Khorassan was put an end to, it is astonishing to find that early in the 15th century Herat was again flourishing and populous, and the favoured seat of the art and literature of the East. It was indeed under the princes of the house of Timūr that most of the noble buildings were erected, of which the remains still excite our admiration at Herat, while all the great historical works relative to Asia, such as the *Rozet-es-Sefā*, the *Habib-es-seir*, *Hafiz Abrū's Tarikh*, the *Matlā'a-es-Sa'adin*, &c., date from the same place and the same age. Four times was Herat sacked by Tarcomans and Uzbegs during the centuries which intervened between the Timuride princes and the rise of the Afghan power, and it has never in modern times attained to anything like its old importance. Afghan tribes, who had originally dwelt far to the east, were first settled at Herat by Nadir Shah, and from that time they have monopolized the government and formed the dominant element in the population. It will be needless to trace the revolutions and counter-revolutions which have followed each other in quick succession at Herat since Ahmed Shah Durāni founded the Afghan monarchy about the middle of the last century. Let it suffice to say that Herat has been throughout the seat of an Afghan government, sometimes in subordination to Cabul and sometimes independent. Persia indeed for many years showed a strong disposition to reassert the supremacy over Herat which was exercised by the Saffavean kings, but Great Britain, disapproving of the advance of Persia towards the Indian frontier, steadily resisted the encroachment; and, indeed, after helping the Herātis to beat off the attack of the Persian army in 1838, the British at length compelled the shah in 1857 at the close of his war with them to sign a treaty recognizing the future independence of the place, and pledging Persia against any further interference with the Afghans. In 1843 Herat, which for fifty years previously had been independent of Cabul, was incorporated by Dost Mahomed Khan in the Afghan monarchy, and such is the present condition of the principality, the actual Governor Ayūb Khan being the uterine brother and deputy of Yacūb Khan, who recently signed with the Government of India the famous treaty of Gandamak. (H. C. R.)

HÉRAULT, a department in the south of France, formed from parts of the old province of Languedoc, is bounded on the N.E. by Gard, N.W. by Aveyron and Tarn, and S. by Aude and the Gulf of Lyons. It has an area of 2444 square miles, and is situated between 43° 10' and 44° N.

lat., 2° 30' and 4° 10' E. long. Its greatest length is 84 miles, and its greatest breadth 50. About a third of the department consists of moorland, heath, and common, a fourth of arable land, a sixth of vineyards, and an eighth of wood. The southern prolongation of the Cevennes mountains forms the north boundary of the department. The highest point is about 4250 feet above the sea-level. The ridge forms the watershed between the waters of the Atlantic and the Mediterranean, and from it there flow the Vidourle, Mosson, Hérault, Livron, and Orb. Of these the Hérault, 80 miles long, is the chief, and gives name to the department. The Vidourle forms the boundary between the department and that of Gard. The high mountains of the north are partly barren, partly wooded. In the extensive plains of the centre the vine and olive flourish, and figs, mulberries, and other fruit-trees are to be met with nearly in all parts. Grain is chiefly produced in the south. The soil of the north is chalky clay, of the centre light gravel, and of the south a strong rich loam. The "garrigues" are considerable portions of waste land, covered with heath and shrubs. St Loup, Couques, and St Thibéry, the first of which is 750 feet high, are extinct volcanic cones. The greater part of the south coast consists of a series of salt marshes, separated from the sea by a narrow strip of land. The marsh of Thau, the largest, stretches from the mouth of the Hérault, and communicates, through the marsh of Frontignan, with that of Mauguio, on the eastern frontier of the department. The Canal du Midi, after stretching about 30 miles into the department, terminates at Agde. From Certe the navigation is kept up through the marshes by the canals of Agde and Radelle to Aigues Mortes. The coast line of the department is 66 miles long. In the valleys and at the foot of the mountains the climate is delightfully mild. Fish abound in the salt marshes. The vegetable productions comprise aromatic and dyeing plants; the ilex oak prevails in the forests. The mineral wealth of the department is considerable. Mines of lignite, coal, iron, copper, and lead are wrought. It produces magnificent blocks of marble, also alabaster, gypsum, granite, sand stone, potters' clay, alum; and the marshes supply France with salt. At Gabian there is a petroleum well. Wine and oil constitute the chief agricultural wealth of the department. The red wines of St Georges, St Drézéry, St Christol, and the white wines of Frontignan and Lunel, are held in high estimation. Considerable quantities of wheat, oats, and potatoes are grown. There is a large amount of excellent pasturage, and horses and sheep are extensively reared. Mulberries, pomegranates, figs, raisins and other dried fruits, and olives are prepared for exportation. The chief manufactures are woollen and cotton cloth, silk, perfumery, soap, and chemical substances. The department has Montpellier for its capital, and is divided into the arrondissements of Montpellier, Béziers, Lodève, and St Pons, with 36 cantons and 331 communes. The population was 429,878 in 1872, and 445,053 in 1876.

HERBARIUM, or **HORTUS SICCUS**, a collection of plants so dried and preserved as fully to illustrate their several specific characters. Since the same plant, owing to peculiarities of climate, soil, and situation, degree of exposure to light, and other influences, may vary greatly according to the locality in which it occurs, it is only by gathering together for comparison and study a large series of examples of each species illustrative of the flora of different regions that the laws of vegetable morphology, and many more points of scientific interest, can be satisfactorily determined. Thus, from the herbarium may be acquired a knowledge of those details concerning the minuter structure of individual plants which are of necessity omitted in works of systematic botany, as also of the relative taxonomic importance of the characters to be met with in large groups of forms.

Commencing with British herbaria, the collection of the Royal Herbarium at Kew, generally acknowledged to be at once the most extensive and the best preserved and most orderly in the world, comprises some 100,000 species, many of them represented by numerous specimens. It is arranged, for easy reference, in cases situate between the windows of the building containing it, the atmosphere of which is kept dry by means of hot-water pipes. In the intervening spaces are tables for the purpose of study, which is further facilitated by the presence in the same building of a large and valuable botanical library. Next in importance is the herbarium of the British Museum, which comprises assemblages of specimens gathered by numerous eminent botanists. The collection of Dillenius is deposited at Oxford, and that of the late Professor Harvey at Trinity College, Dublin. The original herbarium of Linnæus is in the possession of the Linnean Society of London. With the more important British herbaria are to be ranked also those of Cambridge and Edinburgh. The collections of Jussieu and St Hilaire are included in the large herbarium of the Jardin des Plantes at Paris, and in the same city is the extensive private collection of Dr Cosson. At Geneva are three large collections,—De Candolle's, containing the typical specimens of the *Prodromus*, Delessert's fine series, and Boissier's Mediterranean and Oriental plants. The university of Göttingen has had bequeathed to it the largest collection (exceeding 40,000 specimens) ever made by a single individual—that of the late Professor Grisebach. At the herbarium in Brussels are the specimens obtained by the traveller Martius, the majority of which formed the groundwork of his *Flora Brasiliensis*. Other national herbaria sufficiently extensive to subserve the requirements of the systematic botanist exist at Berlin, St Petersburg, Vienna, Leyden, Stockholm, Upsala, Copenhagen, and Florence. Of those in the United States of America, the chief, formed by Asa Gray, is the property of Harvard university; others are to be seen at Yale and Columbia colleges and at New York and Michigan universities. The herbarium at Melbourne, Australia, under Baron Müller, has attained large proportions; and that of the Botanical Garden of Calcutta is noteworthy as the repository of numerous specimens described by writers on Indian botany.

Specimens of flowering plants and vascular cryptogams are, at Kew, generally mounted on sheets of stout smooth paper, of uniform quality, and in most cases 17 inches long by 11 inches broad; the palms and their allies, however, and some ferns, require a size of 22 by 14 inches. The tough but flexible coarse grey paper (German, *Fliesspapier*), upon which on the Continent specimens are commonly fixed by gummed strips of the same, is less hygroscopic than ordinary cartridge paper, but has the disadvantage of affording harbourage in the inequalities of its surface to a minute insect, *Atropos pulsatoria*, L., which commits great havoc in damp specimens, and which, even if noticed, cannot be dislodged without difficulty. The majority of plant specimens are most suitably fastened on paper by a mixture of equal parts of gum tragacanth and gum arabic made into a thick paste with water. Rigid leathery leaves are affixed by means of glue, or, if they present too smooth a surface, by stitching at their edges. Where, as in private herbaria, the specimens are not liable to be handled with great frequency, a stitch here and there round the stem, tied at the back of the sheet, or slips of paper passed over the stem through two slits in the sheet and attached with gum to its back, or simply strips of gummed paper laid across the stem, may be resorted to. A new adhesive substance, a kind of fish glue, has lately come into use for this purpose, and is highly spoken of. To preserve from insects, the plants, after mounting, are brushed over with

a liquid formed by the solution of $\frac{1}{4}$ lb each of corrosive sublimate and carbolic acid in 1 gallon of methylated spirits. They are then laid out to dry on shelves made of a network of stout galvanized iron wire. After this are written, usually in the right-hand corner of the sheet, or on a label there affixed, the designation of each species, the date and place of gathering, and the name of the collector. Information as to economical or medicinal properties may either be added thereto, or mentioned on the back of the sheet. It is especially important to attach to the name of the plant the initials or abbreviated name of the author by whom it was first described; e.g., the words *Uva lactuca* alone, might signify either of two distinct plants, the one described by Linnæus, the other by Agardh. When the generic name has been altered, but the specific name has been retained, the name of the original describer of the plant is placed in brackets before the name of the later author. Thus the *Enteromorpha Grevillei* of Thuret, having been renamed, has become *Ulva Grevillei* (Thur.), Le Jolis. The value of specimens in private herbaria is greatly enhanced by briefly stating on the lower left-hand corner of the sheet the characters that distinguish it from the plants most nearly resembling it. Other particulars as to habit, local abundance, soil, and claim to be indigenous may be written on the back of the sheet, or on a slip of writing paper attached to its edge. It is convenient to place in a small envelope gummed to an upper corner of the sheet any flowers, seeds, or leaves needed for dissection or microscopical examination, especially where from the fixation of the specimen it is impossible to examine the leaves for oil-receptacles, and where seed is apt to escape from ripe capsules and be lost. The addition of a careful dissection of a flower greatly increases the value of the specimen. To ensure that all shall lie evenly in the herbarium the plants should be made to occupy as far as possible alternately the right and left sides of their respective sheets. The species of each genus are then arranged either systematically or alphabetically in separate covers of stout, usually light brown paper, or, if the genus be large, in several covers with the name of the genus clearly indicated in the lower left-hand corner of each, and opposite it the names or reference numbers of the species. Undetermined species are relegated to the end of the genus. Thus prepared, the specimens are placed on shelves or movable trays, at intervals of about 6 inches, in an air-tight cupboard, on the inner side of the door of which, as a special protection against insects, is suspended a muslin bag containing a piece of camphor.

The systematic arrangement varies in different herbaria. The works usually followed are—for dicotyledons, De Candolle's *Prodromus*, and Endlicher's or Bentham and Hooker's *Genera Plantarum*; for monocotyledons, Kunth's *Enumeratio*; for ferns, Hooker and Baker's *Synopsis Filicum*; for mosses, Müller's *Synopsis Muscorum Frondosorum*; for algæ, Kützing's *Phycologia generalis*; for hepaticæ, Gottschie, Lindenberg, and Nees ab Esenbeck's *Synopsis Hepaticarum*; and for other groups of cryptogamic plants the treatises of various authors scattered through numerous scientific publications. In certain herbaria, as in those of Boissier and Delessert at Geneva, the authority of the *Prodromus* is accepted only in the absence of any more recent treatise, or of a complete monograph on a family. For the members of large genera, e.g., *Piper* and *Ficus*, since the number of cosmopolitan or very widely distributed species is comparatively few, a geographical grouping is found specially convenient by those who are constantly receiving parcels of plants from known foreign sources. The ordinary systematic arrangement possesses the great advantage, in the case of large genera, of readily

indicating the affinities of any particular specimen with the forms most nearly allied to it in type. In the United States the species in the genera, and the genera in the orders, are usually arranged alphabetically, and the orders serially; sometimes, however, the genera are placed alphabetically throughout without reference to the orders. The alphabetical arrangement, provided works on systematic botany are referred to for the identification of particular plants, possesses the advantage of permitting ready reference to any given species, and also of being independent of changes of classification; but in Europe it is rarely adopted, on account of the counterbalancing practical inconveniences it is considered to present. Instead of keeping a catalogue of the species contained in the herbarium, which, owing to the constant additions, would be almost impossible, such species are usually ticked off with a pencil in the systematic work which is followed in arranging them, so that by reference to this work it is possible to see at a glance whether the specimen sought is in the herbarium, and what species are still wanted. The custom commonly prevalent in Continental, especially German, herbaria of placing the dried specimens loosely between sheets of papers not always of uniform character is liable to lead to the admixture of nearly allied forms in intricate genera, such as *Rubus*, *Rosa*, *Hieracium*, *Salix*, &c., unless a label is attached to each specimen, a precaution not always adopted. In Germany Endlicher's system is much followed for flowering plants, with the exception of palms, for which Martius's arrangement is preferred. At Geneva De Candolle's original herbarium is arranged in exact accordance with his *Prodromus*. In the other large herbaria in that city, the mounting and arrangement of the specimens are conducted much as in England, with the exception that smaller-sized sheets of paper are used for cryptogams.

Specimens intended for the herbarium should be collected when possible in dry weather, care being taken to select plants or portions of plants in sufficient number and of a size adequate to illustrate all the characteristic features of the species. When the root-leaves and roots present any peculiarities, they should invariably be collected, but the roots should be dried separately in an oven at a moderate heat. Roots and fruits too bulky to be placed on the sheets of the herbarium may be conveniently arranged in glass-covered boxes contained in drawers. The best and most effective mode of drying specimens is learned only by experience, different species requiring special treatment according to their several peculiarities. The chief points to be attended to are to have a plentiful supply of botanical drying paper, so as to be able to use about six sheets for each specimen; to change the paper at intervals of six to twelve hours; to avoid contact of one leaf or flower with another; and to increase the pressure applied only in proportion to the dryness of the specimen. To preserve the colour of flowers pledgets of cotton wool, which prevent bruising, should be introduced between them, as also, if the stamens are thick and succulent, as in *Digitalis*, between these and the corolla. A flower dissected and gummed on the sheets will often retain the colour which it is impossible to preserve in a crowded inflorescence. Before placing in a screw-press, should that be used, a flat sheet of lead or some other suitable weight should be laid upon the top of the pile of specimens, so as to keep up a continuous pressure. Succulent specimens, as many of the *Orchidaceæ*, and sedums and various other Crassulaceous plants, require to be killed by immersion in boiling water before being placed in drying paper, or, instead of becoming dry, they will grow between the sheets. When, as with some plants like *Verbascum*, the thick hard stems are liable to cause the leaves to wrinkle in drying by removing the pressure from them, small pieces of bibulous paper or cotton wool may be placed upon the leaves near their point of attachment to the stem. When a number of specimens have to be submitted to pressure, ventilation is secured by means of frames corresponding in size to the drying paper, and composed of strips of wood or wires laid across each other so as to form a kind of network. Another mode of drying is to keep the specimens in a box of dry sand in a warm place for ten or twelve hours, and then press them in drying paper. A third method consists in placing the specimen within bibulous paper, and enclosing the whole between two plates of coarsely perforated zinc supported in a wooden frame. The zinc plates are then drawn close together by means of straps,

and suspended before a fire until the drying is effected. By the last two methods the colour of the flowers may be well preserved. When the leaves are finely divided, as in *Conium*, much trouble will be experienced in lifting a half-dried specimen from one paper to another; but the plant may be placed in a sheet of thin blotting paper, and the sheet containing the plant, instead of the plant itself, can then be moved. Thin straw-coloured paper, such as is used for biscuit bags, may be conveniently employed by travellers unable to carry a quantity of bibulous paper. It offers the advantage of fitting closely to thick-stemmed specimens, and of rapidly drying. A light but strong portonno, to which pressure by means of straps can be applied, and a few quires of this paper, if the paper be changed night and morning, will be usually sufficient to dry all except very succulent plants. When a specimen is too large for one sheet, and it is necessary, in order to show its habit, &c., to dry the whole of it, it may be divided into two or three portions, and each placed on a separate sheet for drying. Specimens may be judged to be dry when they no longer cause a cold sensation when applied to the cheek, or assume a rigidity not evident in the earlier stages of preparation.

Each class of flowerless or cryptogamic plants requires special treatment for the herbarium.

Marine algae are usually mounted on tough smooth white cartridge paper in the following manner. Growing specimens of good colour and in fruit are if possible selected, and cleansed as much as practicable from adhering foreign particles, either in the sea or a rocky pool. Some species rapidly change colour, and cause the decay of any others with which they come in contact. This is especially the case with the *Ectocarpi*, *Desmarestiæ*, and a few others, which should therefore be brought home in a separate vessel. In mounting, the specimen is floated out in a flat white dish containing sea-water, so that foreign matter may be detected, and a piece of paper of suitable size is placed under it, supported either by the fingers of the left hand or by a palette. It is then pruned, in order clearly to show the mode of branching, and is spread out as naturally as possible with the right hand. For this purpose a bone knitting-needle answers well for the coarse species, and a camel's-hair pencil for the more delicate ones. The paper with the specimen is then carefully removed from the water by sliding it over the edge of the dish so as to drain it as much as possible. If during this process part of the fronds run together, the beauty of the specimen may be restored by dipping the edge into water, so as to float out the part and allow it to subside naturally on the paper. The paper, with the specimen upwards, is then laid on bibulous paper for a few minutes to absorb as much as possible of the superfluous moisture. When freed from excess of water it is laid on a sheet of thick white blotting-paper, and a piece of smooth washed calico is placed upon it (unwashed calico, on account of its "facing," adheres to the sea-weed). Another sheet of blotting-paper is then laid over it; and, a number of similar specimens being formed into a pile, the whole is submitted to pressure, the paper being changed every hour or two at first. The pressure is increased, and the papers are changed less frequently as the specimens become dry, which usually takes place in thirty-six hours. Some species, especially those of a thick or leathery texture, contract so much in drying that without strong pressure the edges of the paper become puckered. Other species of a gelatinous nature, like *Acetabulum* and *Dilobocladia*, may be allowed to dry on the paper, and need not be submitted to pressure until they no longer present a gelatinous appearance. Large coarse algae, such, for instance, as the *Fucales* and *Laminaria*, do not readily adhere to paper, and require soaking for some time in fresh water before being pressed. The less robust species, such as *Cladophora scoparia*, which do not adhere well to paper, may be made to do so by brushing them over either with milk carefully skimmed, or with a liquid formed by placing isinglass (1 oz.) and water (1½ oz.) in a wide-mouthed bottle, and the bottle in a small glass tinned saucepan containing cold water, heating until solution is effected, and then adding 1 oz. of rectified spirits of wine; the whole is next stirred together, and when cold is kept in a stoppered bottle. For use, the mixture is warmed to render it fluid, and applied by means of a camel's-hair brush to the under side of the specimen, which is then laid neatly on paper. For the more delicate species, such as the *Callithamnion* and *Ectocarpi*, it is an excellent plan to place a small fruiting fragment, carefully floated out in water, on a slip of mica of the size of an ordinary microscopical slide, and allow it to dry. The plant can then be at any time examined under the microscope without injuring the mounted specimen. Many of the fresh-water algae which form a mere crust, such as *Palmella cruenta*, may be placed in a vessel of water, where after a time they float like a scum, the earthy matter settling down to the bottom, and may then be mounted by slipping a piece of mica under them and allowing it to dry. *Oscillatoria* may be mounted by laying a portion on a silver coin placed on a piece of paper in a plate, and pouring in water until the edge of the coin is just covered. The alga by its own peculiar movement will soon form a radiating circle, perfectly free from dirt, around the coin, which may then be removed.

There is considerable difficulty in removing mounted specimens of algae from paper, and therefore a small portion preserved on mica should accompany each specimen, enclosed for safety in a small envelope fastened at one corner of the sheet of paper. Filamentous diatoms may be mounted like ordinary seaweeds, and, as well as all parasitic algae, should whenever possible be allowed to remain attached to a portion of the alga on which they grow, some species being almost always found parasitical on particular plants. Ordinary diatoms and desmids may be mounted on mica, as above described, by putting a portion in a vessel of water and exposing it to sunlight, when they rise to the surface, and may be thus removed comparatively free from dirt or impurity. Owing to their want of adhesiveness, they are, however, usually mounted on glass as microscopic slides, either in glycerin jelly, Canada balsam, or some other suitable medium.

Lichens are generally mounted on sheets of paper of the ordinary size, several specimens from different localities being laid upon one sheet, each specimen having been first placed on a small square of paper which is gummed on the sheet, and which has the locality, date, name of collector, &c., written upon it. This mode has some disadvantages attending it: such sheets are difficult to handle; the crustaceous species are liable to have their surfaces rubbed; the foliaceous species become so compressed as to lose their characteristic appearance; and the spaces between the sheets caused by the thickness of the specimen permit the entrance of dust. A plan which has been found to answer well is to arrange them in cardboard boxes, either with glass tops or in sliding covers, in drawers—the name being placed outside each box, and the specimens gummed into the boxes. Lichens for the herbarium should, whenever possible, be sought for on a slaty or laminated rock, so as to procure them on flat thin pieces of the same, suitable for mounting. Specimens on the bark of trees require pressure until the bark is dry, lest they become curled; and those growing on sand or friable soil, such as *Coniocybe furfuracea*, should be laid carefully on a layer of gum in the box in which they are intended to be kept. Many lichens, such as the *Verrucariæ* and *Collema*, are found in the best condition during the winter months. In mounting *Collema* it is advisable to let the specimen become dry and hard, and then to separate a portion from adherent mosses, earth, &c., and mount it separately so as to show the branching of the thallus. *Pertusaria* should be represented by both fruiting and sorediate specimens.

The larger species of fungi, such as the *Agaricini* and *Polypori*, &c., are prepared for the herbarium by cutting a slice out of the centre of the plant so as to show the outline of the pileus, the attachment of the gills, and the character of the interior of the stem. The remaining two halves of the pileus are then lightly pressed, as well as the central slices, between bibulous paper until dry, and the whole is then "poisoned," and gummed on a sheet of paper in such a manner as to show the under surface of the one and the upper surface of the other half of the pileus on the same sheet. As it is impossible to preserve the natural colours of fungi, the specimens should, whenever possible, be accompanied by a coloured drawing of the plant. Microscopic fungi are usually preserved in envelopes, or simply attached to sheets of paper, or mounted as microscopic slides. Those fungi which are of a dusty nature, like the *Myzomycetes*, may, like the lichens, be preserved in small boxes, and arranged in drawers. Fungi under any circumstances form the least satisfactory portion of an herbarium.

Mosses when growing in tufts should be gathered just before the capsules have become brown, divided into small flat portions, and pressed lightly in drying paper. During this process the capsules ripen, and are thus obtained in a perfect state. They are then preserved in envelopes attached to a sheet of paper of the ordinary size, a single perfect specimen being washed, and spread out near the envelope so as to show the habit of the plant. For attaching it to the paper a strong mucilage of gum tragacanth, containing an eighth of its weight of spirit of wine, answers best. If not preserved in an envelope the calyx and operculum are very apt to fall off and become lost. Scale-mosses are mounted in the same way, or may be floated out in water like sea-weeds, and dried in white blotting paper under strong pressure before gumming on paper, but are best mounted as microscopic slides, care being taken to show the stipules. The specimens should be collected when the capsules are just appearing above or in the colesule or calyx; if kept in a damp saucer they soon arrive at maturity, and can then be mounted in better condition, the fruit-stalks being too fragile to bear carriage in a botanical tin case without injury.

Of the *Characeæ* many are so exceedingly brittle that it is best to float them out like sea-weeds, except the prickly species, which may be carefully laid out on bibulous paper, and when dry fastened on sheets of white paper by means of gummed strips. Care should be taken in collecting chara to secure, in the case of dioecious species, specimens of both forms, and also to get when possible the roots of these species on which the small granular starchy bodies or gemmæ are found, as in *C. fragifera*. Portions of the fructification may be preserved in small envelopes attached to the sheets.

See Bentham, *Proc. Linn. Soc. Lond.*, 1869-70, p. xlvi.; Johann Nave, *Handy Book to the Collection and Preparation of Freshwater and Marine Alga*, &c., Lond.; G. Rainann, *Das Herbarium*, Berlin; and Lasègue's *Musée botanique de M. Benjamin Delessert*, Paris, 1845. (E. M. H.)

HERBART, JOHANN FRIEDRICH (1776-1841), was born of cultured parents at Oldenburg in 1776. He showed his bent towards philosophy while still a child, and after studying under Fichte at Jena gave his first philosophical lectures at Göttingen in 1805, whence he removed in 1809 to occupy the chair formerly held by Kant at Königsberg. Here he also established and conducted a seminary of pedagogy till 1833, when he returned once more to Göttingen, and remained there as professor of philosophy till his death in 1841. His works were collected and published in twelve volumes by his disciple Hartenstein (Leipsic, 1850-52).

Philosophy, according to Herbart, begins with reflexion upon our empirical conceptions, and consists in the reformation and elaboration of these,—its three primary divisions being determined by as many distinct forms of elaboration. Logic, which stands first, has to render our conceptions and the judgments and reasonings arising from them clear and distinct. But some conceptions are such that the more distinct they are made the more contradictory their elements become; so to change and supplement these as to make them at length thinkable is the problem of the second part of philosophy, or Metaphysics. There is still a class of conceptions requiring more than a logical treatment, but differing from the last in not involving latent contradictions, and in being independent of the reality of their objects, the conceptions, viz., that embody our judgments of approval and disapproval; the philosophic treatment of these conceptions falls to Æsthetic.

In Herbart's writings logic receives comparatively meagre notice; he insisted strongly on its purely formal character, and expressed himself in the main at one with Kantians such as Fries and Krug.

As a metaphysician he starts from what he terms "the higher scepticism" of the Hume-Kantian sphere of thought, the beginnings of which he discerns in Locke's perplexity about the idea of substance. By this scepticism the real validity of even the forms of experience is called in question on account of the contradictions they are found to involve. And yet that these forms are "given" to us, as truly as sensations are, follows beyond doubt when we consider that we are as little able to control the one as the other. To attempt at this stage a psychological inquiry into the origin of these conceptions would be doubly a mistake; for we should have to use these illegitimated conceptions in the course of it, and the task of clearing up their contradictions would still remain, whether we succeeded in our inquiry or not. But how are we to set about this task? We have given to us a conception A uniting among its constituent marks two that prove to be contradictory, say M and N; and we can neither deny the unity nor reject one of the contradictory members. For to do either is forbidden by experience; and yet to do nothing is forbidden by logic. We are thus driven to the assumption that the conception is contradictory because incomplete; but how are we to supplement it? What we have must point the way to what we want, or our procedure will be arbitrary. Experience asserts that M is the same (*i.e.*, a mark of the same concept) as N, while logic denies it; and so—it being impossible for one and the same M to sustain these contradictory positions—there is but one way open to us; we must posit several Ms. But even now we cannot say one of these Ms is the same as N, another is not; for every M must be both thinkable and valid. We may, however, take the Ms. not singly but together; and again, no other course being open to us, this is what we must do; we must assume that N results from a combination of Ms. This is Herbart's method of relations, the counterpart in his system of the Hegelian dialectic.

In the *Ontology* this method is employed to determine what in reality corresponds to the empirical conceptions of substance and cause, or rather of inherence and change. But first we must analyse this notion of reality itself, to which our scepticism had already led us, for, though we could doubt whether "the given" is what it appears, we cannot doubt that it is something; the conception of the real thus consists of the two conceptions of being and quality. That which we are compelled to "posit," which cannot be sublated, is that which is, and in the recognition of this lies the simple conception of being. But when is a thing thus posited? When it is posited as we are wont to posit the things we see and taste and handle. If we were without sensations, *i.e.*, were never bound against our will to endure the persistence of a presentation, we should never know what being is. Keeping fast hold of this idea of absolute position, Herbart leads us next to the quality of the real. (1) This must exclude everything negative; for non-A sublates instead of positing, and is not absolute, but relative to A. (2) The real must be absolutely simple; for if it contain two deter-

minations, A and B, then either these are reducible to one, which is the true quality, or they are not, when each is conditioned by the other and their position is no longer absolute. (3) All quantitative conceptions are excluded, for quantity implies parts, and these are incompatible with simplicity. (4) But there may be a plurality of "reals," albeit the mere conception of being can tell us nothing as to this. The doctrine here developed is the first cardinal point of Herbart's system, and has obtained for it the name of "pluralistic realism."

The contradictions he finds in the common-sense conception of inherence, or of "a thing with several attributes," will now become obvious. Let us take some thing, say A, having n attributes, a, b, c, \dots ; we are forced to posit each of these because each is presented in intuition. But in conceiving A we make, not n positions, still less $n+1$ positions, but one position simply; for common sense removes the absolute position from its original source, sensation. So when we ask, What is the one posited? we are told—the possessor of a, b, c, \dots , or in other words, their seat or substance. But if so, then A, as a real, being simple, must $= a$; similarly it must $= b$; and so on. Now this would be possible if a, b, c, \dots were but "contingent aspects" of A, as *c.g.*, $2^3, \sqrt{64}, 4+3+1$ are contingent aspects of 8. Such, of course, is not the case, and so we have as many contradictions as there are attributes; for we must say A is a , is not a , is b , is not b , &c. There must then, according to the method of relations, be several As. For a let us assume $A_1 + A_1 + A_1, \dots$; for b , $A_2 + A_2 + A_2, \dots$; and so on for the rest. But now what relation can there be among these several As, which will restore to us the unity of our original A or substance? There is but one; we must assume that the first A of every series is identical, just as the centre is the same point in every radius. By way of concrete illustration Herbart instances "the common observation that the properties of things exist only under external conditions. Bodies, we say, are coloured, but colour is nothing without light, and nothing without eyes. They sound, but only in a vibrating medium, and for healthy ears. Colour and tone present the appearance of inherence, but on looking closer we find they are not really immanent in things but rather presuppose a communion among several." The result then is briefly thus:—In place of the one absolute position, which in some unthinkable way the common understanding substitutes for the absolute positions of the n attributes, we have really a series of two or more positions for each attribute, every series, however, beginning with the same (as it were, central) real (hence the unity of substance in a group of attributes), but each being continued by different reals (hence the plurality and difference of attributes in unity of substance). Where there is the appearance of inherence, therefore, there is always a plurality of reals; no such correlative to substance as attribute or accident can be admitted at all. Substantiality is impossible without causality, and to this as its true correlative we now turn.

The common-sense conception of change involves at bottom the same contradiction of opposing qualities in one real. The same A that was a, b, c, \dots becomes a, b, d, \dots ; and this, which experience thrusts upon us, proves on reflexion unthinkable. The metaphysical supplementing is also fundamentally as before. Since c depended on a series of reals $A_3 + A_3 + A_3, \dots$ in connexion with A, and d may be said similarly to depend on a series $A_4 + A_4 + A_4, \dots$, then the change from c to d means, not that the central real A or any real has changed, but that A is now in connexion with A_4 , &c., and no longer in connexion with A_3 , &c.

But to think a number of reals "in connexion" (*Zusammensein*) will not suffice as an explanation of phenomena; something or other must happen when they are in connexion; what is it? The answer to this question is the second hinge-point of Herbart's theoretical philosophy. What "actually happens" as distinct from all that seems to happen, when two reals A and B are together is that, assuming them to differ in quality, they tend to disturb each other to the extent of that difference, at the same time that each preserves itself intact by resisting, as it were, the other's disturbance. And so by coming into connexion with different reals the "self-preservation" of A will vary accordingly, A remaining the same through all; just as, by way of illustration, hydrogen remains the same in water and in ammonia, or as the same line may be now a normal and now a tangent. But to indicate this opposition in the qualities of the reals A+B, we must substitute for these symbols others, which, though only "contingent aspects" of A and B, *i.e.*, representing their relations, not themselves, yet like similar devices in mathematics enable thought to advance. Thus we may put $A = \alpha + \beta - \gamma$, $B = m + n + \gamma$; γ then represents the character of the self-preservation in this case, and $\alpha + \beta + m + n$ represents all that could be observed by a spectator who did not know the simple qualities, but was himself involved in the relations of A to B; and such is exactly our position.

Having thus determined what really is and what actually happens, our philosopher proceeds next to explain synthetically the objective semblance (*der objective Schein*) that results from these. But if this construction is to be truly objective, *i.e.*, valid for all intelli-

gences, ontology must furnish us with a clue. This we have in the forms of Space, Time, and Motion which are involved whenever we think the reals as being in, or coming into, connexion, and the opposite. These forms then cannot be merely the products of our psychological mechanism, though they may turn out to coincide with these. Meanwhile let us call them "intelligible," as being valid for all who comprehend the real and actual by thought, although no such forms are predicable of the real and actual themselves. The elementary spatial relation Herbart conceives to be "the contiguity (*Aneinander*) of two points," so that every "pure and independent line" is discrete. But an investigation of dependent lines which are often incommensurable forces us to admit the contradictory fiction of partially overlapping, *i.e.*, divisible points, or in other words, the conception of Continuity.¹ But the contradiction here is one we cannot eliminate by the method of relations, because it does not involve anything real; and in fact as a necessary outcome of an "intelligible" form, the fiction of continuity is valid for the "objective semblance," and no more to be discarded than say $\sqrt{-1}$. By its help we are enabled to comprehend what actually happens among reals to produce the appearance of matter. When three or more reals are together, each disturbance and self-preservation will (in general) be imperfect, *i.e.*, of less intensity than when only two reals are together. But "objective semblance" corresponds with reality; the spatial or external relations of the reals in this case must, therefore, tally with their inner or actual states. Had the self-pervations been perfect, the coincidence in space would have been complete, and the group of reals would have been inextended; or had the several reals been simply contiguous, *i.e.*, without connexion, then, as nothing would actually have happened, nothing would appear. As it is we shall find a continuous molecule manifesting attractive and repulsive forces; attraction corresponding to the tendency of the self-pervations to become perfect, repulsion to the frustration of this. Motion, even more evidently than space, implicates the contradictory conception of continuity, and cannot, therefore, be a real predicate, though valid as an intelligible form and necessary to the comprehension of the objective semblance. For we have to think of the reals as absolutely independent and yet as entering into connexions. This we can only do by conceiving them as originally moving through intelligible space in rectilinear paths and with uniform velocities. For such motion no cause need be supposed; motion, in fact, is no more a state of the moving real than rest is, both alike being but relations, with which, therefore, the real has no concern. The changes in this motion, however, for which we *should* require a cause, would be the objective semblance of the self-pervations that actually occur when reals meet. Further, by means of such motion these actual occurrences, which are in themselves timeless, fall for an observer in a definite time—a time which becomes continuous through the partial coincidence of events.

But in all this it has been assumed that we are spectators of the objective semblance; it remains to make good this assumption, or, in other words, to show the possibility of knowledge; this is the problem of what Herbart terms Eidology, and forms the transition from metaphysic to psychology. Here, again, a contradictory conception blocks the way, that, *viz.*, of the Ego as the identity of knowing and being, and as such the stronghold of idealism. The contradiction becomes more evident when the ego is defined to be a subject (and so a real) that is its own object. As real and not merely formal, this conception of the ego is amenable to the method of relations. The solution this method furnishes is summarily that there are several objects which mutually modify each other, and so constitute that ego we take for the presented real. But to explain this modification is the business of psychology; it is enough now to see that the subject like all reals is necessarily unknown, and that, therefore, the idealist's theory of knowledge is unsound. But though the simple quality of the subject or soul is beyond knowledge, we know what actually happens when it is in connexion with other's reals, for its self-pervations then are what we call sensations. And these sensations are the sole material of our knowledge; but they are not given to us as a chaos but in definite groups and series, whence we come to know the relations of those reals, which, though themselves unknown, our sensations compel us to posit absolutely.

In his *Psychology* Herbart rejects altogether the doctrine of mental faculties as one refuted by his metaphysics, and tries to show that all psychical phenomena whatever result from the action and interaction of elementary ideas or presentations (*Vorstellungen*). The soul being one and simple, its separate acts of self-preservation or primary presentations must be simple too, and its several presentations must become united together. And this they can do at once and completely when, as is the case, for example, with the several attributes of an object, they are not of opposite quality. But otherwise there ensues a conflict in which the opposed presentations comport themselves like forces and mutually suppress or obscure each other. The act of presentation (*Vorstellen*) then

¹ Hence Herbart gives the name Synchology to this branch of metaphysics, instead of the usual one, Cosmology.

becomes partly transformed into an effort, and its product, the idea, becomes in the same proportion less and less intense till a position of equilibrium is reached; and then at length the remainders coalesce. We have thus a statics and a mechanics of mind which investigate respectively the conditions of equilibrium and of movement among presentations. In the statics two magnitudes have to be determined:—(1) the amount of the suppression or inhibition (*Hemmungssumme*), and (2) the ratio in which this is shared among the opposing presentations. The first must obviously be as small as possible: thus for two totally opposed presentations a and b , of which a is the greater, the *inhibendum* = b . For a given degree of opposition this burden will be shared between the conflicting presentations in the inverse ratio of their strength. When its remainder after inhibition = 0, a presentation is said to be on the threshold of consciousness, for on a small diminution of the inhibition the "effort" will become actual presentation in the same proportion. Such total exclusion from consciousness is, however, manifestly impossible with only two presentations,¹ though with three or a greater number the residual value of one may even be negative. The first and simplest law in psychological mechanics relates to the "sinking" of inhibited presentations. As the presentations yield to the pressure, the pressure itself diminishes, so that the velocity of sinking decreases, *i.e.*, we have the equation, $(S - \sigma) d^2 = d\sigma$, where S is the total *inhibendum*, and σ the intensity actually inhibited after the time t . Hence $t = \log \frac{S}{S - \sigma}$, and $\sigma = S(1 - e^{-t})$.

From this law it follows, for example, that equilibrium is never quite obtained for those presentations which continue above the threshold of consciousness, while the rest which cannot so continue are very speedily driven beyond the threshold. More important is the law according to which a presentation freed from inhibition and rising anew into consciousness tends to raise the other presentations with which it is combined. Suppose two presentations p and π united by the residua r and ρ ; then the amount of p 's "help" to π is r , the portion of which appropriated by π is given by the ratio $\rho : \pi$; and thus the initial help $\approx \frac{r\rho}{\pi}$.

But after a time t , when a portion of ρ represented by ω has been actually brought into consciousness, the help afforded in the next instant will be found by the equation

$$\frac{r\rho}{\pi} \cdot \frac{\rho - \omega}{\rho} dt = d\omega,$$

from which by integration we have the value of ω ,

$$\omega = \rho \left(1 - e^{-\frac{rt}{\pi}} \right).$$

So that if there are several π s connected with p by smaller and smaller parts, there will be a definite "serial" order in which they will be revived by p : and on this fact Herbart rests all the phenomena of the so-called faculty of memory, the development of spatial and temporal forms, and much besides. Emotions and volitions, he holds, are not directly self-preservation of the soul, as our presentations are, but variable states of such presentations resulting from their interaction when above the threshold of consciousness. Thus when some presentations tend to force a presentation into consciousness, and others at the same time tend to drive it out, that presentation is the seat of painful feeling; when, on the other hand, its entrance is favoured by all, pleasure results. Desires are presentations struggling into consciousness against hindrances, and when accompanied by the supposition of success become volitions. Transcendental freedom of will in Kant's sense is an impossibility. Self-consciousness is the result of an interaction essentially the same in kind as that which takes place when a comparatively simple presentation finds the field of consciousness occupied by a long-formed and well-consolidated "mass" of presentations—as, *e.g.*, one's business or garden, the theatre, &c., which promptly inhibit the isolated presentation if incongruent, and unite it to themselves if not. What we call Self is, above all, such a central mass, and Herbart seeks to show with great ingenuity and detail how this position is occupied at first chiefly by the body, then by the seat of ideas and desires, and finally by that first-personal Self which recollects the past and resolves concerning the future. But at any stage the actual constituents of this "complexion" are variable; the concrete presentation of Self is never twice the same. And, therefore, finding on reflexion any particular concrete factor contingent, we abstract the position from that which occupies it, and so reach the speculative notion of the pure I-go.

Aesthetics elaborates the "ideas" involved in the expression of taste called forth by those relations of object which acquire for them the attribution of beauty or the reverse. The beautiful (*καλόν*) is

¹ Thus, taking the case above supposed, the share of the *inhibendum* falling to the smaller presentation b is the fourth term of the proportion $a + b : a :: b : \frac{ab}{a+b}$; and so b 's remainder is $b - \frac{ab}{a+b} = \frac{b^2}{a+b}$ which only = 0 when $a = \infty$.

to be carefully distinguished from the allied conceptions of the useful and the pleasant, which vary with time, place, and person; whereas beauty is predicated absolutely and involuntarily by all who have attained the right standpoint. Ethics, which is but one branch of aesthetics, although the chief, deals with such relations among volitions (*Willensverhältnisse*) as thus unconditionally please or displease. These relations Herbart finds to be reducible to five, which do not admit of further simplification; and corresponding to them are as many moral ideas (*Musterbegriffe*), *viz.*:—(1) *Internal Freedom*, the underlying relation being that of the individual's will to his judgment of it; (2) *Perfection*, the relation being that of his several volitions to each other in respect of intensity, variety, and concentration; (3) *Benevolence*, the relation being that between his own will and the thought of another's; (4) *Right*, in case of actual conflict with another; and (5) *Retribution or Equity*, for intended good or evil done. The ideas of a final society, a system of rewards and punishments, a system of administration, a system of culture, and a "unanimous society," corresponding to the ideas of law, equity, benevolence, perfection, and internal freedom respectively, result when we take account of a number of individuals. Virtue is the perfect conformity of the will with the moral ideas; of this the single virtues are but special expressions. The conception of duty arises from the existence of hindrances to the attainment of virtue. A general scheme of principles of conduct is possible, but the subsumption of special cases under these must remain matter of tact. The application of ethics to things as they are with a view to the realization of the moral ideas is moral technology (*Tugendlehre*), of which the chief divisions are Pædagogic and Politics.

In *Theology* Herbart held the argument from design to be as valid for divine activity as for human, and to justify the belief in a supersensible real, concerning which, however, exact knowledge is neither attainable nor on practical grounds desirable.

Among the post-Kantian philosophers Herbart doubtless ranks next to Hegel in importance, and this without taking into account his very great contributions to the science of education. His disciples speak of theirs as the "exact philosophy," and the term well expresses their master's chief excellence and the character of the chief influence he has exerted upon succeeding thinkers of his own and other schools. His criticisms are worth more than his constructions; indeed for exactness and penetration of thought he is quite on a level with Hume and Kant. His merits in this respect, however, can only be appraised by the study of his works at first hand. But we are most of all indebted to Herbart for the enormous advance psychology has been enabled to make, thanks to his fruitful treatment of it, albeit as yet but few among the many who have appropriated and improved his materials have ventured to adopt his metaphysical and mathematical foundations. (J. W.*)

HERBELOT, BARTHÉLEMY D' (1625-1695), Orientalist, was born December 4, 1625, at Paris. As soon as he had completed the ordinary course in classics and philosophy at the university of his native city, he devoted himself to the study of the Oriental languages, and went to Italy to perfect himself in them by converse with the Orientals who frequented its seaports. There he made the acquaintance of his fellow-savants Lucas Holstenius and Leo Allatius, and attracted the favourable notice of the cardinals Grimaldi and Bamberini. On his return to France after a year and a half, he was received into the house of Fouquet, superintendent of finance, who gave him a pension of 1500 livres. Losing this on the disgrace of Fouquet in 1661, he was appointed secretary and interpreter of Eastern languages to the king. A few years later he again visited Italy, when the grand-duke Ferdinand II. of Tuscany presented him with a large number of valuable Oriental MSS., and tried to attach him to his court. Herbelot, however, was recalled to France by Colbert, and received from the king a pension equal to the one he had lost. In 1692 he succeeded D'Auvergne in the chair of Syriac, in the Collège de France. He died at Paris, December 8, 1695. His great work is the *Bibliothèque Orientale, ou dictionnaire universel contenant tout ce qui fait connaître les peuples de l'Orient*, which occupied him nearly all his life, and was published in 1697 by Galland. It is based on the immense Arabic dictionary of Hajji Khalfa, of which indeed it is largely an abridged translation, but it also contains the substance of a vast number of other Arabic and Turkish compilations and manuscripts. With all his learning, the author seems to have been deficient in critical

sagacity, and there is consequently a want of minute accuracy in many of its details, and of harmony between its various parts. It is, however, even yet the one available source for much information to others than Oriental scholars, and as such it retains its importance.

The *Bibliothèque* has been reprinted at Maestricht (fol. 1776), and at the Hague (4 vols. 4to, 1777-99). The latter edition is enriched with the contributions of Schultens, Reiske, and others. Herbelot's other works, none of which have been published, comprise an *Oriental Anthology*, and an *Arabic, Persian, Turkish, and Latin Dictionary*.

HERBERT, GEORGE (1593-1633), one of the best of English religious poets, was born near the town of Montgomery on the 3d of April 1593. He was a brother of Lord Herbert of Cheshire, noticed below. Educated privately till the age of twelve, he was then sent to Westminster School, and in 1608 he became a student at Trinity College, Cambridge, where he was made B.A. in 1611, M.A. and major fellow of the college in 1615, and orator for the university in 1619. In his capacity as orator he was several times brought into contact with King James. About the same time also he appeared as the champion of Anglicanism against Andrew Melville, the famous Scotch Presbyterian. He numbered among his friends Dr Donne, Sir Henry Wotton, Izaak Walton, Bishop Andrewes, and Francis Bacon, who consulted Herbert about several of his works, and dedicated to him his translation of the Psalms. During his youth he was a courtier, dancing attendance on King James, and "enjoying his genteel humour for clothes"; and the king rewarded his attentions by the gift of a sinecure worth £120 a year. The death of his patrons the duke of Richmond, the marquis of Hamilton, and King James, approaching ill-health, and the influence of his mother finally induced him, not without a struggle, to take holy orders. In July 1626 he was appointed prebendary of Layton Ecclesia, in the county of Huntingdon. Shortly before his induction (1630) to the parsonage of Bemerton, near Salisbury, he married Miss Jane Danvers after three days' acquaintance. Mr Danvers had been set on the marriage for a long time, and had often spoken of his daughter Jane to Herbert, and "so much commended Mr Herbert to her, that Jane became so much a Platonic as to fall in love with Mr Herbert unseen." The story of the poet's life at Bemerton, as told by Walton, is one of the most exquisite pictures in literary biography. He devoted much time to explaining the meaning of the various parts of the Prayer-Book, and held services twice every day, at which many of the parishioners attended, and some "let their plough rest when Mr Herbert's saints-bell rung to praise, that they might also offer their devotions to God with him." Next to Christianity itself he loved the English Church. He was passionately fond of music, and usually went twice a week to attend the cathedral service at Salisbury. Walton illustrates Herbert's kindness to the poor by many touching anecdotes. He had not been three years in Bemerton when he succumbed to ill-health. He died in 1633.

Herbert's works are—*The Temple* (1631); a few miscellaneous poems; a collection of proverbs entitled *Jacula Prudentum* (1640); and *The Country Parson*, which did not appear till 1652. *The Temple* is a collection of religious poems marked by unity of sentiment and inspiration. The chief faults of the book are obscurity, verbal conceits, and a forced ingenuity which shows itself in grotesque puns, odd metres, and occasional want of taste. In spite of these drawbacks, the quaint beauty of Herbert's style and his genuine poetical feeling give *The Temple* a high place in literature. The following poems are the gems of the collection:—"The Church Porch," "The Agency," "Sin," "Sunday," "Virtue," "Man," "The British Church," "The Quip," "The Collar," "The Pulley," "The Flower," "Aaron," and "The Elixir." The finest of all is his poem on "Man," which is Miltonic in its sublimity of conception, and shows how poets, in their loftier moods, often anticipate the discoveries of science and the most far-reaching speculations of philosophy. Herbert and Keble are the poets of Anglican

theology. No book is fuller of devotion to the Church of England than *The Temple*. No poem in our language exhibits more of the spirit of true Christianity. Every page is marked by transparent sincerity, and reflects the beautiful character of "holy George Herbert."

Among recent editions of Herbert's works the following may be mentioned:—*Works in Prose and Verse*, with life by Izaak Walton, and notes by S. T. Coleridge, 1846; Gilfillan's edition, in his "Library of the British Poets," 1853; Willmott's edition, 1854; Professor Nichol's edition, 1863; and the Aldine edition by the Rev. Dr A. B. Grosart. For further information consult Walton's *Life*, and *England's Antiphon*, by George Macdonald, 1871.

HERBERT, HENRY WILLIAM (1807-1858), novelist and writer on sports, son of the Hon. and Rev. William Herbert, dean of Manchester, a son of the first earl of Carnarvon, was born in London, April 7, 1807. He was educated at Eton and at Caius College, Cambridge, where he graduated M.A. in 1828. Having become involved in debt he emigrated to America, and from 1831 to 1839 was teacher of Greek in a private school in New York. In 1833 he commenced the *American Monthly Magazine*, which he edited till 1835. In 1834 he published his first novel, *The Brothers, a Tale of the Fronde*, which was followed by a number of others, all of them obtaining a certain degree of popularity. He was also successful in a series of historical studies, such as *The Cavaliers of England*, *The Knights of England, France, and Scotland*, *The Chevaliers of France*, and *The Captains of the Old World*, and wrote numerous contributions to magazines; but he is best known for his works on sporting, published by him under the pseudonym of Frank Forester. These include *The Field Sports of the United States and British Provinces* (1849), *Frank Forester and his Friends* (1849), *The Fish and Fishing of the United States* (1850), *The Young Sportsman's Complete Manual*, and *The Horse and Horsemanship in the United States and British Provinces of North America* (1858). Herbert was a man of varied accomplishments, but of somewhat dissipated habits. He died by his own hand at New York, May 17, 1858.

HERBERT, SIR THOMAS (1606-1682), traveller and author, was born at York in 1606. Several of his ancestors were aldermen and merchants in that city, and they could trace their connexion with the great Herbert family represented by the earl of Pembroke. His grandfather, Alderman Herbert, who died in 1614, left him real estate of considerable value. He went to Oxford in 1621, and became a commoner of Jesus College, but afterwards removed to Cambridge at the invitation of his mother's brother, Dr Ambrose Akroyd. Having gone to London, he was introduced to the earl of Pembroke, through whose influence he obtained an appointment in the suite of Sir Dodmore Cotton, who was about to leave as ambassador for Persia in company with Sir Robert Shirley. Sailing in March 1627, they visited the Cape, Madagascar, Goa, and Srnat; having landed at Gombroon, they travelled inland to Asharoff, and thence to Cazbeen, where both the chiefs of the expedition died. Herbert reached England again in 1629, and in 1630, to his great disappointment, his patron the earl of Pembroke died suddenly. After this he travelled on the Continent for more than a year. From his return in 1631 till about two years after his marriage in 1632 he retained his ambition for court favour, but failing in this he retired, probably to his estate of Tintern in Monmouthshire, till the outbreak of the civil war, when he sided with the parliament. In 1646 he was appointed to attend the king with his other servants. Becoming a devoted royalist, he continued with his majesty during the last two eventful years of his life, and at the Restoration he was rewarded with the title of baronet (1660). He resided at Westminster till the great plague, when he returned to York and bought Petergate House, where he died on the 1st March 1682.

It was in 1624 that Herbert first published his *Description of the Persian Monarchy now being: the Orientall Indyes, Iles and other parts of the Greater Asia and Africk*. Four years later a new and enlarged edition appeared under the title of *Some Yeares Travels into Africa and Asia the Great*; a third edition followed in 1664, and a fourth in 1677. The work is evidently the production of a man of considerable scholarship and activity of mind, and altogether ranks as one of the best records of 17th century travel. It is illustrated with woodcuts, among which the sketch of the dodo, the specimen of the cuneiform inscriptions, and the view of Persepolis deserve to be mentioned. Herbert's *Threnodia Carolina, or Memoirs of the two last years of the reign of that unparalleled prince of ever blessed memory King Charles I.*, was in great part printed at the author's request in Wood's *Athenæ Oxonienses*, but it did not appear in its entirety till Dr Charles Goodall published his Collection of Tracts in 1702. A reprint was issued by G. and W. Nicol in 1813. Sir William Dugdale is understood to have received assistance from Herbert in preparing the fourth volume of the *Monasticon Anglicanum*; and Mr Drake has printed in the appendix to his *Eboracum* two papers from Herbert's pen on the church of St John at Beverley and the collegiate church of Ripon. The best account of Sir Thomas Herbert is that by Robert Davies, F.S.A., York, which appeared in *The Yorkshire Archaeological and Topographical Journal*, part iii., pp. 182-214 (1870). It contains a facsimile of the long inscription on Herbert's tomb.

HERBERT, LORD, OF CHERBURY (1582-1648). Edward Herbert, Lord Herbert of Cherbury, soldier, diplomatist, historian, and religious philosopher, was born at Eyton in Shropshire in 1582, and was descended from an ancient line of illustrious soldiers, to which the earls of Pembroke belonged. Sent to Oxford in his twelfth year, he married an heiress, his kinswoman, in his fifteenth, and returned to the university to prosecute his "beloved studies." He was knighted soon after the accession of James I., and for a year or two fulfilled the functions of sheriff of his county. In 1608 he went abroad, at Paris gaining the esteem and love of the old Constable de Montmorency, and beginning an acquaintance with scholars like Casaubon, Gassendi, and Grotius. Next year he served as a volunteer in the Low Countries under the prince of Orange, whose intimate friend he became, and also took part in the campaigns of 1614 and 1615. Between the latter campaigns he visited Italy, and on his return was arrested in France for recruiting Huguenots for the service of the duke of Savoy. In 1618 he was sent as ambassador extraordinary to the court of France; and, though recalled for a few months through the hostility of the French king's favourite, he soon returned to Paris as ordinary ambassador. In 1625 he came back to England, where, with the exception of one or more short visits to Paris, he spent the rest of his life. Created Lord Herbert of Castle Island in 1625, he was raised by Charles I. to the English peerage in 1631 as Baron Herbert of Cherbury. In the civil war he sided at first with the court, and subsequently declared for the parliament, but the part he played was not a prominent one. His castle of Montgomery was, however, destroyed during the war, and he received an indemnity for his loss from the parliament. He died 20th August 1648.

"It is impossible to draw his picture well who hath several countenances," Herbert says of Henry VIII.; Horace Walpole made a bold attempt to sketch Herbert's character by declaring that in his case "the history of Don Quixote was the life of Plato." To his contemporaries Herbert was mainly known as a high-spirited man of the world, of great knightly and courtier-like accomplishments, who, though stiff and stately, was on the smallest actual provocation ready and able to defend his honour with his sword. He maintained the character of ambassador with dignity, but his diplomacy was not attended by much success. It is as author that Herbert is chiefly remembered. And though in 1633 the *De Veritate* received the official imprimatur of the bishop of London's chaplain, on the strength of the same work the writer was soon after held up to abhorrence as an atheist. As a resolute opponent of

empiricism in philosophy, he is unquestionably entitled to rank as one of the heralds of the philosophy of Reid and the Scottish metaphysicians. In the theological sphere he is justly claimed as the father of English deism, and doubtless exercised a strong influence on the religious thought of England. His views were not so novel as he thought them to be, but he was an original and very independent thinker; and, as his chief work was published but a few years after the *Novum Organum*, and many years before any of the works of Descartes or Hobbes, Herbert deserves a marked place in the van of modern speculation.

Herbert's first and most important work is the *De Veritate prout distinguitur a Revelatione, a Verisimilitudine, a Possibilitate, et a Falso* (Paris, 1624; translated into French, but never into English). It combines a theory of knowledge with a partial psychology, a methodology for the investigation of truth, and a scheme of natural religion. The author's method is prolix and often far from clear; the book is no compact system, but it contains the skeleton and much of the soul of a complete philosophy. Giving up all past philosophizings as useless, Herbert professedly endeavours to constitute a new and true system. Truth, which he defines as a just conformation of the faculties with one another and with their objects, he distributed into four classes or stages:—(1) truth in the thing or the truth of the object; (2) truth of the appearance; (3) truth of the apprehension (*conceptus*); (4) truth of the intellect. The faculties of the mind are as numerous as the differences of their objects, and are accordingly innumerable; but they may be arranged in four groups. The first and fundamental and most certain group is the *Natural Instinct*, to which belong the *κοινὰ ἔννοιαι*, the *Notitiæ Communes*, which are the "received principles of demonstration," existing in every sane and sound man, against which it is *nefas* to dispute. The second group, the next in certainty, is the *Sensus Internus* (under which head Herbert discusses amongst others love, hate, fear, conscience with its *communis notitia*, and free will); the third is the *Sensus Externus*; and the fourth is *Discursus*, reasoning, to which, as being the least certain, we have recourse when the other faculties fail. The ratiocinative faculties proceed by division and analysis; by questioning, and are slow and gradual in their movement; they take aid from the other faculties, those of the *instinctus naturalis* being always the final test. Herbert's categories or questions to be used in investigation are ten in number,—whether (a thing is), what, of what sort, how much, in what relation,—how, when, where, whence, wherefore. No faculty, rightly used, can err "even in dreams"; badly exercised, reasoning becomes the source of almost all our errors. The discussion of the *notitiæ communes* is the most characteristic part of the book. The exposition of them, though highly dogmatic, is at times strikingly Kantian in substance. "So far are these elements or sacred principles from being derived from experience or observation that without some of them, or at least some one of them, we can neither experience nor even observe." Unless we felt driven by them to explore the nature of things, "it would never occur to us to distinguish one thing from another." It cannot be said that Herbert proves the existence of the common notions; he does not deduce them or even give any list of them. But each faculty has its common notion; and they may be distinguished by six marks, their *priority, independence, universality, certainty, necessity* (for the well-being of man), and *immediacy*. Law is based on certain common notions; so is religion. Though Herbert expressly defines the scope of his book as dealing with the intellect, not faith, it is the common notions of religion he has illustrated most fully; and it is plain that it is in this part of his system that he is chiefly interested. The common notions of religion are the famous five articles, which became the charter of the English deists:—(1) that there is a supreme god; (2) that he ought to be worshipped; (3) that virtue and piety form the chief part of that worship; (4) that sins should be repented of; (5) that there are rewards and punishments in another life. To these doctrines, which constitute the faith of the true catholic and orthodox church, it is not easy to add anything that can make men more virtuous or godly. There is little polemic against the received form of Christianity, but Herbert's attitude towards the church's doctrine is distinctly negative, though he admits the possibility, under certain conditions, of specific and supernatural revelation. In the *De Religione Gentilium* (Lond., 1645) he gives what may be called, in Hume's words, "a natural history of religion." By examining the heathen religions Herbert finds, to his great delight, that under all their absurdities the five great articles were recognized. The heathen, yearning for the supreme God, saw Him in His works and worshipped Him in the most glorious of His creatures, the heavenly bodies. It was crafty priests who insisted on the necessity of multifarious rites and ceremonies, and developed full-fledged polytheism. The same vein is maintained in the tracts *De Causis Errorum* and *De Religione Laici*. Herbert's first historical work is the *Expeditio Buckinghami Ducis* (1656), an account

of Buckingham's ill-fated expedition in 1627. *The Life and Reign of King Henry VIII.* (1649), in pithy English, is called by Walpole "a masterpiece of historic biography," but is ill-proportioned and is digested into annals. It abounds in picturesque but prolix accounts of sieges and pageants at home and abroad; the sketch of the Reformation history is so dispassionate as to suggest a lack of keen sympathy with either party. Henry's character is very leniently judged. *The Life of Herbert by Himself* (first published by Horace Walpole in 1764) gives a vivacious and interesting account of his early life down to the return from his embassy, dwelling mainly, with something of an old man's garrulity and a famous man's vanity, on the romantic and chivalrous incidents in his career. Herbert's poems, Latin and English, are of small value.

There are sketches of Herbert in Leland's *Dristical Writers*, Lechler's *Geschichte des Englischen Deismus*, and elsewhere; but the only adequate work is M. Charles de Rémusat's *Lord Herbert de Cherbury, sa Vie et ses Œuvres* (Paris, 1874).

HERCULANEUM. The ruins of the buried city of Herculaneum are situated about two-thirds of a mile from the Portici station of the railway from Naples to Pompeii. They are less frequently visited than the ruins of the latter city, not only because they are smaller in extent and of less obvious interest, but also because they are more difficult of access. The history of their discovery and exploration, and the artistic and literary relics which they have yielded, are worthy, however, of particular notice. The small part of the city which has been restored to the light of day in the spot called *Gli scavi nuovi* (the new excavations) was discovered in the present century. But the more important works were executed in the last century; and of the buildings then explored at a great depth, by means of tunnels, none are visible except the theatre, the orchestra of which lies 85 feet below the surface of the soil.

The brief notices of the classical writers inform us that Herculaneum¹ was a small city of Campania between Neapolis and Pompeii, that it was situated between two streams at the foot of Vesuvius on a hill overlooking the sea, and that its harbour was at all seasons safe. With regard to its earlier history nothing is known. The account given by Dionysius repeats a tradition which was most natural for a city bearing the name of Hercules. Strabo follows up the topographical data with a few brief historical statements—"Ὅσσοι εἶχον καὶ ταύτην καὶ τὴν ἐφεξῆς Πομπηίαν . . . εἶτα Τυρρῆνοί καὶ Πελασγοί, μετὰ ταῦτα Σαννίται. But leaving the questions suggested by these names, such as that of the domination of the Etruscans in Campania,² as well as the other questions recently discussed in regard to the origin of Pompeii, which might have an intimate relation with our subject, it is sufficient here to say that the first historical record about Herculaneum has been handed down by Livy (viii. 25), where he relates in what manner the city fell under the power of Rome during the Samnite wars. It remained faithful to Rome for a long time, but it joined the Italian allies in the Social War. Having submitted anew in June of the year 665 (88 B.C.), it appears to have been less severely treated than Pompeii, and to have escaped the imposition of a colony of Sulla's veterans, although Zumpt has suspected the contrary

¹ A fragment of L. Sisenna calls it "Oppidum tumulo in excelso loco propter mare, parvis montibus, inter duas fluvias, infra Vesuvium collocatum" (lib. iv., fragm. 63, Peters). Of one of these rivers this historian again makes mention in the passage where probably he related the capture of Herculaneum by Minatius Magius and T. Didius (Velleius Paterculus, ii. 16). Further topographical details are supplied by Strabo, who, after speaking about Naples, continues—*ἐχόμενον δὲ φρούριόν ἐστιν Ἡράκλειον ἐκκειμένον εἰς τὴν θάλατταν ἔκραν ἔχον, καταπεσμένον λιβὴ θανατώσῃ ὡς ὄργισθην ποιεῖν τὴν κατοικίαν.* Dionysius of Halicarnassus relates that Hercules, in the place where he stopped with his fleet on the return voyage from Iberia, founded a little city (*πολίχνην*), to which he gave his own name; and he adds that this city was in his time inhabited by the Romans, and that, situated between Neapolis and Pompeii, it had *λιμένας ἐν παντὶ κατὰ τὸν Βεβαλῶν* (l. 44).

² Disputed by Niebuhr, *Hist. of Rome*, vol. i. p. 76, and by Mommsen, *Die Unteritalischen Dialekte*, 1850, p. 314.

(*Comm. Epigr.*, i. 259). It afterwards became a municipium, and enjoyed great prosperity towards the close of the republic and in the earlier times of the empire, since many noble families of Rome selected this pleasant spot for the construction of splendid villas, one of which indeed belonged to the imperial house (Seneca, *De Ira*, iii.). By means of the Via Campana it had easy communication north-westward with Neapolis, Putcoli, and Capua, and thence by the Via Appia with Rome; and southwards with Pompeii and Nuceria, and thence with Lucania and the Bruttii. In the year 63 A.D. it suffered terribly from the earthquake which, according to Seneca, "Campaiam nunquam securam hujus mali, indemnem tamen, et toties defunctam metu magna strage vastavit. Nam et Herculaneus oppidi pars ruit dubieque stant etiam quæ relicta sunt" (*Nat. Quæst.*, vi. 1). Hardly had Herculaneum completed the restoration of some of its principal buildings (*cf.* Mommsen, *I. N.*, n. 2384; *Catalogo del Museo Nazionale di Napoli*, n. 1151) when it fell beneath the great eruption of the year 79, described by Pliny the younger (*Ep.* vi. 16, 20), in which Pompeii also was destroyed with other flourishing cities of Campania. According to the commonest account, on the 23d August of that year Pliny the elder, who had command of the Roman fleet at Misenum, set out to render assistance to the soldiers stationed at Retina, near Herculaneum, as there was no escape except by sea, but, the little harbour having been on a sudden filled up so as to be inaccessible, he was obliged to abandon to their fate those people of Herculaneum and Retina who had managed to flee from their houses, overwhelmed in a moment by the material poured forth by Vesuvius. But the text of Pliny the younger, where this account is given, has been subjected to various interpretations; and from the comparison of other classical testimonies and the study of the excavations it has been concluded that it is impossible to determine the date of the catastrophe, though there are satisfactory arguments to justify the statement that the event took place in the autumn. The opinion that immediately after the first outbreak of Vesuvius a torrent of lava was ejected over Herculaneum was refuted by the scholars of the last century, and their refutation has been recently confirmed by Beulé (*L'Oratoire du Vésuve*, p. 240 sq.). And if the last recensions of the passage quoted from Pliny are to be accepted, Retina is not the name of the harbour described by Beulé (*ib.*, p. 122, 247), but the name of a lady who had implored succour, the wife of Cæsius Bassus, or rather Tascius (*cf.* Pliny, ed. Keil, Leipsic, 1870; Aulus Persius, ed. Jahn, *Sat.* vi.). The shore, moreover, according to the new and accurate studies of the engineer Michele Ruggiero, director of the excavations, was not altered by the causes adduced by Beulé (p. 125), but by a simpler event. "It is certain," he says (*Pompei e la Regione Sotterrata dal Vesuvio l'anno 79*, Naples, 1879, p. 21 sq.), "that the districts between the south and west, and those between the south and east, were overwhelmed in two quite different modes. From Torre Annunziata (which is believed to be the site of the ancient Oplontii) to San Giovanni a Teduccio, for a distance of about 9 miles, there flowed a muddy eruption which in Herculaneum and the neighbouring places, where it was most abundant, raised the level of the country more than 65 feet. The matter transported consisted of soil of various kinds,—sand, ashes, fragments of lava, pozzoiana, and whitish pumice, enclosing grains of uncalcined lime, similar in every respect to those of Pompeii. In the part of Herculaneum already excavated, the corridors in the upper portions of the theatre are compactly filled, up to the head of the arches, with pozzolana and pumice transformed into tuff (which proves that the formation of this stone may take place in a comparatively short time). Tuff is also

found in the lowest part of the city towards the sea in front of the few houses that have been discovered; and in the very high banks that surround them, as also in the lowest part of the theatre, there are plainly to be seen earth, sand, ashes, fragments of lava and pumice, with little distinction of strata, almost always confused and mingled together, and varying from spot to spot in degree of compactness. It is clear that this immense congeries of earth and stones could not flow in a dry state over those 5 miles of country (in the beginning very steep, and at intervals almost level), where certainly it would have been arrested and all accumulated in a mound; but it must have been borne along by a great quantity of water, the effects of which may be distinctly recognized, not only in the filling and choking up even of the most narrow, intricate, and remote parts of the buildings, but also in the formation of the tuff, in which water has so great a share; for it cannot be supposed that enough of it has filtered through so great a depth of earth. The torrent ran in a few hours to the sea, and formed that shallow or lagoon called by Pliny *Subitum Vadum*, which prevented the ships approaching the shores." Hence it is that, while many made their escape from Pompeii (which was overwhelmed by the fall of the small stones and afterwards by the rain of ashes), comparatively few can have managed to escape from Herculaneum, and these, according to the interpretation given to the inscription preserved in the National Museum (Mommson, *I. N.*, n. 2455), found shelter in the neighbouring city of Neapolis, where they inhabited a quarter called that of the buried city (Suetonius, *Titus*, 8). The name of Herculaneum, which for some time remained attached to the site of the disaster, is mentioned in the later itineraries; but in the course of the Middle Ages all recollection of it perished.

In 1709, while Prince Elbeuf of the house of Lorraine, in command of the armies of Charles VI., was seeking crushed marble to make plaster for his new villa near Portici, he learned from the peasants that there were in the vicinity some pits from which they not only quarried excellent marble, but had extracted many statues in the course of years (see Jorio, *Notizia degli scavi d'Ercolano*, Naples, 1827). In 1738, while Colonel D. Rocco de Alcubierre was directing the works for the construction of the "Reali Delizie" at Portici, he received orders from Charles III. to begin excavations on the spot where it had been reported to the king that the Elbeuf statues had been found. At first it was believed that a temple was being explored, but afterwards the inscriptions proved that the building was a theatre. This discovery excited the greatest commotion among the scholars of all nations; and many of them hastened to Naples to see the marvellous statues of the Balbi and the paintings on the walls. But everything was kept private, as the Government wished to reserve to itself the right of illustrating the monuments. First of all Monsignor Bayardi was brought from Rome and commissioned to write about the antiquities which were being collected in the museum at Portici under the care of Camillo Paderni, and when it was recognized that the prelate had not sufficient learning, and by the progress of the excavations other most abundant material was accumulated, about which at once scholars and courtiers were anxious to be informed, Bernardo Tanucci, having become secretary of state in 1755, founded the Accademia Ercolanese, which published the principal works on Herculaneum (*Le Pitture ed i Bronzi d'Ercolano*, 8 vols., 1757, 1792; *Dissertationis Isagogicæ ad Herculanensium voluminum explanationem pars prima*, 1797). The criterion which guided the studies of the academicians was far from being worthy of unqualified praise, and consequently their work did not always meet the approval of the best scholars who had the opportunity of seeing the monuments. Among these was Winckelmann, who in his letters gave ample notices of the excavations and the antiquities which he was able to visit on several occasions. Other notices were furnished by Gori, *Symbolæ litterariæ Florentinæ*, 1748, 1751, by Marcello Venuti, *Descrizione delle prime scoperte d'Ercolano*, Rome, 1748, and Scipione Maffei, *Tre lettere intorno alle scoperte d'Ercolano*, Verona, 1748. The excavations, which continued for more than forty years (1738-1780), were executed at first under the immediate direction of Alcubierre (1738-1741), and then with the assistance of the engineers Rorro and Bardet (1741-1745), Carl Weber (1750-1764), and Francesco La Vega. After the death of Alcubierre (1780), the last-named was appointed director-in-chief of the excavations; but

from that time the investigations at Herculaneum were intermitted, and the researches at Pompeii were vigorously carried on. Resumed in 1827, the excavations at Herculaneum were shortly after suspended, nor were the new attempts made in 1866 with the money bestowed by King Victor Emmanuel attended with success, being impeded by the many dangers arising from the houses built overhead. The meagreness of the results obtained by the occasional works executed in the present century, and the fact that the investigators were unfortunate enough to strike upon places already explored, gave rise to the opinion that the whole area of the city had been crossed by tunnels in the time of Charles III. and in the beginning of the reign of Ferdinand IV. And although it is recognized that the works had not been prosecuted with the caution that they required, yet in view of the serious difficulties that would attend the collection of the little that had been left by the first excavators, every proposal for new investigations has been abandoned. But in a memoir which Professor Barnabei read in the Reale Accademia dei Lincei (*Atti della R. Ac.*, series iii., vol. ii. p. 751), he undertook to prove that the researches made by the Government in the last century did not cover any great area. The antiquities excavated at Herculaneum in the last century form a collection of the highest scientific and artistic value. There are marble statues of astonishing art and perfect preservation, of which it is sufficient to mention the two equestrian statues of the Balbi (*Museo Borbonico*, vol. ii. pl. xxxviii.-ix.) and the so-called statue of Aristocles. With the exception of a few pieces, nearly all the great bronzes of the museum belong to Herculaneum. It is thence that we have obtained the reposing Hermes, the drunken Silenus, the sleeping Faunus, the dancing girls, the bust called Plato's, that believed to be Seneca's, the two quoit-throwers or discoboli, and so many master-pieces more, figured by the academicians in their volume on the bronzes. Mural paintings of extraordinary beauty were also discovered, such as those that represent Theseus after the slaughter of the Minotaur (Helbig, *Wandgemälde*, Leipsic, 1878, No. 1214) and Chiron teaching Achilles the art of playing on the lyre (*ibid.*, No. 1291). Notwithstanding the recent discoveries of the stupendous paintings in the gardens of the Villa Farnesina on the banks of the Tiber, the monochromes of Herculaneum remain among our finest specimens of the exquisite taste and consummate skill displayed by the ancient artists. Among the best preserved is Leto and Niobe, which has been the subject of so many studies and so many publications (*ibid.*, No. 1706). There is also a considerable number of lapidary inscriptions edited in vol. ii. of the epigraphic collection of the *Cal. del Mus. Naz. di Napoli*.

But all these antiquities do not seem to afford adequate support for the opinion of those who, pointing out that those marvels were found for the most part in two or three buildings, conclude that similar riches would be found in other houses if the excavations were resumed. For their contention is that Herculaneum was not only a much greater city than Pompeii, but had attained a more exquisite Greek culture, because a large body of the Greek colonists expelled from the cities of Southern Italy had settled there either through their own numerical strength or through the favour of the Samnite confederation, whose conquests had placed it above all alarm at the advance of an already vanquished race. But in support of these assertions, more proof seems to be required than the fact that only two Samnite inscriptions have been found in Herculaneum (*cf.* Fabretti, *Glossarium Italicum*, No. 2784, 2784 bis), whilst at Pompeii they have been met with in great numbers; since, if it is borne in mind that in a later age Herculaneum was a municipium as well as Pompeii, and had the same political life, we must seek another explanation of the circumstance that in Pompeii there are so many inscriptions relative to municipal affairs, while in Herculaneum there are none. On the other hand, the classical tradition does not force us to believe that the city was so small as the academicians held it to be. The plan published in the *Dissertatio Isagogica* represents nine *insulae* or blocks, each having the proportions of the sides of the Villa Suburbana or Villa Ercolanese discovered in the place called the wood of St. Agostino. It was believed that this place was in the suburb, because it was divided from the rest of the inhabited area by a narrow valley formed by the washing of the rain (*Diss. Isag.*, p. 30). If this was correctly determined, the same cannot be said of the circuit of the city, as the walls have not been discovered. Nor are the investigations sufficient to fix precisely the ancient shore line. The discovery of the Villa Suburbana contributed to magnify the greatness of Herculaneum; within its walls were collected statues of marble and of bronze, and the famous library, of which, counting both entire and fragmentary volumes, 1803 papyri have been preserved. Among the nations which took the greatest interest in the discovery of the Herculaneum library, the most honourable rank belongs to England, which sent Bishop Hayter and other scholars to Naples to solicit the publication of the volumes. Of the 341 papyri which have been unrolled, 195 have been published (*Herculanensium voluminum quæ supersunt*, Naples, 1793-1809; *Collectio altera*, 1862-1876). They contain works by Epicurus, Demetrius, Polistratus, Colotes, Chrysippus, Carniscus, and Philodemus. The names of the authors

Plan of Villa Ercolanese, Herculaneum.

- 2. Marble Pavements.
- 3. Mosaics.
- 4. Marble Belvedere.

are in themselves sufficient to show that the library belonged to a person whose principal study was the Epicurean philosophy. But of the great master of this school only a few works have been found. Of his treatise *Περὶ φύσεως*, divided into 37 books, it is known that there were three copies in the library (*Coll. alt.*, vi.). Quite recently Professor Comparetti, studying the first fasciculus of volume xi. of the same new collection, recognized most important fragments of the *Ethics* of Epicurus, and these he published in 1879 in Nos. ix. and xi. of the *Rivista di Filologia ed Istruzione classica*, Turin. Even the other authors above mentioned are but poorly represented, with the exception of Philodemus, of whom 26 different treatises have been recognized. But all these philosophic discussions, belonging for the most part to an author less than secondary among the Epicureans, fall short of the high expectations excited by the first discovery of the library. Among the many volumes unrolled only a few are of historical importance,—that edited by Bücheler, which treats of the philosophers of the academy (*Acad. phil. index Hercul.*, Greifswald, 1859), and that edited by Comparetti, which deals with the historians (“Papiri ercolanesi inediti,” in *Rivista di Fil. ed Ist. class.* anno iii., fasc. x.-xii.). To appreciate the value of the volumes unrolled but not yet published (for 146 vols. were only copied and not printed), the student must await the appearance of Comparetti’s

paper, “Relazione sui papiri ercolanesi,” read in the Reale Accad. dei Lincei, which will appear in the “Proceedings” of the academy for 1879. Contributions of some value have been made to the study of Herculaneum fragments by Spengel (“Die Hercul. Rollen,” in *Philologus*, 1863, suppl. vol.), and Gompertz (*Hercul. Studien*, Leipsic, 1865-66, cf. *Zeitschr. f. österr. Gymn.*, 1867-1872). There are in the library some volumes written in Latin, which, according to Boot (*Notice sur les manuscrits trouvés à Herculaneum*, Amsterdam, 1845), were found tied up in a bundle apart. Of these we know 18, but they are all so damaged that hardly any of them can be deciphered. One with verses relating to the battle of Actium is believed to belong to a poem of Rabirius. The numerical preponderance of the works of Philodemus led some people to believe that this had been the library of that philosopher. But quite recently Professor Comparetti has come to the conclusion that the library was collected by Lucius Piso Craspinus (see *Pompei e la Regione Sottarrata dal Vesuvio*, Naples, 1879, p. 159 sq.). A new support to the theory of Professor Comparetti is furnished by the epigraphic fragment edited by De Petra (*ib.*, p. 251 sq.); but Dr Mau takes up a counter position,—he is the first to do so,—and shows that the fragment must have another interpretation (*Bull. Inst. di Corr. Arch.*, 1880). Professor De Petra has also published the official notices upon the antiquities unearthed in the sumptuous villa, giving the plan executed by Weber and recovered by chance by the director of excavations, Michele Ruggiero. This plan, which is here reproduced from De Petra’s monograph,¹ is the only satisfactory document for the topography of Herculaneum; for the plan of the theatre published in the *Bullettino archeologico-italiano* (Naples, 1861, i. p. 53, tab. iii.) was executed in 1747, when the excavations were not completed. And even for the history of the “finds” made in the *Villa Suburbana* the necessity for further studies makes itself felt, since there is a lack of agreement between the accounts given by Alcubierre and Weber and those communicated to the *Philosophical Transactions* (London, vol. x.) by Camillo Paderni, conservator of the Portici Museum. It is hoped, therefore, that among the papers recovered by Ruggiero there may be others which will shed light on what remains dark in the topography of the buried city.

Among the older works relating to Herculaneum, in addition to those already quoted, may be mentioned De Brosses, *Lettre sur l’état actuel de la ville souterraine d’Herculée*, Paris, 1750; Seigneur de Corveion, *Lettre sur la découverte de l’ancienne ville d’Herculane*, Yverdon, 1770; David, *Les antiquités d’Herculaneum*, Paris, 1780; D’Ancora Gaetano, *Prospetto storico-fisico degli scavi d’Ercolano e di Pompei*, Naples, 1803; Veunti, *Prime Scoverte di Ercolano*, Rome, 1748; and Romanelli, *Viaggio ad Ercolano*, Naples, 1811. A full list will be found in vol. i. of *Museo Borbonico*, Naples, 1824, pp. 1-11. (F. B.)

HERCULES (Old Latin, *Hercoles*, *Hercles*) is the Latinized form of the mythical Heracles, the chief national hero of Hellas, who has part in all the most important myths of the generation before that which embraces the Homeric warriors at Troy. The name *Ἡρακλῆς* is compounded of *Hera*, the goddess, and the stem of *κλέος*, “glory.” The thoroughly national character of Heracles is shown by his being the mythical ancestor of the Dorian dynastic tribe, while revered by Ionian Athens, Lelegian Opus, and Æolo-Πλατωνίαν Thebes, and closely associated with the Ælæan heroes Peleus and Telamon. The Perseid Alcmena, wife of Amphitryon of Tiryns, was Hercules’s mother, Zeus his father (see *ALCMENE*). After his putative father he is often called Amphitryoniades, and Alcides too, after the Perseid Alcæus, father of Amphitryon. His mother and her husband lived at Thebes in exile as guests of King Creon. By the craft of Hera, his foe through life, his birth was delayed, and that of Eurystheus, son of Sthenelus of Argos, hastened, Zeus having in effect sworn that the elder of the two should rule the realm of Perseus. Hera sent two serpents to destroy the new-born Hercules, but he strangled them. He was trained in all manly accomplishments by heroes of the highest renown in each, until he slew Linus, his instructor in music, with the lyre. Thereupon he was sent to tend Amphitryon’s oxen, and at this period slew the lion of Mount Cithæron. By the subjection of the Minyans of Orchomenus he won Creon’s

¹ The diagram shows the arrangement and proportions of the Villa Ercolanese, *p* indicating pictures, *b* bronzes, *m* marble statues or busts, *pa* papyrus, and *f* fountains. The dotted lines show the course taken by the excavations, which began at the lower part of the plan.

daughter, Megara, to wife. Her children by him he killed in a frenzy induced by Hera. After purification he was sent by the Pythia to serve Eurystheus. The apologue of Prodicus on the *Choice of Hercules* between pleasure and virtue was founded on his obedience to the oracle. Thus began the cycle of the twelve labours:—

1. Wrestling with the Nemean lion.
2. Destruction of the Lernean hydra.
3. Capture of the Arcadian hind (a stag in art).
4. Capture of the boar of Erymanthus, while chasing which he fought the Centaurs and killed his friends Chiron and Pholus, this homicide leading to Demeter's institution of *mysterics*.
5. Cleansing of the stables of Augeas.
6. Shooting the Stymphalian birds.
7. Capture of the Cretan bull subsequently slain by Theseus at Marathon.
8. Capture of the man-eating mares of the Thracian Diomedes.
9. Seizure of the girdle of Hippolyte, queen of the Amazons.
10. Bringing the oxen of Geryones from Erythia in the far west, which errand involved many adventures in the coast lands of the Mediterranean, and the setting up of the "Pillars of Hercules" at the Straits of Gibraltar.
11. Bringing the golden apples from the garden of the Hesperides.
12. Carrying Cerberus from Hades to the upper world.

Most of the labours lead to various adventures called *πάρεργα*. Their common order and selection, due to Apollodorus and Diodorus Siculus, are later than Eripiides, who omits 5, 6, and 7, and seems to count the victory over Cycnus in Phthiotis, the bearing of the heavens for Atlas, and the freeing of the seas from dangerous monsters. In Homer we read of unspecified labours for Eurystheus, of the struggle with the sea monster of the Troad, and of wars. Hesiod mentions labours 1, 2, and 10, and the freeing of Prometheus. It is a mistake to suppose that legends of Hercules's struggles with monstrous embodiments of evil are not of high antiquity, though we cannot say positively which are old and which comparatively late. Some enumerations give only 10 labours. The late lists probably rest partly on astronomical ideas.

On Hercules's return to Thebes he gave his wife Megara to his friend and charioteer Iolaus, son of Iphicles, and by beating Eurytus of Œchalia and his sons in a shooting match won a claim to the hand of his daughter Iole, whose family, however, except her brother Iphitus, withheld their consent to the union. Iphitus persuaded Hercules to search for Eurytus's lost oxen, but was killed by him at Tiryns in a frenzy. He consulted the Pythia about a cure for the consequent madness, but she declined to answer him. Whereupon he seized the oracular tripod, and so entered upon a contest with Apollo, which Zeus stopped by sending a flash of lightning between the combatants. The Pythia then sent him to serve the Lydian queen Omphale. He then with Telamon, Peleus, and Theseus took Troy. He next helped the gods in the great battle against the giants. He took part in the Argonautic voyage and the Calydonian boar hunt, made war against Augeas, and against Nestor and the Pylians, and restored Tyndareus to the sovereignty of Lacedæmon. He sustained many single combats, one very famous struggle being the wrestling with the Libyan Antæus, son of Poseidon and Ge (Earth), who had to be held in the air, as he grew stronger every time he touched his mother, Earth. Hercules withstood Ares, Poseidon, and Hera, as well as Apollo. The close of his career is assigned to Ætolia and Trachis. He wrestles with Achelous for Deianeira ("destructive to husband"), daughter of Æneus, king of Calydon, vanquishes the river god, and breaks off one of his horns, which as a horn of plenty is found as an attribute of Hercules in art. Driven from Calydon for homicide, he goes with Deianeira to Trachis. On the way he slays the centaur Nessus, who persuades Deianeira that his blood is a love-charm. From Trachis

he wages successful war against the Dryopes and Lapithæ as ally of Ægimius king of the Dorians, who promised him a third of his realm, and after his death adopted Hyllus, his son by Deianeira. Finally Hercules attacks Eurytus takes Œchalia, and carries off Iole. Thereupon Deianeira, prompted by love and jealousy, sends him a tunic dipped in the blood of Nessus, and the unsuspecting hero puts it on just before sacrificing at the headland of Cenæum in Enbeæ. Mad with pain, he seizes Lichas, the messenger who had brought the fatal garment, and hurls him on the rocks; and then he wanders in agony to Mount Œta, where he mounts a pyre, which, however, no one will kindle. At last Pæas, father of Philoctetes, takes pity on him, and is rewarded with the gift of his bow and arrows. The immortal part of Hercules passes to Olympus, where he is reconciled to Hera and weds her daughter Hebe.

In one aspect Hercules is clearly a sun-god, being identified, especially in Cyprus and in Thasos (as Makar), with the Tyrian Melkarth. He is again a representative of endurance and effort in the cause of Hellenic civilization and enterprise. Sundry of his exploits may be based on actual achievements of tribes and leaders of men, but it is impossible to unravel satisfactorily the tangled strands which make up this highly elaborate myth, though the separate existence of some is clearly discernible. The close connexion of the hero with both Thebes and Argos suggests actual relations between the two states. The Lydian episode shows traces of Eastern influence. The second, fifth, and sixth labours may be solar, but yet they suggest reclamation of marsh land. The third and twelfth are the most obviously solar, the horned hind representing the moon, and the carrying of Cerberus to the upper world an eclipse. It may be admitted as highly probable that the last episode of the hero's tragedy is a complete solar myth developed at Trachis. The winter sun is seen rising over the Cenæan promontory to toil across to Mount Œta and disappear over it in a bank of fiery cloud. The fatality by which Hercules kills so many friends as well as foes recalls the destroying Apollo; while his career frequently illustrates the Delphic views on blood-guiltiness and expiation. As Apollo's champion Hercules is Daphnephoros, and fights Cycnus and Amyntor to keep open the sacred way from Tempe to Delphi. As the Dorian tutelæ he aids Tyndareus and Ægimius. As patron of maritime adventure (*ἡγεμόνιος*) he struggles with Nerens and Triton, slays Eryx and Busiris, and perhaps captures the wild horses and oxen, which may stand for pirates. As a god of athletes he is often a wrestler (*παλαίμωυ*), and founds the Olympian games. In comedy and occasionally in myths he is depicted as voracious (*βουφάγος*). He is also represented as the companion of Dionysus, especially in Asia Minor. The "Resting" (*ἀναπαυόμενος*) Hercules is, as at Thermopylæ and near Himera, the natural tutelæ of hot springs in conjunction with his protectress Athena, who is usually depicted attending him on ancient vases. The glorified Hercules was worshipped both as a god and a hero. In the Attic deme Melita he was invoked as *ἀλεξίκακος* ("Helper in ills"), at Olympia as *καλλίνικος* ("Nobly-victorious"), in the rustic worship of the Œtæans as *κορνοπίου* (*κόρνοπες*, "locusts"), by the Erythræans of Ionia as *ἰποκτόνος*, ("Canker-worm-slayer"). In Italy he was, like Apollo, Musagetes ("Leader of the Muses"). He was *σωτήρ* ("Saviour"), *i.e.*, a protector of voyagers, at Thasos and Smyrna, and in Italy, where tithes were vowed to him to be spent in entertainment. Games in his honour were held at Thebes and Marathon. In early poetry, as often in art, he is an archer, afterwards a club-wielder and fully-armed warrior. In early art the adult Hercules is bearded, but not long-haired. Later he is sometimes youthful and beardless, always with short curly hair and thick neck, the lower

part of the brow prominent. A lion's skin is generally worn or carried. Lysippus worked out the finest type of sculptured Hercules, of which the Farnese by Glycon is a grand specimen. The infantine struggle with serpents was a favourite subject.

Quite distinct was the Idæan Hercules, a Cretan Dactyl connected with the cult of Rhea or Cybele. The Greeks recognized Hercules in an Egyptian deity *Chom* and an Indian *Dorsanes*, not to mention personages of other mythologies. Hercules is supposed to have visited Italy on his return from Erythia, when he slew Cacus, son of Vulcan, the giant of the Aventine mount in Rome, who had stolen his oxen. To this victory was assigned the founding of the *Ara maxima*. With respect to the Roman relations of the hero, it is manifest that the native myths of Recarnus, or Sancus, or Dius Fidius, were transferred to the Hellenic Hercules.

The best account of the Hercules myths and cults is by L. Preller, *Griechische Mythologie*, 3d ed., Berlin, 1875. See also Hillan, *De Hercules Romani fabula et cultu*, Münster, 1850; and Bréal, *Hercule et Cacus*, Paris, 1863.

HERDER, JOHANN GOTTFRIED VON (1744-1803), one of the most prolific and influential writers that Germany has produced, was born in Mohrungen, a small town near Königsberg, in 1744. Like his contemporary Lessing, with whose literary aims his own had so much in common, Herder had throughout his life to struggle against adverse circumstances. His father was poor, having to put together a subsistence by uniting the humble offices of sexton, choir singer, and petty schoolmaster. Gottfried seems to have got some rudimentary instruction from his father, after which he was sent to the grammar school (gymnasium) of his native town. The mode of discipline practised by the pedantic and irritable old man who stood at the head of this institution was not at all to the young student's liking, and the impression made upon him stimulated him later on to work out his projects of school reform. The hardships of his early years drove him to introspection and to solitary communion with nature, and thus favoured a more than proportionate development of the sentimental and poetic side of his mind. When quite young he expressed a wish to enter the church, but his aspirations were somewhat rudely discouraged by the local clergyman. In 1762, at the age of eighteen, he went up to Königsberg with the intention of studying medicine, but finding himself unequal to the operations of the dissecting-room, he abandoned this object, and by the help of one or two friends and his own self-supporting labours, followed out his earlier idea of the clerical profession by joining the university. There he came under the influence of Kant, who was just then passing from physical to metaphysical problems. Without becoming a disciple of Kant, the young Herder was deeply stimulated to fresh critical inquiry by that thinker's revolutionary ideas in philosophy. To Kant's lectures and conversations he further owed something of his large interest in cosmological and anthropological problems. Among the writers whom he most carefully read were Plato, Hume, Shaftesbury, Leibnitz, Diderot, and Rousseau. Another personal influence under which he fell at Königsberg, and which was destined to be far more permanent, was that of Hamann, "the northern Mage." This writer had already won a name, and in the young Herder he found a mind well fitted to be the receptacle and vehicle of his new ideas on literature. From this vague, incoherent, yet clever writer our author acquired some of his strong feeling for the natural naïf element in poetry, and for the earliest developments of national literature. Even before he went to Königsberg he had begun to compose verses, and at the age of twenty he took up the pen as a chief occupation. His first published writings were occasional poems

and articles contributed to the *Königsberg Journal*. Soon after this he got a double appointment at Riga, as assistant master at the cathedral school, and as curate to the suburban churches. In this busy commercial town, in somewhat improved pecuniary and social circumstances, he developed the main ideas of his writings. In the year 1767 he published his first considerable work *Fragmente über die neuere deutsche Literatur*, which at once made him widely known and secured for him the favourable interest of Lessing. From this time he continued to pour forth a number of critical writings on literature, art, &c. His bold ideas on these subjects, which were a great advance even on Lessing's doctrines, naturally excited hostile criticism, and in consequence of this opposition, which took the form of aspersions on his religious orthodoxy, he resolved to leave Riga. He was much carried away at this time by the idea of a radical reform of social life in Livonia, which (after the example of Rousseau) he thought to effect by means of a better method of school-training. With this plan in view he began (1769) a tour through France, England, Holland, &c., for the purpose of collecting information respecting their systems of education. It was during the solitude of his voyage to France, when on deck at night; that he first shaped his idea of the genesis of primitive poetry, and of the gradual evolution of humanity. Having received an offer of an appointment as travelling tutor and chaplain to the young prince of Eutia-Holstein, he abandoned his somewhat visionary scheme of a social reconstruction of a Russian province. He has, however, left a curious sketch of his projected school reforms. His new duties led him to Strasburg, where he met the young Goethe, on whose poetical development he exercised so potent an influence. At Darmstadt he made the acquaintance of Caroline Flachsland, to whom he soon became betrothed, and who for the rest of his life supplied him with that abundance of consolatory sympathy which his sensitive and rather querulous nature appeared to require. The engagement as tutor did not prove an agreeable one, and he soon threw it up (1771) in favour of an appointment as court preacher and member of the consistory at Bückeburg. Here he had to encounter bitter opposition from the orthodox clergy and their followers, among whom he was received as a free-thinker. His health continued poor, and a fistula in the eye, from which he had suffered from early childhood, and to cure which he had undergone a number of painful operations, continued to trouble him. Further, pecuniary difficulties, from which he never long managed to keep himself free, by delaying his marriage, added to his depression. The correspondence between Herder and Caroline Flachsland indicates a relationship which offers a curious parallel and contrast to that of Lessing and his future wife under very similar circumstances. Notwithstanding these trying circumstances he resumed literary work, which his travels had interrupted. For some time he had been greatly interested by the poetry of the north, more particularly Percy's *Reliques*, the poems of "Ossian" (in the genuineness of which he like many others believed), and the works of Shakespeare. Under the influence of this reading he now finally broke with classicism and became the leader of the new "Sturm und Drang" movement. He co-operated with a band of young writers at Darmstadt and Frankfort, including Goethe, who in a journal of their own sought to diffuse the new ideas of Herder. His marriage took place in 1773. In 1776 he obtained through Goethe's influence the post of upper court preacher and upper member of the consistory at Weimar, where he passed the rest of his life. There he enjoyed the society of Goethe, Wieland, Jean Paul (who came to Weimar in order to be near Herder), and others, the patronage of the court, with whom as a preacher he was very popular, and an opportunity of carrying out some of

his pet ideas of school reform. Yet the social atmosphere of the place did not suit him. His personal relations with Goethe again and again became embittered. He had not the poet-minister's liking for the elegant frivolities of court life, while the efforts of Goethe and Schiller to make Weimar a dramatic centre repelled his austere moral nature. All this, added to ill-health, served to intensify a natural irritability of temperament, and the history of his latter Weimar days is a rather dreary page in the chronicles of literary life. He had valued more than anything else a teacher's influence over other minds, and as he began to feel that he was losing it he grew jealous of the success of those who had outgrown this influence. Yet while presenting these unlovely traits, Herder's character was on the whole a worthy and attractive one. This seems to be sufficiently attested by the fact that he was greatly liked and esteemed, not only in the pulpit but in private intercourse, by cultivated women like the countess of Bückeberg, the duchess of Weimar, and Frau von Stein, and, what perhaps is more, was exceedingly popular among the gymnasium pupils, in whose education he took so lively an interest. While during the last years of his life he produced much that is of little value, he wrote also some of his best works, among others his collection of popular poetry, *Stimmen der Völker*; his most notable original poem, the *Cid*; his celebrated work on Hebrew poetry, *Vom Geist der hebräischen Poesie*; and his *opus magnum*, the *Ideen zur Philosophie der Geschichte*. Towards the close of his life he occupied himself like Lessing with speculative questions in philosophy and theology. The boldness of some of his ideas cost him some valuable friendships, as that of Jacobi, Lavater, and even of his early teacher Hamann. He died in the year 1803, full of new literary plans up to the very last.

Herder's writings were for a long time regarded as of temporary value only, and fell into neglect. Recent criticism, however, has tended very much to raise their value by tracing out their wide and far-reaching influence. The number of publications relating to Herder that have appeared during the last few years shows that there is a revival of interest in this writer. His writings are very voluminous, and to a large extent fragmentary and devoid of artistic finish; nevertheless they are nearly always worth investigating for the brilliant suggestions in which they abound. His place in German literature has already been faintly indicated in tracing his mental development. Like Lessing, whose work he immediately continued, he was a pioneer of the golden age of this literature. Lessing had given the first impetus to the formation of a national literature by exposing the folly of the current imitation of French writers. But in doing this he did not so much call his fellow-countrymen to develop freely their own national sentiments and ideas as send them back to classical example and principle. Herder on the contrary fought against all imitation as such, and bade German writers be true to themselves and their national antecedents. As a sort of theoretic basis for this adhesion to national type in literature, he conceived the idea that literature and art, together with language and national culture as a whole, are evolved by a natural process, and that the intellectual and emotional life of each people is correlated with peculiarities of physical temperament and of material environment. In this way he became the originator of that genetic or historical method which has since been applied to all human ideas and institutions. Herder was thus an evolutionist, but an evolutionist still under the influence of Rousseau. That is to say, in tracing back the later acquisitions of civilization to impulses which are as old as the dawn of primitive culture, he did not, as the modern evolutionist does, lay stress on the superiority of the later to the earlier stages of human development, but rather became enamoured of the simplicity

and spontaneity of those early impulses which, since they are the oldest, easily come to look like the most real and precious. Yet even in this way he helped to found the historical school in literature and science, for it was only after an excessive and sentimental interest in primitive human culture had been awakened that this subject would receive the amount of attention which was requisite for the genetic explanation of the later acquisitions of the species. This historical idea was carried by Herder into the regions of poetry, art, religion, language, and finally into human culture as a whole. It colours all his writings, and is intimately connected with some of the most characteristic attributes of his mind, a quick sympathetic imagination, a fine feeling for local differences, and a scientific instinct for seizing the sequences of cause and effect.

Herder's works easily arrange themselves in an ascending series, corresponding to the way in which the genetic or historical idea was developed and extended. First come the works on poetic literature, art, language, and religion as special regions of development. Secondly, we have in the *Ideen* a general account of the process of human evolution. Thirdly, there are a number of writings which, though inferior in interest to the others, may be said to supply the philosophic basis of his leading ideas. (1) In the region of poetry Herder sought to persuade his countrymen, both by example and precept, to return to a natural and spontaneous form of utterance. His own poetry is voluminous, and as a whole has but little value. Herder was a skillful verse-maker but hardly a creative poet. His best poetry consists of translations of popular song, in which he shows a rare sympathetic insight into the various feelings and ideas of peoples as unlike as Greenlanders and Spaniards, Indians and Scotch. In the *Fragmente* he aims at nationalizing German poetry and freeing it from all extraneous influence. He ridicules the ambition of German writers to be classic, as Lessing had ridiculed their eagerness to be French. "Let us," he says, "be idiotistic writers, adapting ourselves to the peculiarities of our people and our language; whether we are classic posterity may find out." In his sweeping condemnation of contemporary writers, he does not exempt even Klopstock, with whose feeling for nature he has so much sympathy, but whose poems appear to him exotic in sentiment and ideas. He looked at poetry as a kind of "proteus among the people, which changes its form according to language, manners, habits, according to temperament and climate, nay, even according to the accent of different nations." This fact of the idiosyncrasy of national poetry he illustrated with great fulness and richness in the case of Homer, the nature of whose works he was one of the first to elucidate, the Hebrew poets (*Geist der hebräischen Poesie*), and the poetry of the north as typified in "Ossian." This same idea of necessary relation to national character and circumstance is also applied to dramatic poetry, and more especially to Shakespeare. Lessing had done much to make Shakespeare known to Germany, but he had regarded him in contrast to the French dramatists with whom he also contrasted the Greek dramatic poets, and accordingly did not bring out his essentially modern and Teutonic character. Herder does this, and in doing so shows a far deeper understanding of Shakespeare's genius than his predecessor had shown. His appreciative criticisms of *Hamlet*, *Othello*, and other plays are worthy of being read along with those of later German critics. (2) The views on art contained in Herder's *Silva*, *Plastik*, &c., are chiefly valuable as a correction of the excesses into which reverence for Greek art had betrayed Winckelmann and Lessing, by help of his fundamental idea of national idiosyncrasy. He argues against the setting up of classic art as an unchanging type, valid for all peoples and all times. He was one of the first to bring to light the characteristic excellences of Gothic art. Beyond this, he eloquently pleaded the cause of painting as a distinct art, which Lessing in his desire to mark off the formative arts from poetry and music had confounded with sculpture. He regarded this as the art of the eye, while sculpture was rather the art of the organ of touch. Painting being less real than sculpture, because lacking the third dimension of space, and a kind of dream, admitted of much greater freedom of treatment than this last. Herder had a genuine appreciation for early German painters, and helped to awaken the modern interest in Albrecht Dürer. (3) By his work on language *Ueber den Ursprung der Sprache*, Herder may be said to have laid the first rude foundations of the science of comparative philology and that deeper science of the ultimate nature and origin of language. It was specially directed against the supposition of a divine communication of language to man. Its main argument is that speech is a necessary outcome of that special arrangement of mental forces which distinguishes man, and more particularly from his habits of reflexion. "If," Herder says, "it is incomprehensible to others how a human mind could invent language, it is as incomprehensible to me how a human mind could be what it is without discovering language for itself." The writer does not make that

use of the fact of man's superior organic endowments which one might expect from his general conception of the relation of the physical and the mental in human development. (4) Herder's services in laying the foundations of a comparative science of religion and mythology are even of greater value than his somewhat crude philological speculations. In opposition to the general spirit of the 18th century he saw, by means of his historic sense, the naturalness of religion, its relation to man's wants and impulses. Thus with respect to early religious beliefs he rejected Hume's notion that religion sprang out of the fears of primitive men, in favour of the theory that it represents the first attempts of our species to explain phenomena. He thus intimately associated religion with mythology and primitive poetry. As to later forms of religion, he appears to have held that they owe their vitality to their embodiment of the deep seated moral feelings of our common humanity. His high appreciation of Christianity, which contrasts with the contemptuous estimate of the contemporary rationalists, rested on a firm belief in its essential humanity, to which fact, and not to conscious deception, he attributes its success. His exposition of this religion in his sermons and writings was simply an unfolding of its moral side. In his later life, as we shall presently see, he found his way to a speculative basis for his religious beliefs. (5) Herder's masterpiece, the *Ideen*, has the ambitious aim of explaining the whole of human development in close connexion with the nature of man's physical environment. Man is viewed as a part of nature, and all his widely differing forms of development as strictly natural processes. It thus stands in sharp contrast to the anthropology of Kant, which opposes human development conceived as the gradual manifestation of a growing faculty of rational free will to the operations of physical nature. Herder defines human history as "a pure natural history of human powers, actions, and propensities, modified by time and place." The *Ideen* shows us that Herder is an evolutionist after the manner of Leibnitz, and not after that of more modern evolutionists.¹ The lower forms of life prefigure man in unequal degrees of imperfection; they exist for his sake, but they are not regarded as representing necessary antecedent conditions of human existence. The genetic method is applied to varieties of man, not to man as a whole. It is worth noting, however, that Herder in his provokingly tentative way of thinking comes now and again very near ideas made familiar to us by Mr Spencer and Mr Darwin. Thus in a passage in book xv. chap. ii., which unmistakably foreshadows Mr Darwin's idea of a struggle for existence, we read: "Among millions of creatures whatever could preserve itself abides, and still after the lapse of thousands of years remains in the great harmonious order. Wild animals and tame, carnivorous and granivorous, insects, birds, fishes, and man are adapted to each other." With this may be compared a passage in the *Ursprung der Sprache*, where there is a curious adumbration of Mr Spencer's idea that intelligence, as distinguished from instinct, arises from a growing complexity of action, or, to use Herder's words, from the substitution of a more for a less contracted sphere.² Herder is more successful in tracing the early developments of particular peoples than in constructing a scientific theory of evolution. Here he may be said to have laid the foundations of the science of primitive culture as a whole. His account of the first dawns of culture, and of the ruder Oriental civilizations, is marked by genuine insight. On the other hand the development of classic culture is traced with a less skilful hand. Altogether this work is rich in suggestion to the philosophic historian and the anthropologist, though marked by much vagueness of conception and hastiness of generalization. (6) Of Herder's properly metaphysical speculations little needs to be said. He was too much under the sway of feeling and concrete imagination to be capable of great things in abstract thought. It is generally admitted that he had no accurate knowledge either of Spinoza, whose monism he advocated, or of Kant, whose critical philosophy he so fiercely attacked. His sympathy with the one and his antipathy to the other were intimately connected with the essential character of his mind, which was more synthetic than analytic, regarded things in their concrete surroundings rather than in abstract isolation. It was but one step more to the man who had learnt to view poetry, art, language, &c., in their connexion with social and physical surroundings, and to conceive of human history in its relation to physical events, to bring together the great aggregates of material and spiritual phenomena under one total conception of a single substance or God. Herder's Spinozism, which is set forth in his little work, *Vom Erkennen und Entfindung der menschlichen Seele*, is much less logically conceived than Lessing's. It is the religious aspect of it which attracts him, the presentation in God of an object which at once satisfies the feelings and the intellect. With respect to his attacks on the critical philosophy in the *Metakritik*, it is easy to understand how his concrete mind, ever alive to the unity of things, instinctively rebelled against that analytic separation of the mental processes which Kant attempted.

However crude and hasty this critical investigation, it helped to direct philosophic reflexion to the unity of mind, and so to develop the post-Kantian line of speculation. Herder was much attracted by Schelling's writings, but appears to have disliked Hegelianism because of the atheism it seemed to him to involve. In the *Calligone*, a work directed against Kant's *Critic of Judgment*, Herder argues for the close connexion of the beautiful and the good. To his mind the content of art, which he conceived as human feeling and human life in its completeness, was much more valuable than the form, and so he was naturally led to emphasize the moral element in art. Thus his theoretic opposition to the Kantian aesthetics is but the reflexion of his practical opposition to the formalism of the Weimar poets.

The most valuable original sources of information on Herder, next to his own works (of which a new edition, critically revised by E. Suphan, is just appearing), are the *Erinnerungen aus dem Leben J. G. von Herder*, by Herder's wife; *J. G. von Herder's Lebensbild*, by his son Emil; and his letters, edited by Düntzer and Herder's grandson. The general reader will find a sufficient account of Herder in a number of recent biographical works. Among these the fullest are Ch. Joret's *Herder et la Renaissance Littéraire en Allemagne* (which unfortunately does not deal with the latter part of his life), and R. Haym's *Herder nach seinem Leben und seinen Werken*. The account of Herder in Hettner's *Literaturgeschichte* is very full and interesting. (J. S.)

HEREFORD, an inland English county on the south Plate
Welsh border, is bounded on the N. by Salop, S. by Monmouthshire and Gloucestershire, E. by Worcestershire, and W. by Radnorshire and Brecknockshire. Its circular shape is indented by spurs of adjacent counties, and its outlying parts have by an Act of William IV. 7 and 8 been incorporated with the counties in which they are situated. Its greatest length from Ludford by Ludlow to the Doward Hills, near Monmouth, is 38 miles; its greatest breadth from Cradley to Clifford, near Hay, 35. Its area according to the census of 1871 is 532,898 statute acres, or 832 square miles. It is divided into 11 hundreds and 221 parishes, and is a bishop's see, of which the cathedral city is the centre of the county.

Its chief rivers are the Wye and Lug. The former, rising near the source of the Severn on the summit of Plinlimmon, forms the boundary between Brecon and Radnor ere it enters Herefordshire near Clifford, and, flowing past Hereford, Ross, and Monmouth, falls into the Severn near Chepstow. A striking feature of the Wye is its sinuosity, especially between Hereford and Monmouth. Its never very effectual navigation has been put an end to by railway enterprise, and its salmon fisheries are now so protected by legal enactment that there is no longer a danger of Hereford apprentices being fed on salmon "ad nauseam." The Lug, a first-rate trout stream, rising in Radnorshire, enters Herefordshire near Presteign, and, passing by Aymestry, Kingsland, and Leominster, joins the Wye below Mordiford Bridge, south-east of Hereford. The Arrow also rises in Radnorshire, and flowing past Kington and Pembridge joins the Lug near Monkland, and the Frome, having its source near Bromyard, joins the same river near Mordiford, while the Ledden runs past Ledbury to join the Severn near Gloucester. All these, as well as the Teme, a boundary line of the north-east of the county, are more or less famous trout streams.

The soil is generally marl and clay, but in various parts contains calcareous earth in mixed proportions. Westward the soil is tenacious and retentive of water; on the east it is a stiff and often reddish clay. In the south is found a light sandy loam. The subsoil is mostly limestone, in some parts the Old Red Sandstone, and a species of red and white veined marble. Where the soil does not rest on limestone, it is sometimes a silicious gravel, or contains fuller's earth and yellow ochres. Limestone, quarried at Aymestry and Nash to the north-west of the county, and at Ledbury, Woolhope, and elsewhere, is successfully applied as a manure for arable land and pasture. For the physical history of the county reference must be made to Murchison's *Siluria*, or Symonds's *Records of the Rocks*, where the upheaval and denudation in the Woolhope valley and over the central dome of Haughwood and similar questions are discussed.

¹ See article EVOLUTION, vol. viii. pp. 760, 761.

² Herder's relation to modern evolutionists is dealt with in F. von Bäreabach's *Herder als Vorgänger Darwins*.

The climate is variable, owing to the damp and fogs, which moisten the earth and account for its great verdure, as well as to its large proportion of timber, not only in parks and on landed estates, but almost on every hedgerow. In spite, however, of the prevalence of rheumatism, Herefordshire is reckoned healthy, ranks high in the statistics of longevity, and enjoys a comparative immunity from diseases of the respiratory organs.

The surface of the county is undulated in long ridges, as if by subterranean ripples. Ash and oak coppices and larch plantations clothe its hill-sides and crests. Its lowlands are studded with pear and apple orchards, of such productiveness that Herefordshire sometimes, as well as Kent, is called the garden of England. The apple crop, generally large, is enormous one year out of four. Twenty hogsheads of cider, which is the county beverage, have been made from an acre of orchard, twelve being the ordinary yield. Hops are another staple of the county, the vines of which are planted in rows on ploughed land. As early as Camden's day a Herefordshire adage coupled Woobley ale with Leominster bread, indicating the county's capacity to produce fine wheat and barley, as well as hops. On the Worcestershire border above 10,000 acres are taken up in hop-plantations, and about Ledbury the clay lands are noted for wheat and hops.

Herefordshire is also famous as a breeding county for its cattle of bright red hue, with mottled or white faces and sleek silky coats. The Herefords are stalwart and healthy, and, though not good milkers, put on more meat and fat at an early age, in proportion to food consumed, than almost any other variety. They produce the finest beef, and are more cheaply fed than Devons or Durhams, with which they are advantageously crossed. As a dairy county Hereford does not rank high. Its small, white-faced, hornless, symmetrical breed of sheep known as "the Ryelands," from the district near Ross, where it was bred in most perfection, made the county long famous both for the flavour of its meat and the merino-like texture of its wool. Fuller says of this that it was best known as "Lempster ore," and the finest in all England. In its original form the breed is extinct, crossing with the Leicester having improved size and stamina at the cost of the fleece, and the chief breeds of sheep on Herefordshire farms at present are Shropshire Downs, Cotswolds, and Radnors, with their crosses. Agricultural horses of good quality are bred in the north, and saddle and coach horses may be met with at the fairs, especially Orleton, Brampton Bryan, and Ilmington. Herefordshire has progressed greatly in farming within the last half century. Turnip and green-crop husbandry, with improved rotation, is the general rule, and an average yield of wheat is from 28 to 30 bushels an acre, while about Ross and the "Old Red" districts a yield of 40 bushels is obtained. Breeders' names from the county are famous at the national cattle shows, and the number, size, and quality of the stock are seen in their supply of the metropolitan and other markets. Prize Herefords are constantly exported to the colonies.

The county has no manufactures to speak of. Woollen goods have never been a successful staple of trade at Hereford; yarns and coarse woollens are made, however, in small quantities at Leominster and Kington. There are iron foundries for agricultural implements at Kington and Ross.

The agricultural returns of Great Britain for 1879 give the following statistics for Herefordshire:—

Corn crops (two-thirds being wheat and barley).....	103,252 acres.
Green crops (of which two-thirds are turnips and swedes).....	34,671 "
Grasses under rotation.....	40,092 "
Permanent pasture.....	246,533 "
Hops.....	5,947 "
Bare, fallow, and uncropped arable land.....	11,098 "
<i>Live Stock.</i>	
Horses.....	21,206
Cattle.....	77,402
Sheep.....	340,741
Pigs.....	24,169

In all but the last item the live stock presents a marked increase on 1878; in corn crops there is a decreased acreage, in green crops and permanent pasture a considerable increase, and the area in hops is the same as in the previous year.

According to the parliamentary return of 1873 the county was divided among 13,731 proprietors, owning a total area of 506,559 acres, with a rental of £224,640. Of the proprietors, 9085 (66 per cent.) held less than 1 acre, and 2478 (18 per cent.) between 1 and 10 acres. The owners of the largest holdings are—J. H. Arkwright, Hampton Court, Leominster, 10,559 acres; A. R. Boughton Knight, Downton Castle, 10,081; R. D. Harley, Brampton Bryan, 9869; Sir George H. Cornwall, Moccas, 6946; Lord Bateman, Shobdon Court, 6815; Earl Somers, Eastnor Castle, 6668; Lord Ashburton, 6583; Major Meysey Clive, Whitfield, 5799; Lady

Emily Foley, Stoke Edith Park, 5660; Sir Henry Cotterell, Garnons, 5006; Sir Henry E. Scudamore Stanhope, Holm Lacy, 5039; Major Peplow, Garnstone, 4928.

In Herefordshire inland navigation was represented in the early part of the century by the Gloucester and Newent and Ledbury canal; but this has been bought up for railway purposes, and the canal from Leominster to Woolferton, and thence eastward to Tenbury and Stouport, has also ceased to exist. Hereford is an important railway centre: the Hereford, Ross, and Gloucester line is now amalgamated with the Great Western; the Shrewsbury and Hereford railway traverses the county southward from Woolferton, via Leominster, to Hereford. The Worcester line from Hereford, via Malvern, connects the county town with Oxford and London by an alternative route of the Midland and Great Western; and the west of the county is served by the Midland line from Hereford to Brecon, while the Hereford, Abergavenny, and Newport line accommodates the south-west. Branch lines run from Eardisley to Kington and Presteign, from Ross to Monmouth, from Worcester to Bromyard, and from Leominster to Kington.

The latest statistics of public elementary schools show about 135 Church of England national or parochial schools, 6 board schools, 3 British and Foreign and 3 Roman Catholic schools in the county. Its population, which was 115,439 in 1851, had increased in 1871 to 125,370. Herefordshire is represented in parliament by 6 members—3 for the county, 2 for Hereford city, and 1 for the burgh of Leominster. Its towns, besides Hereford, are Ross, Leominster, Ledbury, Kington, and Bromyard; of these, Ross and Leominster are the most considerable, though Kington, from its position on the Welsh border, drives a brisk trade. In Kington, Bromyard, Ledbury, and Ross, and such larger villages as Woobley and Orleton, survive many picturesque timber and plaster houses of the 15th and 16th centuries.

History.—The earliest known inhabitants of the county were the Silures, whose stout resistance to the Romans provoked the emperor Claudius to the war of extermination in which Ostorius Scapula took Caractacus prisoner. Coxwall Knoll, Caer Caradoc, and other heights contest the claim to have been the final standpoint against the Romans. Traces of the Danes are found at Wigmore; and in 912 they sailed up the Wye, and carried off from Archenfield the bishop of St David's, who had to be redeemed with a large ransom. By the Normans the county was held on the tenure of repelling the Welsh, and for centuries the Marches of Wales were a debatable ground for Welsh and English. In the struggle between Maud and Stephen there was fighting in and around Herefordshire. When the barons rose against Henry III. their hostilities affected this county, and it was the success of a plot of the earl of Gloucester, Roger Mortimer, and others to effect Prince Edward's escape out of De Montfort's hands that led to his flight to Wigmore, and the subsequent defeat of the barons at Evesham. In the Wars of the Roses a battle was fought on February 2, 1461, at Mortimer's Cross, near Kingsland, between Edward, earl of March (afterwards Edward IV.), and Jasper Tudor and James Butler, earls of Pembroke and Wiltshire, in behalf of Queen Margaret, which resulted in the victory of the Yorkists. The Marches were incorporated in the reign of Henry VIII. In the war between Charles I. and his parliament Herefordshire suffered severely for its loyalty, and Hereford, Goodrich, and Ledbury endured sieges, all but the last ending in disaster to the king's party.

Antiquities.—The only pre-historic memorial in the county is the cromlech of Arthur's Stone on the hill above Bredwardine. A line of British entrenchments stretches from the Severn and from Malvern, where an earthwork is still known as the "Herefordshire Beacon," to Wapley, Croft Ambrey, and Coxwall Knoll, in the north of the county. A branch of the Watling Street road from Uriconium and South Shropshire crosses Herefordshire from Marlow to Longtown. Another Roman road came direct from Gloucester (Glevum) to Ariconium or Weston-under-Penyard, and thence by a short route under Caplar Hill to Magna or Kenchester, but by a longer route to Monmouth, Usk, Abergavenny, and so through Magna to Shrewsbury. Offa's Dyke, the Saxon ruler's line of defence against the Welsh, is still traceable at Moorhampton, near Lyonshall, and beyond Kington. Offa's traditional palace, the scene of his murder of Ethelbert, was at Sutton Walls, a little north of Hereford. The ruins of several Norman castles still exist at Wigmore, Clifford, Goodrich, and Brampton Bryan. Among the most interesting churches of that period are one or two remarkable structures of rare Irish Norman architecture, viz., Kilpeck, Moccas, and the arches of old Shobdon church; besides the Cistercian church of Abbey Dore, and the fine old churches of Ledbury and Leominster.

HEREFORD, the capital city of the above county, is situated on the left bank of the Wye, which is crossed there by a bridge of six arches. The see of Hereford was detached from Lichfield in 673, Putta being its first bishop. The removal of murdered Ethelbert's body from Marden

to Hereford led to the foundation of a superior church, reconstructed by Bishop Athelstan, and burnt by the Welsh in 1055. Re-commenced in 1079 by the first Norman bishop, Robert of Lorraine, it was carried on by Bishop Reynelm, and completed in 1148 by Bishop R. de Betun. The lady chapel, clerestory of the choir, and north transept date between 1226 and 1269, while successive additions and reconstructions have extended over 450 years. In 1786 the great western tower fell and carried with it the west front and the first bay of the nave, since which date there have been two modern restorations, in 1842 and 1863. The total length of the cathedral outside is 342 feet, inside 327 feet 5 inches, the nave being 158 feet 6 inches, the choir from screen to reposed

or thereabouts by a monk of Lincoln, one of the largest and most curious of all the old maps, is preserved in the south choir aisle. The bishop's palace overlooks the Wye on the south of the cathedral, and to the left of it lies the castle green, the site of the historic castle, which is utterly effaced. One only of the six gates of the old walls is still to be seen, but there are ruins of the Black Friars' Monastery in Widemarsh, and a mile out of Hereford on the Brecon Road, the White Cross, erected in 1347 by Bishop Charlton, and restored by Archdeacon Lord Saye and Sele, commemorates the departure of the Black Plague. For its loyalty and sufferings in the civil war Charles I. gave the city its motto "Invictæ fidelitatis præmium." It was incorporated in 1189 by Richard I., and is governed by a municipal council, consisting of a mayor, 6 aldermen, and 18 councillors. It has no manufactures. Its population at the census of 1871 numbered 18,355, or an increase of more than a third in twenty years; its area was 4969 acres. Its public buildings are the shire hall in St Peter's Street, in the Grecian Doric style, with a statue of Sir George Cornwall Lewis in front of it; the corn-exchange (1858), the Rankin free library and Woolhope Club museum in Broad Street, and the Herefordshire middle-class college. The most noteworthy churches are All Saints and St Peter's.

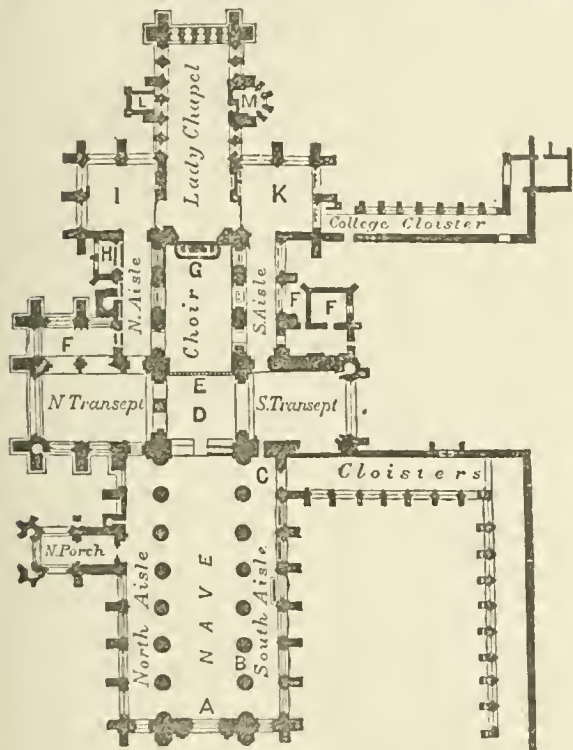

For the bibliography of the city and county of Hereford, see Duncumb's *Collections for a History*; Robinson's *Castles, Manors, and Mansions*, 2 vols., 1869 and 1873; Webb's *History of the Civil War in Herefordshire*, 1879; Havergal's *Fæsti Herefordenses*; Quarterly Review, art. "Herefordshire," July 1879; and the *Woolhope Transactions*. (J. DA.)

HERENCIA, a town of Spain in the province of Ciudad Real, New Castile, is situated in a fertile, hilly region, near the junction of the rivers Giguela and Valdespino, about 80 miles south of Madrid. Soapmaking is the chief industry; coarse cloth, wax, and chocolate are also manufactured. Wheat, barley, vines, and olives are grown in the neighbourhood, where also there is excellent pasturage. Population about 7300.

HEREROLAND, or DAMARALAND, a region of South-Western Africa, stretching north from the Kuisip to the Cunene, so called from the native race known to the Namaqua as Herero and to the Cape colonists as Damara (Damra, or Dama). The north-west portion is also known as Kaokoland.

According to the treaty of Okahandya, by which, in 1876, the country came in some sort under British protection,¹ the boundary line is fixed as coinciding in the south with the line of latitude passing through Rehoboth or Annis (a mission station in 17° 5' E. long. and about 165 miles from the coast), thence in a straight line to Otyimbinde (Tunobis or Riet Fontein), in 20° 53' E. long. and 22° 5' S. lat., thence northwards to Otyiondarmic, and finally from that place westwards along the Omuramba Ovambo to the Cunene. The territory thus defined has an estimated area of 100,000 square miles; and of this about 35,000 square miles were marked out as a British reservation, bounded by a line drawn from Rehoboth to Otyimbinde, thence north-west to Otyituo, about 19° E. long. and 20° S. lat., thence west to Otyahavita, and south to the neighbourhood of Mount Erongo. According to Palgrave the total population of Hereroland is 121,150, of whom 85,000 are Herero proper, 30,000 Hill Damara, 3000 Bushmen, 1500 Namaqua, 1500 Bastards, and 150 Europeans. In a paper in *Petermann's Mittheilungen*, 1878, based on information from the Rhenish missionaries, the total is given as 184,000, of whom 110,000 are Herero (80,000 Ova Herero and 30,000 Ova-mbanderu),

¹ See *Damara and Namaqua Land*: Report of W. Coates Palgrave, Esq., special commissioner to the tribes north of the Orange River, of his mission to Damaraland and Great Namaqualand in 1876. Cape Town, 1877.

Plan of Hereford Cathedral.

- | | | |
|-----------------------|----------------------------|-----------------------|
| A. West Door. | E. Choir Screen. | I. N.E. Transept. |
| B. Font. | F. Vestries. | K. S.E. Transept. |
| C. Door to Cloisters. | G. Altar. | L. Entrance to Crypt. |
| D. Central Tower. | H. Bp. Stanbery's Chantry. | M. Audley Chapel. |

75 feet 6 inches, and the lady chapel 93 feet 5 inches. The breadth of the nave (span of roof) is 31 feet 4 inches, the nave and aisles, internally, 73 feet 4 inches, and the central transept 146 feet 2 inches. The height of choir is 62 feet 6 inches, of nave 64 feet, of lantern 96 feet, of tower to top of the leads 140 feet 6 inches, and to the top of the pinnacles 165 feet. The pillars and arches of the nave, the north and south arches of the choir, and the triforium are Norman in their architecture, as is also the font; the lady chapel, the clerestory, and stone vaulting, Early English. The north transept is of the date of Bishop Aquablanca (1245-68), the south-east transept of Late Decorated. As the late Sir Gilbert Scott pointed out at Hereford to the Archaeological Institute, but for the fall of the western tower, the consequent curtailment of the nave, and other solecisms, few cathedrals could offer so complete a field of progressive architectural study from Early Norman to latest Perpendicular. The cathedral can boast some fine monuments, notably St Thomas of Cantilupe's shrine in the north transept, and Bishop Aquablanca's tomb. The "Mappa Mundi," compiled in 1300

50,000 Hill Damara, 2500 Namaqua, 2000 Bastards, 20,000 Bushmen, and 300 whites.

Hereroland has a coast-line of 460 miles, but the only point where it offers shelter and access to ships is Walfish Bay, a safe but comparatively shallow harbour formed by Pelican Point immediately to the south of the mouth of the Kuisip. The country consists of three distinct physical regions—first, a long and narrow coast district backed by a very regular line of hills, of which the highest point appears to be Mount Messum or Dourissa; secondly, a broad mountainous tract, containing in the south such peaks as Omatako, 8800 feet, Ombotzu (Diambotodzu), 7300, Etyo, 4000, and far in the north Etendeka, 4000; and thirdly, a steppe region which stretches away into the Kalahari desert. The rivers of Hereroland, of which the most important, passing from south to north, are the Tsoachaub, the Eisib or Omaruru, the Ugab, and the Huab, are mere wadies, which only at intervals succeed in bringing water as far as the sea. Except in the half-dry river-beds, the coast district is almost destitute of vegetation, the only edible fruit being the *nara*, which grows on the sand-dunes, and is, according to Anderson, eaten by oxen, mice, men, ostriches, and lions. In the mountainous tract there are places of considerable fertility; large trees, as sycamores, &c., grow along the river-beds, and euphorbias, tamarisks, and a variety of strong-spined bushes prevail. In a few favoured spots wheat can be cultivated, and from a single grain as many as 150 stalks may be produced. The coast range and many of the mountains, such as Okonyonyo and Amatako, are composed of granite and gneiss, broken by intrusive quartz and porphyry; further east limestone formations, both Carboniferous and Oolitic, are predominant; and these again give place to sandstone strata, which are weathered into table-shaped eminences. The granite and gneiss are being disintegrated with great rapidity. Both iron and copper are said to occur in considerable abundance, though the mineral exploitation of the country has had no satisfactory result. About 25 mineral springs, both hot and cold, are known to exist among the mountains.

An interesting sketch of the climate was contributed by Dr A. von Danckelmann to the *Zeitschr. der österr. Gesellsch. für Meteor.*, 1878. Owing, it would appear, to the cold current in the neighbouring sea, the coast region is almost rainless; though occasionally, in the rainy season of the interior, storm-clouds with thunder and lightning come from the east, and from September to March south-west winds laden with heavy mist blow almost without interruption. In the interior the year is divided into a regular dry and wet season, the former lasting from May to November. From September onwards the air is so clear that the planet Venus can be distinguished at midday, and every object looks so distinct that it is almost impossible to calculate distances correctly. Even during the rainy season the nights are usually cloudless. Not unfrequently before the beginning of the rains "sand-spouts," or, as they are called by the natives, *Kumb'abara* or "rain-beggars," drive across the country. No support is afforded by the observations in Hereroland to the theory of the periodicity of African rain in accordance with the changes of the sun spots; but there would seem to be a gradual decrease of atmospheric precipitation. From September to December the east wind usually blows in the morning, but it passes round to the north-west in the forenoon. From December to April the east is decidedly predominant. Snow is extremely rare, but night frosts occur several times a year, and ice has been found inch thick. In the dry season the daily range of the thermometer is from 32° or 36° Fahr. to 75° or 79°; in the rainy season from 86° or 95° to 68° or 82°.

The Herero are the dominant race. They are well-formed, of good stature, and of regular features. Their complexion is usually dark but not black; but there is sufficient variety to lead them to classify themselves into the *Ovathorundu* or "red folks" and the *Ovatherandu* or "dark folks." Their scanty clothing consists mainly of skins and leather thongs, and both their garments and their bodies are thickly smeared with ochre and grease. The women's head-dress is a curious three-eared helmet. *Assegais*, bows and arrows, and knobsticks or *kieries* are the native weapons, but guns and even breechloaders are growing not uncommon. The whole race is in the pastoral stage, and some of the chiefs possess very extensive property in cattle. The various clans or "uandas" have each its own totem;

and thus to one man it is a sin to partake of the flesh of a red cow and to another a one-horned sheep is equally sacred. By their language (*Otyiherero*) the Herero belong to the great Bantu family. For our acquaintance with it we are mainly indebted to the Rhenish missionaries, and more particularly to Dr Hahn, who published *Grundzüge einer Grammatik der Herero*, Berlin, 1857. A spelling book (Cape Town, 1848) appears to be the earliest work printed in the tongue.

The Herero would seem to have come from the north, and they probably first appeared to the south of the Cunene about 150 years ago, to the disnay of the Hill Damara (*Houquoin*, *Ihaukoin*, *Ovazoratu*, or *Ghoudamoup*), a peculiar race who now occupy the fastnesses of the country, and speak the Nama or Hottentot language with a foreign accent, though there is no tradition of their having used any other. The Herero were subjugated by Jonker Afrikaner, and for a time were scattered among the Namaqua tribes, but about 1865 they recovered their independence. They are still unfriendly to the Hill Damara, who steal their cattle, and they are beginning to hunt down the Bushmen. A single tribe of the Namaqua, which sided with them in their war of liberty, is still settled near Mount Erongo.

Besides the works already mentioned, and the travels of Baines, Galton, and Anderson, see Hahn, "Die Ova-Herero," in *Zeitsch. für Erdkunde*, Berlin, 1868 and 1869, and "Reise im Lande der Herero," in *Petermann's Mittheilungen*, 1873.

HERESY is the English equivalent of the Greek word *αἵρεσις*, which has had a somewhat varied ecclesiastical use. The first employment of the word in the New Testament is to denote a sect or school of opinion among the Jews. We read of the heresy of the Sadducees (*αἵρεσις τῶν Σαδδουκαίων*, Acts v. 17), the heresy of the Pharisees (*αἵρεσις τῶν Φαρισαίων*, Acts xv. 5), and St Paul speaking to Agrippa says, "After the straitest heresy of our religion I lived a Pharisee" (*κατὰ τὴν ἀκριβεστάτην αἵρεσιν τῆς ἡμετέρας θρησκείας*, &c., Acts xxvi. 5). Christianity itself was in the beginning looked upon as one of those sects or schools of Jewish opinion, and the "heresy" of the Nazarenes (Acts xxiv. 5) is spoken of as well as the heresy of the Pharisees (*cf.* Acts xxiv. 14, Acts xxviii. 22). This use of the term is plainly borrowed from classical Greek, where *αἵρεσις* frequently means a school of Roman jurists or a school of philosophy (*cf.* Cic., *Epis. ad Fam.* xv. 16; Diog. Laert., *Proem.*, 13). In the New Testament the word is used in another sense which is purely ecclesiastical. Thus in Titus iii. 10 the apostle says: "A man who is an *heretic* after the first and second admonition reject"; in 2 Pet. ii. 1 the church is warned against false teachers, "who privily shall bring in damnable *heresies*, even denying the Lord that bought them," and these heretics and false teachers are evidently the same as those of whom Paul, in the Epistle to the Galatians, says that they are to be anathematized. They are men who in the name of Christ preach such doctrines as tend to frustrate the grace of Christ, who preach "another gospel" (Gal. i. 8, 9); they are compared to the false prophets of the Old Testament Scriptures; they cause divisions and schisms in the church (1 Cor. xi. 18, 19); and the heresies they are guilty of are classed along with grave moral offences (Gal. v. 20). It is this second New Testament use of the word which was taken over into ecclesiastical terminology, and it is in this sense that the early Christian writers speak of heresy and heretics. This early ecclesiastical use has continued down to the present, save that in earlier times schism was generally included under heresy, the names and the things not being separated by definition. It is interesting, however, to notice that the earlier New Testament use of the word seems to have lingered on. Tertullian (*Apolog.*, c. 1) calls the church a *sect*, which is the Latin equivalent for *heresy*, and in the same way Constantine called the church (*Eusebius, H.E.*, x. 5, §§ 21-22) *ἡ αἵρεσις ἡ καθολικὴ ἡ ἀγνωστῆρ αἵρεσις*.

Heresy means a grave error in matters of faith, but it is much more than a theological or ecclesiastical term. From the days of the emperor Theodosius at the latest, the Christian religion has been intimately connected with law, and heresy is a legal term, with a definite meaning attaching

to it; a heresy was a crime with punishment annexed, and therefore was capable of legal definition. It was an offence in canon law, and it was also for long an offence according to civil law. The theological meaning, and the definitions according to canon law and according to civil law respectively, are all different from each other and must be separately explained.

1. *The Theological Sense of the Term.*—The early Christian writers say a great deal about heresy, but commonly refrain from telling what it is. They describe heresies, but they only denounce heresy. It is vain to look for a definition of it in Irenæus's *Against Heresies*, in Hippolytus's *Refutation of all Heresies*, in Tertullian's *Prescription against Heretics*. It is possible, indeed, to collect from these one or two leading tests of heresy, but no definition is to be found. The common features of heresy are too well known to call for specific enumeration. We can gather from Irenæus that heretics are those who reject Scripture, who refuse to accept the "doctrina tradita," who deny the authority of the clergy who have come in regular succession from the apostles, who keep aloof from the Catholic Church, the sole depositary of apostolic doctrine (*Against Heresies*, iii. 2-4). Tertullian, in his usual succinct manner, calls every man a heretic who does not at once accept the "Regula Fidei," and he refuses to argue with such a man even though the heretic proceeds to adduce arguments from Scripture. "A controversy over Scripture with heretics can clearly produce no other effect than to help to upset either the stomach or the brain" (*Præscr. adv. Hær.*, 16). In the Eastern Church, after the period of the œcumenical councils, Tertullian's test was the touchstone of heresy. The church had her rule of faith expanded into the Nicæo-Constantinopolitan creed, with the various explanations added in the symbols of the remaining œcumenical councils, and a heretic was one who denied this creed in whole or in part. In the Western Church, on the other hand, theologians were accustomed to define heresy in a vague way. Thus Jerome calls heresy "perversum dogma"; a heretic, with him, is one who interprets Scripture in other fashion than according to the witness of the Spirit of God; and Augustine summarily defines heresy to be the invention or retention of new and false opinions. But whatever the definition, the rough and ready test was always nonconformity to the "formula fidei præscripta ab ecclesia Romana." Instead of definition the Eastern Church simply points to the creed and the œcumenical councils, the Western Church to the rule of faith enjoined by Rome.

These meagre definitions, extracted from the writings of early theologians, all of them going back in the last resort to the recognized creed of the church for the time being, imply, in spite of their vagueness, that there is a certain essential kernel of doctrine in Christianity, which cannot be denied or challenged without involving the destruction of Christianity itself, and they all point the way to a fuller description of what is meant by heresy in the theological sense of the word. Heresy is a doctrine which, with the appearance of Christian doctrine, is really contradictory to the essential nature of Christianity, and, if persisted in, would in the end make Christianity something very different from what it really is. In order, therefore, to say what heresy is, it is necessary to know what the essential nature of Christianity is, and therefore heresy is generally described by reference to the fundamental nature of Christianity, while the real nature of Christian doctrine is commonly brought out by contrasting it with heresy.

When we look at the matter historically we see that Christianity has always taken the shape of a community thinking and acting for the most part together, and that it has always implied a common life, common work, common

ideas. Christianity appears in history as a community whose common work is to confess and to adore God because of what He has done for His people in salvation. This twofold work of confession and worship has manifested itself in a double organization,—an organization of thought and an organization of work,—doctrine and polity. There may be the church without a creed, and the heart-church without the *congregatio*; but that is not the way in which Christianity has taken actual historical shape. It is possible to conceive the entrance of a heterogeneous element into this organization on either side. A heterogeneous element, something really foreign to it, may become organized with the church's doctrine, or may have become incorporated in the church's polity, and whenever this happens there is a doctrine, apparently Christian, which is really subversive of Christianity, there is a polity which, apparently Christian, is really opposed to the real life of the *congregatio*. This possibility is the historical root of the origin both of heresy and of schism; for heresy is just a heterogeneous element imbedded in the organized dogmatic of the church, and schism is a foreign element which has found its way into church polity. This description, however, is somewhat misleading, because it may happen that an element which seems heterogeneous is not really so, but is on the contrary a true part of the organization. Heresy is not only apparently but really foreign to the system in which it has become incorporated. Its nature is different, and its source is different. Mere apparent incongruity, therefore, does not prove heresy. A doctrine must be seen to be really contradictory to the fundamental facts of Christianity, and to have come from a different source, before it can be called a heresy. It has frequently happened, accordingly, that doctrines have been judged heretical which a better acquaintance with the nature of Christianity would have pronounced orthodox.

Christianity, under the many forms which it assumes, has always implied the reconciliation of God and man through the person and work of Christ. It implies that Jesus Christ the Saviour has so brought it about that He has established a new kingdom of God which will last, in which men have communion with God through His Spirit. Christianity is complete when the kingdom of God is fully established. "Thy kingdom come" is its aspiration. It therefore implies a moral separation between God and man—a separation which is overcome by the work of Christ the Mediator. The idea of reconciliation is the central thing in Christianity, the essential part in its description. God, man unable to approach God until reconciliation has been made, Christ the Mediator who reconciles, and His people brought again into communion with God,—all Christian doctrine rings the changes on these four fundamental ideas. Whatever contradicts or tends to destroy these, or their relations to each other, is incompatible with Christianity. Whenever any of these four ideas—God, man, Christ, and the kingdom of God—are so misread as to introduce notions incompatible with the relations in which they stand to each other in Christianity, then heresy enters. Theology therefore (and Protestant theology only carries the idea somewhat further) has usually recognized four kinds of heresy, corresponding to the four fundamental ideas on which Christian doctrine rests. The nature and character of God and of His relation to the universe and to man may be so misread as to make reconciliation an impossible thing, and so also may the nature of Christ, the nature of man, and the nature of the results of Christ's work among men. Hence arise heresies about God, about the person of Christ, about the nature of man, and about the results of Christ's work—all of them being doctrines which are incompatible with the idea of reconciliation.

I. Reconciliation implies that man has been separated by sin from God, and that God can overcome this separation. All descriptions of God, of His nature, character, and works, which contradict this fact may give rise to heresies. Thus God cannot overcome the separation if it be impossible for Him to project Himself beyond Himself for salvation. The nature of the Godhead may be so described as to contradict the idea of reconciliation, as, *e.g.*, in the Arian heresy. Again, all descriptions of God's relations to the universe which imply that the universe and all things are not absolutely dependent on Him, which imply that His gracious purpose can be thwarted, contradict the idea of reconciliation, and so may give rise to heresies, *e.g.*, the Gnostic doctrine that matter is independent of God. Misstatements about God's relation to Himself and about His relation to the universe give rise to two different kinds of heresy.

II. Reconciliation implies a real mediator who can accomplish the reconciliation on both its sides, and so heresies may arise about the nature of Christ. The Saviour may be so described that there is no real mediation, and no real reconciliation. These errors may arise in two ways, as one or other side of the mediator is described. The Saviour may be represented so that He has no real relation to God on the one hand or to man on the other. He may be described in such a way that there is no solidarity between Him and God, as *e.g.*, in the Ebionite heresy; or He may be described in such a way that there is no solidarity between Him and man, as in the Docetist heresy. Misstatements about the relation of Christ to God and the relation of Christ to man give rise to two different kinds of heresy.

III. Reconciliation implies that man is so separated from God by sin that there is real need for salvation, and yet not so separated that he cannot be brought into communion with God again; and the nature of man, and especially the presence of sin in man, may be so described as to set aside these requirements. The fact of sin and its presence in man may be so explained away as to leave little ground for the necessity of reconciliation, *e.g.*, in the Pelagian heresy. Again, on the other hand, the fact and presence of sin may be so described that there is no capacity in man for salvation; it may be alleged that sin belongs to the essential nature of man and cannot be removed, *e.g.*, in the Manichean heresy. These two misstatements about the connexion between man and sin give rise to two kinds of heresy.

IV. The results of the reconciliation effected by Christ may also be misrepresented in two ways. The separation between man and God, which is the formal occasion of the reconciliation, was caused by sin; and the distance between God and man is a moral one. It is not such a separation as might arise from the difference between the divine and the human nature, or from the inevitable distance between Creator and creature. And so reconciliation has for its effect, not mere absorption into God, but the restoration of moral communion between God and His people. The intercourse was broken by sin, and the result of reconciliation must be moral; it must take effect in a change of will, in the creation of a life of new obedience. False ideas arise when this is misrepresented, and these misrepresentations can arise in two ways:—when it is said that the action of divine grace impregnates the nature in a magical way, instead of taking effect on the will in a moral fashion, *e.g.*, the magical idea of sacramental efficacy; or when it is said that the result of the reconciliation is to raise man above the necessity of living a moral life and of conforming to the laws of morality, *e.g.*, the Antinomian heresy.

Thus theology finds at least eight separate kinds of heresy, arising from the entrance of foreign elements into the four fundamental ideas of Christianity. All heresies may be reduced to one or other of these eight classes. In point of fact, however, most heresies which have actually arisen cannot be said to belong purely to any one of them. The class only denotes the type; for one error is apt to bring others in its train, and so most heresies are mixed, and do not in all respects conform to their type.

Theologians, however, have not rested content with the mere theoretical or genetic description of heresy and heretics, and have commonly borrowed distinctions first laid down by jurists in canon law to distinguish more narrowly the characteristic marks of heresy. Thus a false doctrine to be a heresy must be an *intellectual* error, it must be held *voluntarily*, it must contradict a doctrine *already defined* by the formula of the church, it must be held *pertinaciously*, and the heretic must be professedly *within the church*; but these distinctions belong properly to the legal aspect of heresy, and must be referred to again.

Many theologians, Schleiermacher among others, have

attempted to describe the actual origin of heresies, and a common mode of explanation is as follows. Heresies arise in that province of theology called dogmatic, and commonly appear during the definition of some important part of dogmatic theology. Dogmatic theology is the rationale of the spiritual events and forces which have called Christianity into being. In the attempt made by the church to understand these events and forces which have called it into being, its attention has commonly been confined to the more outstanding portions. The history of dogmatic shows us that from time to time the church has endeavoured to master one doctrine, not the whole round of doctrines; it has endeavoured to make distinct single points, instead of working at the various relations of all the doctrines to each other. This very natural mode of work has the one disadvantage that it concentrates attention on isolated portions of doctrine rather than on the whole mass, and between the consecutive portions there are gaps. The mind of man, however, like nature, abhors a vacuum, and summarily fills these vacua up with material usually drawn from the prevailing philosophical or scientific theories of the day. These summary explanations or theories may or may not be in accordance with the spirit of Christianity, and when they are not they become a fruitful source of heresies. One of the best illustrations of this is the introduction into theology of the Aristotelian doctrine of τὸ ἐκούσιον, which gave the church the Pelagian heresy along with some others.

So much for the general theological conception of heresy, of its nature, divisions, and sources; but before proceeding to describe the use of the term in canon law, it should be observed that the theological does not always correspond with the ecclesiastical meaning of the word. It is generally acknowledged that Holy Scripture is the source of doctrine, and that for the due understanding thereof the enlightening guidance of the Holy Spirit is required; though, of course, the precise meaning of this statement varies in different systems of theology. Holy Scripture and the witness of the Spirit of God are thus the touchstone of heresy. In the Roman Catholic and Greek Churches, however, it is held that the enlightening guidance of the Holy Spirit in this respect is restrained within the limits of certain ecclesiastical machinery (the œcumenical council, the pope *ex cathedra*, &c.), which are the only channels through which the Spirit comes to the church, and hence the creed of the church rather than Scripture is the real touchstone of heresy. Protestant theologians, on the other hand, do not believe either that the guidance of the Spirit is always present within this ecclesiastical machinery or that it is given in this way only, and so they make a distinction between mere ecclesiastical and real theological heresies. Ecclesiastical heresies arise when a fundamental statement made in the creed or confession is contradicted. But it may happen, since creeds and councils may err, that the error is not in the contradiction but in the creed, and therefore there is always an appeal from the creed to the Scripture. The ecclesiastical idea of heresy has always the theological idea behind it, and may at any time be corrected by it. Roman Catholic and Greek theologians, on the other hand, do not admit any going behind the record; they do not allow any appeal from the creed to Scripture. According to their ideas the creed is the infallible digest of Scripture, and therefore heresy is to be tested by the creed and not by Scripture—that is, the ecclesiastical and theological ideas of heresy are exactly the same.

2. *Heresy according to Canon Law.*—Canon law was the ecclesiastical law of mediæval Europe, and is still the law of the Roman Catholic Church, and its description of heresy and of heretics is almost more important than the theological in the investigation of the matter from the historical side. Canon law regards heresy

from the practical side of ecclesiastical procedure and legal enactment. Its view is much narrower than the theological, but much more precise. Orthodoxy is the doctrine maintained by the infallible Roman Church and assented to by all its faithful members; heresy is dissent from the articles of faith established by the Roman pontiffs and by the councils of the Roman Church. Canon law also is mainly concerned with heresy in order to punish it, and therefore is obliged to treat the whole subject with severe legal accuracy of statement. It proceeds from strict definitions. Perhaps the commonest definition is the following:—heresy is “error intellectus voluntarius contra aliquam propositionem catholicam cum pertinacia assertus ab eo qui baptismum accepit.” Jurists are accustomed to expand this general definition in a variety of qualifying statements. (a) All heresy is error, but every error is not a heresy. It is an error according to canon law to take usury; it is heresy to say that to take usury is not a sin, but taking usury is no heresy. Heresy is intellectual error. It is intellectual error believed to be truth, and that in spite of predominant opinion. Canonists distinguish between members of the Roman Church who refuse, e.g., to accept the “filioque” clause in the creed, and members of the Greek Church who make the same refusal. The refusal is in both cases an error, but it is a heresy only in the Roman Church, for there only the predominant opinion is against the error. (b) An error also only becomes heresy when it is held voluntarily. To be a heretic a man must stick to his error, although he knows that it has been condemned by the church. A heretic not only errs, but knows that he errs, and wishes to err. (c) Nor is every voluntary error a heresy; the heretic must contradict a doctrine which has been clearly stated in the creed and has become part of the defined faith of the church. (d) Nor is an erroneous opinion voluntarily professed in opposition to the creed of the church heresy, unless the heretic persists in it. Pertinacity, all canonists insist, is an essential element in heresy, and unless it is present no process for heresy can legally proceed. (e) And lastly, a heretic must be a member of the church. He must have been baptized. Neither a Jew, a Mahometan, nor a heathen can be a heretic. They may be unbelievers, they may hold erroneous opinions, but their opinions are not heresies.

From the first qualification, that heresy is an intellectual error, canonists deduce the ground of their enactments against the suspicion of heresy and against those suspected. Canon law uniformly proceeds on the idea that heresy is not merely an error but a crime. It is a crime, however, which belongs to the invisible part of man, to his intellect. It is not something done with his hands or his feet which witnesses can see, and they argue that direct proof is therefore almost impossible, and that the commission of the crime must almost always be proved from suspicions. This suspicion of heresy occupies a very large space in the dissertations of canonists, and the weakness of their position has made them bring in a very great number of reasons which they seem to think strengthen it (see especially Dandinus, *De suspect. de hæresibus*). They carefully define the degrees of suspicion with the conduct appropriate to each: where the suspicion is only “light,” the suspected are simply to be watched; where it is “vehement,” they are to be denounced; where it is “violent,” they are to be treated as heretics. Canonists have carefully analysed and arranged what are reasonable grounds of suspicion. Pope Innocent III. declared that to lead a solitary life, to refuse to accommodate one's self to the prevailing manners of society, and to frequent unauthorized religious meetings were abundant grounds of suspicion; while later canonists were accustomed to give lists of deeds which made the doors suspect;—a priest who did not celebrate mass, a lay-

man who was seen in clerical robes, those who favoured heretics, received them as guests, gave them safe conduct, tolerated them, trusted them, defended them, fought under them, or read their books, were all to be suspect. The canonist rules for suspicion became a sort of inquisitor's *vade mecum*, and when really practised produced a reign of terror.

Since canon law regarded heresy with such horror and detestation, it is not surprising that it gives many directions, which have the force of legal enactments, whereby men may avoid the dangers of heresy. Pope Alexander IV. prohibited laymen from arguing about matters of faith. The council of Toledo (1129), anxious to put down the Albigenses, ordained that every man above fourteen and every woman above twelve years of age should solemnly swear to abjure every heresy and to maintain in its completeness the Catholic faith. Pope Pius IV. ordered the laity to abstain from reading the Scriptures in the vulgar tongue. The promiscuous reading of books was forbidden, and an index of prohibited books believed to be dangerous to faith or morals was formed.

Canon law regards heresy as a crime, and while it recognizes that the power of the church is spiritual, and that the church visits offences with spiritual punishments such as excommunication, it proceeds on the idea that the state should assist the church in suppressing heresy, and visit heretics with civil pains and penalties, including torture and capital punishment; but this side of the history of heresy belongs as much to civil as to canon law. The church, however, did what it could against heretics. The council of Laodicea (can. 6-9) prohibited them from attending service, though from subsequent acts this could not have been enforced. They were not allowed to give evidence in an ecclesiastical court; a father was prohibited from allowing his son or daughter to marry a heretic; social intercourse with them was prohibited, &c.

3. *Heresy according to Civil Law.*—Civil law treats heresy in a still simpler fashion. The legal idea seems to have been that, since the state approved of one creed and gave it public recognition, to profess any other creed was in some sense civil disaffection or a kind of treason, and manifested lack of loyalty. This notion, however, was supplemented by another and much deeper one in the public law of the mediæval empire. According to the ideas of the earlier mediæval jurists, civil government and ecclesiastical government were equally and in the same sense ordinances of God; and this thought found expression in the twin conceptions of world-king and world-priest, emperor and pope, who were God's vicars, and ruled in His name over church and state. God was the king of the world; the emperor was His vicar, and treason, therefore, included treason against God, or heresy, as well as treason against the emperor. This idea lingered long, and indeed still lingers, and complicates the simpler civil notion of heresy. For all practical purposes, however, the deeper thought may be discarded. In civil law, heresy is pertinacious dissent from the creed approved of for the time being. For example, the Lutheran creed, the *Confessio Augustana*, was heresy in all parts of Germany up to the peace of Augsburg, when it was recognized as a creed which might be professed. It then became orthodox in the civil sense of the term, in the same way that the Roman Catholic creed was orthodox, while the Calvinist creed, still unrecognized, was heresy.

Civil punishment followed religious offences as early as the time of Constantine, who enacted severe penalties against the Donatists, and ordained that all possessing Arian books should burn them on the pain of death. Laws against the reading of heretical books became very frequent during and after the 4th century. *Archiepiscopus* and the

reading of books written by the Eunomians a capital offence. Theodosius and Valentinian proscribed Nestorian books, and Valentinian and Marcian the books of Eutyches and Nestorius. The custom became so common that the condemnation of any heresy by the church was followed by the proscription of the writings of members of the sect. The *Codex Theodosianus*, bk. xvi. tit. 5, "De hæreticis," enumerates a great variety of laws against heresy with penalties more or less severe. They had the practical effect of declaring heretics outlaws, who could not hold offices of dignity or value, receive or bequeath money, enforce contracts, &c. In some cases death was the punishment for heresy. Justinian made it impossible for any heretic to bear witness in the civil courts of the land. This legislation may all be traced back to the action of Theodosius, who imposed the Nicene creed upon all his subjects, and made it a law of the land. It continued in force during the Middle Ages, and in consequence heretics who could not accept the Nicene creed were outlaws also. This perhaps explains the curious fact that almost all the mediæval heretics were also revolutionists. During the Middle Ages, especially from the time of Innocent III. onwards, civil interference in cases of heresy was much increased. In the early church the power of discipline belonged to the presbytery, and was afterwards usurped by the bishops, who continued to exercise it in matters of heresy until Innocent III. appointed the Inquisition to deal with heretics. So long as the empire was not Christian, the civil law had nothing to do with the punishment of erroneous opinions, but as soon as Christianity became the authorized religion of the state, the old pagan idea that the state has power to punish *religiones novas et illicitas* was revived. The state, either instructed by the church or, as in the Theodosian code, without instruction, visited with civil pains and penalties all such opinions. This came to a height when the Inquisition was established; and civil courts and national assemblies one after another decreed that whatever penalties were imposed by the Inquisition should be imposed by the state, or else handed over all cases of heresy to the Inquisition to be dealt with as matters deserving the infliction of civil penalties, fines, imprisonment, torture, and death. There is no sadder page in the history of the church than her alliance with the state for the purpose of torturing men out of opinions different from her own. Since the Reformation the persecuting spirit, although tenacious of life, has been gradually dying out.

Principal Heresies.—Early Christian theologians wrote a great many books against heretics in which they enumerated the various heresies which had sprung up in the church up to their own time. St Augustine tells us (*Ep.* 222) that Philastrius, bishop of Brescia, had discovered 28 heresies among the Jews before the coming of Christ, and 128 in the Christian Church afterwards; and many other orthodox writers have given very long lists of these erroneous opinions. It was natural that the early centuries of the Christian era, especially the first five, should be somewhat prolific in heresies, because that was the very period when the church was occupied in defining the principal doctrines of Christianity. A history of heresies must spend most time upon the early centuries. The first dogmatic work of the church was to define the nature of Christ, who occupied the central place in its thought, and it had to steer its way between two opposite views, both of which interfered with the full dogmatic expression of the nature of the Mediator. On the one hand, many of the Jewish converts never rose to the height of the Christian idea of the person of Christ, and it is evident that these must have been very numerous from the emphasis with which it is insisted that Christians should *θεολογῆν τὸν υἱόν*. These Jewish converts preferred to regard the Saviour as the last

of the prophets, one who bore the same relation to God and to man as the prophets did. They shrank from the idea of the incarnation; they seemed to feel no need for the divine Saviour. This theory was of course accompanied by other views about the nature of Christianity, but the main element was opposition to the Christian doctrine of the real divinity of Christ, God who has become man. This Ebionite heresy has been maintained by men who wish to call themselves Christians since these early days, and has taken a great variety of shapes; but whether it is held by Jew or Unitarian, there is the same outline of opinion and the same steadfast repugnance to the doctrine of the incarnation. On the other hand, the philosophic doctrine of the repugnance between matter and spirit, the idea, which runs through all Greek philosophy, that matter is the source of evil, induced many of the early Gentile converts to Christianity to think of the incarnation as a metaphor rather than as a fact. Christ, they thought, did not take, but only seemed to take, a human body. These Docetists, as they were called, had a whole series of successors in the early church. When Christian theology advanced step by step in the definition of the doctrine of the person of Christ, it was this old idea of the repugnance between the divine spirit and human nature embodied that lay at the root of the Apollinarian, Eutychian, and Monophysite heresies. Apollinarianism denied that the Theanthropos had a "reasonable" soul; he denied the full humanity of the Saviour. Eutyches denied that the Theanthropos had a human nature; and the Monophysites, in their various theories, held strongly by the same idea. All these theories, however different in form and expression, denied the full and true humanity of Christ, and so contradicted the church's yearning for a Saviour truly man as well as truly God. These heresies, along with the Nestorian, were all finally condemned at the council of Chalcedon (the fourth œcumenical).

But long before the church had definitely set forth the doctrine of the person of Christ, its attention was turned to the doctrine of the essential nature of the Godhead. At first this doctrine was scarcely considered apart from Christology. It is impossible to separate the history of the doctrine of the Trinity from the doctrine of the person of Christ; for long the two separate problems were inextricably mixed. At length it became evident to the mind of the church that there were two doctrines, and Christian theology turned aside to discuss, and if possible settle, the doctrine of the essential nature of the Godhead before it proceeded to exhaust the doctrine of the person of Christ. For the real problem in the Arian controversy was not the divinity of the Mediator but the nature of God. Is God to be thought of as a Trinity or as a Unity? what is the relation of the Second Person in the Trinity to the First Person? The real gain to Christian theology which came from the discussions in the Arian controversy was to thrust out the Greek conception of Deity as the Absolute who cannot be described save by negations, and to put in its stead a Christian conception which shows that there are motions within the Deity which, however incomprehensible, enable us to know that God may be in sympathy with men, and that all things may live, move, and have their being in Him.

The philosophical idea that matter is the source of evil, that matter has always some stubborn element in it by which it can defy the ideal, gave rise to a whole series of ancient and mediæval heresies. The Gnostics in all their various sects distinguished between God and the Creator. The good God, they held, could not defile Himself by contact with matter, and therefore could not be the God of creation and providence. Christian theology, on the other hand, has always confessed God to be the Almighty Maker

of heaven and earth, and all things seen and unseen, and the necessity for such a doctrine of creation consists in the fact that the Christian consciousness demands the absence of any thing that might come in between God and the furtherance of His plan of salvation. It demands that all things be thought of as dependent on God, in order that He may be able to make all things work together for the good of His people; and so it has strenuously asserted the doctrines of creation and providence in opposition to an independent matter and the reign of fate. The Gnostic ideas were repeated by the Manichæans and by several mediæval sects, such as the Paulicians and Messalians, and, in the Eastern Church, by the Bogomili.

The Pelagian and Manichæan heresies principally concern the Christian doctrine of man and of the presence of sin in man, and contradict the church's creed, because they do away with the Christian doctrine of reconciliation. Pelagianism, it was held, denied the need of God's grace by insisting that man was free from indwelling sin at the beginning of his career, and followed good, when he did follow it, by the power of his own will; while Manichæism, by asserting that sin belonged to the essential nature of man, seemed to paralyse the whole divine action in reconciliation. It was held by the orthodox opponents of Pelagius that his opinions really implied that there was no real need for the Saviour and the salvation which Christianity describes, and that semi-Pelagianism, although much nearer orthodox doctrine, very inadequately comprehended that sinfulness in man which rendered reconciliation indispensable ere there could be a restoration of communion with God.

The Antinomian and various kinds of mystical theories about the Christian life all proceed upon a view of the effects of Christ's work which is at variance with fundamental Christian ideas. Christian doctrine teaches that men reconciled to God will strive to live a life of new obedience to Him, and it holds that this life of new obedience comes under the same moral laws as the ordinary life of man. But many Christian sects have professed theories about this life of new obedience which seem to imply that it is not under the laws of ordinary morality, that Christian freedom means licence to do what ordinary morals forbid. The Epistles to the Corinthians seem to say that such theories were held in the apostolic church, and were denounced by the apostles; many of the Gnostic and Manichæan sects undoubtedly professed them. The same views occur again and again in mediæval heresy, and were held by many of the enthusiastic sectaries in Reformation times and later. The Brethren of the Free Spirit in the 13th and 14th century, the Anabaptists during the Reformation period, and some of the followers of Molinos are examples. The mystical theories which so largely entered into the mediæval church, and which have continually clung to the skirts of Christianity, have in many instances proceeded on the principle that the new life is implanted in man in a physical way, and magical ideas of the means of grace have been very destructive to the moral theory of the Christian life.

The history of the mediæval heretical sects is by far too complicated to be entered on here. Many of them did no more than protest against the hierarchical constitution of the church of the Middle Ages. Most of them only sought room to carry out to the full their ideas of a true "Imitatio Christi," but it is also certain that a good many Gnostic and Antinomian tenets were held. The Friends of God, the Fratricelli, the Beghards, were all mystics, but their mysticism was of a very harmless description; while the Brethren of the Common Life were worthy forerunners of the pietists of the 18th century (see MYSTICS).

The heretics of the Reformation Church scarcely call for separate remark. The Zwickau prophets and the Ana-

baptists held opinions at variance with the ordinary notions of what is meant by the Christian life. Schwenkfeld, the Quietists, the followers of Madamo Bourignon, all revived types of mysticism which had appeared long before; and the Quakers had their forerunners in mediæval times. Many of these sects, though called heretical, seem to have arisen simply from the desire to live purer and more spiritual lives than the church organization of their times permitted, and in order to do so were led to lay stress upon the idea of personal guidance by the Spirit of God, and on the necessity of the "house and heart church" in opposition to the external church life of their time, on the need of personal as opposed to official religion.

In this article Christian heresy alone has been described. Heresy, however, arises wherever there is doctrine, and there are Mahometan and Buddhist heresies and sects as well as Christian.

The best history of sects and heresies from the sympathetic side is Gottfried Arnold's *Unparteiische Kirchen- und Ketzer-Historie*, 1699-1700 (best ed. that of Schaffhausen, 1740). A very good list of writers on heresy, ancient and mediæval, is given in Burton's *Bampton Lectures on Heresies of the Apostolic Age*, 1829. The various Trinitarian and Christological heresies may be studied in Dörner's *History of the Doctrine of the Person of Christ*, 1845-56, Eng. tr., 1861-62; the Gnostic and Manichæan heresies in the works of Mansel, Matter, and Beausobre; the mediæval heresies in Hahn's *Geschichte der Ketzer im Mittelalter*, 1846-50, and Preger's *Geschichte der deutschen Mystik*, 1875; Quietism in Heppes's *Geschichte der quietistischen Mystik*, 1875; the Pietist sects in Palmer's *Gemeinschaften und Secten Württembergs*, 1875; the Reformation and 17th century heresies and sects in the *Anabaptistum et enthusiasticum Pantheon und Geistliches Rüst-Haus*, 1702. Böhmers *Jus Ecclesiasticum Protestantium*, 1714-23, and Van Espen's *Jus Ecclesiasticum*, 1702, detail at great length the relations of heresy to canon and civil law. On the question of the baptism of heretics see Smith and Cheetham's *Dict. of Eccl. Antiquities*, "Baptism of Iteration;" and on that of the readmission of heretics into the church, compare Martene, *De Ritibus*, and Morinus, *De Penitentia*. (T. M. L.)

Heresy according to the Law of England.—The highest point reached by the ecclesiastical power in England was in the Act *De heretico comburendo* (2 Henry IV. c. 15). Some have supposed that a writ of that name is as old as the common law, but its execution might be arrested by a pardon from the crown. The Act of Henry IV. enabled the diocesan alone, without the cooperation of a synod, to pronounce sentence of heresy, and required the sheriff to execute it by burning the offender, without waiting for the consent of the crown.¹ A large number of penal statutes were enacted in the following reigns, and the statute 1 Eliz. c. 1 is regarded by lawyers as limiting for the first time the description of heresy to tenets declared heretical either by the canonical Scripture or by the first four general councils, or such as should thereafter be so declared by parliament with the assent of convocation. The writ was abolished by 29 Car. II. c. 9, which reserved to the ecclesiastical courts their jurisdiction over heresy and similar offences, and their power of awarding punishments not extending to death. Heresy became henceforward a purely ecclesiastical offence, although disabling laws of various kinds continued to be enforced against Jews, Catholics, and other dissenters. The temporal courts have no knowledge of any offence known as heresy, although incidentally (*e.g.*, in questions of copyright) they have refused protection to persons promulgating irreligious or blasphemous opinions. As an ecclesiastical offence it would at this moment be almost impossible to say what opinion, in the case of a layman at least, would be deemed heretical. Apparently, if a proper case could be made out, an ecclesiastical court might still sentence a layman to excommunication for heresy, but by no other means could his opinions be brought under censure. The last case on the subject (*Jenkins v. Cook*, *Law Reports*, 1 Probate Division 80) leaves the matter in the same uncertainty. In that case a clergyman refused the communion to a parishioner who denied the personality of the devil. The judicial committee held that the rights of the parishioners are expressly defined in the statute of 1 Edw. VI. c. 1, and, without admitting that the canons of the church, which are not binding on the laity, could specify a lawful cause for rejection, held that no lawful cause within the meaning of either the canons or the rubric had been shown. It was maintained at the bar that the denial of the most fundamental doctrines of Christianity would not be a lawful cause for such rejection, but the judgment only queries whether a denial of the personality of

¹ Stephen's *Commentaries*, bk. iv. c. 7.

the devil or eternal punishment is consistent with membership of the church. The right of every layman to the offices of the church is established by statute without reference to opinions, and it is not possible to say what opinions, if any, would operate to disqualify him.

The case of clergymen is entirely different. The statute 13 Eliz. c. 12, § 2, enacts that "if any person ecclesiastical, or which shall have an ecclesiastical living, shall advisedly maintain or affirm any doctrine directly contrary or repugnant to any of the said articles, and by convocation before the bishop of the diocese, or the ordinary, or before the queen's highness's commissioners in matters ecclesiastical, shall persist therein or not revoke his error, or after such revocation afterwards affirm such untrue doctrine," he shall be deprived of his ecclesiastical promotions. The Act it will be observed applies only to clergymen, and the punishment is strictly limited to deprivation of benefice. The judicial committee of the privy council, as the last court of appeal, has on several occasions pronounced judgments by which the scope of the Act has been confined to its narrowest legal effect. The court will construe the Articles of Religion and formularies according to the legal rules for the interpretation of statutes and written instruments. No rule of doctrine is to be ascribed to the church which is not distinctly and expressly stated or plainly involved in the *written law of the Church*, and where there is no rule, a clergyman may express his opinion without fear of penal consequences. In the *Essays and Reviews* cases (*Williams v. the Bishop of Salisbury*, and *Wilson v. Fendall*) it was held to be not penal for a clergyman to speak of merit by transfer as a "fiction," or to express a hope of the ultimate pardon of the wicked, or to affirm that any part of the Old or New Testament, however unconnected with religious faith or moral duty, was not written under the inspiration of the Holy Spirit. In the case of *Noble v. Voysey* in 1871, the committee held that it was not bound to affix a meaning to articles of really dubious import, as it would have been in cases affecting property. At the same time any manifest contradiction of the Articles, or any obvious evasion of them, would subject the offender to the penalties of deprivation. In some of the cases the question has been raised how far the doctrine of the church could be ascertained by reference to the opinions generally expressed by divines belonging to its communion. Such opinions, it would seem, might be taken into account as showing the extent of liberty which had been in practice, claimed and exercised on the interpretation of the articles, but would certainly not be allowed to increase their stringency. It is not the business of the court to pronounce upon the absolute truth or falsehood of any given opinion, but simply to say whether it is formally consistent with the legal doctrines of the Church of England. Whether convocation has any jurisdiction in cases of heresy is a question which has occasioned some difference of opinion among lawyers. Hale, as quoted by Phillimore, says that before the time of Richard II., that is, before any Acts of Parliament were made about heretics, it is without question that in a convocation of the clergy or provincial synod "they might and frequently did here in England proceed to the sentencing of heretics." But later writers, while adhering to the statement that convocation might declare opinions to be heretical, doubted whether it could proceed to punish the offender, even when he was a clerk in orders. Phillimore states that there is no longer any doubt, even apart from the effect of the Clergy Discipline Act, 3 and 4 Vict. c. 86, that convocation has no power to condemn clergymen for heresy. The supposed right of convocation to stamp heretical opinions with its disapproval was recently exercised on a somewhat memorable occasion. In 1864 the convocation of the province of Canterbury, having taken the opinion of two of the most eminent lawyers of the day (Sir Hugh Cairns and Mr Rolt), passed judgment upon the volume entitled *Essays and Reviews*. The judgment purported to "synodically condemn the said volume as containing teaching contrary to the doctrine received by the United Church of England and Ireland, in common with the whole Catholic Church of Christ." These proceedings were challenged in the House of Lords by Lord Houghton, and the lord chancellor (Westbury), speaking on behalf of the Government, stated that if there was any "synodical judgment" it would be a violation of the law, subjecting those concerned in it to the penalties of a *præmunire*, but that the sentence in question was "simply nothing, literally no sentence at all." It is thus at least doubtful whether convocation has a right even to express an opinion unless specially authorized to do so by the crown, and it is certain that it cannot do anything more. Heresy or no heresy, in the last resort, like all other ecclesiastical questions, is decided by the judicial committee of the council.

The English lawyers, following the Roman law, distinguish between heresy and apostasy. The latter offence is dealt with by an Act which still stands on the statute book, although it has long been virtually obsolete—the 9 and 10 Will. III. c. 35. If any person who has been educated in or has professed the Christian religion shall, by writing, printing, teaching, or advised speaking, assert or maintain that there are more Gods than one, or shall deny

any of the persons of the Holy Trinity to be God, or shall deny the Christian religion to be true or the Holy Scriptures of the Old and New Testament to be of divine authority, he shall for the first offence be declared incapable of holding any ecclesiastical, civil, or military office or employment, and for the second incapable of bringing any action, or of being guardian, executor, legatee, or grantee, and shall suffer three years' imprisonment without bail. Unitarians were saved from these atrocious penalties by a later Act (53 Geo. III. c. 160), which permits Christians to deny any of the persons in the Trinity without penal consequences. (E. R.)

HERFORD, a town of Prussia, capital of a circle in the government district of Minden, province of Westphalia, is situated in a beautiful and fruitful district at the confluence of the Werra and Aa, and on the Minden and Cologne railway, 19 miles south-west of Minden. It possesses five evangelical churches, among which may be mentioned the Münsterkirche, a Romanesque building with a Gothic apse of the 15th century; the Marienkirche, in the Gothic style; and the Jehanniskirche, with a tower 280 feet high. The other principal buildings are the Catholic church, the synagogue, the gymnasium founded in 1540, the agricultural school, and the theatre. The industries include cotton and flax spinning, and the manufacture of linen cloth, furniture, sugar, tobacco, and leather. The population of the town in 1875 was 11,967.

Herford owes its origin to a nunnery which is said to have been founded in 832, and was confirmed by Louis the Pious in 839. From the emperor Frederick I. the abbess obtained princely rank and a seat in the imperial diet. The foundation was secularized in 1803. Herford was a member of the Hansa League. In 1631 it became a free imperial town, but in 1647 it was subjugated by the elector of Brandenburg. It came into the possession of Westphalia in 1807, and in 1813 into that of Prussia.

HERIOT. See COPYHOLD.

HERIOT, GEORGE (1563–1623), the founder of Heriot's Hospital, Edinburgh, was descended from an old family of some consideration in the county of Haddington; and his father, a goldsmith in Edinburgh, for some time represented the city in the Scottish parliament. George was born in 1563, and after receiving a good education was apprenticed to his father's trade. In 1586 he married the daughter of a deceased Edinburgh merchant, and with the assistance of her patrimony set up in business on his own account. At first he occupied a small "buih" at the north-east corner of St Giles's Church, and afterwards a more pretentious shop at the west end of the building. To the business of a goldsmith he joined that of a money-lender, and in 1597 he had acquired such a reputation that he was appointed goldsmith to Queen Anne, consort of James VI. In 1601 he became jeweller to the king, and on the removal of the court to London, he followed his royal master thither, and occupied a shop opposite the Exchange. Heriot was largely indebted for his fortune to the extravagance of the queen, and to the imitation of this extravagance by the nobility. Latterly he had such an extensive business as a jeweller that on one occasion a Government proclamation was issued calling upon all the magistrates of the kingdom to aid him in securing the workmen he required. He died in London, 10th February 1623. In 1608, having some time previously lost his first wife, he married Alison Primrose, daughter of James Primrose, grandfather of the first earl of Rosebery, but she died in 1612; by neither marriage had he any issue. The surplus of his estate, after deducting legacies to his nearest relations and some of his more intimate friends, was bequeathed to found a hospital for the education of freemen's sons of the town of Edinburgh, and its value afterwards increased so greatly as to supply funds for the erection of several Heriot foundation schools in different parts of the city. For a notice of Heriot's Hospital, see EDINBURGH, vol. vii. p. 666.

Heriot takes a leading part in Scott's novel, *The Fortunes of Nigel* (see also the Introduction). *A History of Heriot's Hospital, with a Memoir of the Founder*, by William Steven, D.D., appeared in 1827, 2d ed. 1859.

HERISAU, the largest town in the Swiss half-canton of Appenzell-ausser-Rhoden, is situated at the confluence of the Glatt and Brühlbach, 7 miles north-west of Appenzell, and about 2550 feet above sea-level. The town is irregularly built, and extends over a large area. The church-tower, in which the archives are kept, is referred to the 7th century. Herisau has a public library, an arsenal, a new town-house, and a hospital, and is the seat of the cantonal council and of a district court of justice. The manufactures comprise muslin, cotton, and silk. Christianity was introduced at Herisau (a name during the Middle Ages Latinized as *Augia Domini*) about the beginning of the 7th century. The nobles of Herisau were its first superiors, but their power passed in 1390 into the hands of the abbots of St Gall, from whose somewhat oppressive rule the people bought themselves free in 1463. The population in 1870 was 9736. In the neighbourhood beautiful walks lead to the interesting ruins of the castles of Rosenberg and Rosenberg. The baths and goat's-whey cure of Heinrichsbad are about a mile to the north-east.

HERISTAL. See HERSTAL.

HERITABLE JURISDICTIONS, in the law of Scotland, were grants of jurisdiction made to a man and his heirs. They were a usual accompaniment to feudal tenures, and the power which they conferred on great families, being recognized as a source of danger to the state, led to frequent attempts being made by statute to restrict them, both before and after the Union. They were all abolished by the Act 20 Geo. II. c. 43, which enacts (§ 1) that all heritable jurisdictions of justiciary, and all regalities and heritable baileries, and all heritable constabularies, other than the office of high constable of Scotland, and all stewardries, being parts only of shires and counties, and all sheriffships and deputy-sheriffships of districts, being parts only of shires and counties, belonging to or possessed by any subject or subjects, shall be taken away and totally dissolved and extinguished. At the same time, constabularies and other jurisdictions having been recognized as rights of property by the Treaty of Union, the Act provides that compensation shall be awarded to all persons lawfully possessed of such jurisdictions, and the sum of £150,000 was afterwards voted by parliament to pay the claims for compensation for loss of jurisdiction, as settled by a report of the Court of Session (see *Erskine's Institutes*, by Nicholson, p. 92).

HERLEN, FRITZ, of Nördlingen, was an artist of the early Swabian school, who tempered the rudeness of his native art with some of the delicacy of the masters of Bruges. The date and place of his birth are unknown, but his name is on the roll of the tax-gatherers of Ulm in 1449; and in 1467 he was made citizen and town painter at Nördlingen, "because of his acquaintance with Flemish methods of painting." One of the first of his acknowledged productions is a shrine on one of the altars of the church of Rothenburg on the Tauber, the wings of which were finished in 1466, with seven scenes from the lives of Christ and the Virgin Mary. In the town-hall of Rothenburg is a Madonna and St Catherine of 1467; and in the choir of Nördlingen cathedral a triptych of 1488, representing the Nativity and Christ amidst the Doctors, at the side of a votive Madonna attended by St Joseph and St Margaret as patrons of a family. In each of these works the painter's name certifies the picture, and the manner is truly that of an artist "acquainted with Flemish methods." We are not told under whom Herlen laboured in the Netherlands, but he probably took the same course as Schongauer and Hans Holbein the elder, who studied in the school of Van der Weyden. His altarpiece at Rothenburg contains groups and figures, as well as forms of action and drapery, which seem copied from those of Van der

Weyden's or Memling's disciples, and the votive Madonna of 1488, whilst characterized by similar features, only displays such further changes as may be accounted for by the master's constant later contact with contemporaries in Swabia. Herlen had none of the genius of Schongauer. He failed to acquire the delicacy even of the second-rate men who handed down to Matsys the traditions of the 15th century; but his example was certainly favourable to the development of art in Swabia. By general consent critics have assigned to him a large altarpiece, with scenes from the gospels and figures of St Florian and St Floriania, and a Crucifixion, the principal figure of which is carved in high relief on the surface of a large panel in the church of Dinkelsbühl. A Crucifixion, with eight scenes from the New Testament, is shown as his in the cathedral, a Christ in Judgment, with Mary and John, and the Resurrection of Souls in the town-hall of Nördlingen. A small Epiphany, once in the convent of the Minorites of Ulm, is in the Holzschuher collection at Augsburg, a Madonna and Circumcision in the National Museum at Munich. Herlen's epitaph, preserved by Rathgeber, states that he died on the 12th of October 1491, and was buried at Nördlingen.

HERMANN, the popular modern name in Germany for the ancient German hero Arminius. See GERMANY, vol. x. p. 475.

HERMANN, commonly distinguished as Hermannus Contractus, *i.e.*, Hermann or Heriman the Lame, an old German chronicler and scholar, was born in 1013, a son of the Swabian Count Wolverad (Wolfrat) of Velheningen (Veringen or Voringen), and died in 1054, at the family residence of Aleshusen near Biberach. Educated at the monastery of Reichenau, and afterwards admitted a member of the fraternity, he added greatly to that reputation for learning which the establishment had maintained from the time of Abbot Berno. Besides the ordinary studies of the monastic scholar, he devoted himself to mathematics, astronomy, and music, and constructed watches and instruments of various kinds.

His chief work is a *Chronicon ab urbe condita ad annum 1054*, which in its earlier portion consists of a compilation from previous chronicles, but between 1044 and 1054 furnishes important and original material for the history of Henry III. The first edition, from a MS. no longer extant, was printed by Richard at Basel in 1529, and reissued in 1530; another edition appeared at St Elaise in 1590 under the supervision of Ussemaun; and a third, from a Reichenau MS., forms part of vol. v. of Pertz's *Monumenta Germanie historica*. A German translation of the last is contributed by Robbe to *Die Geschichtsschreiber der deutschen Vorzeit*. The separate lives of Conrad II. and Henry III., often ascribed to Hermann, appear to have perished. His treatises *De mensura astrolabii* and *De utilitatibus astrolabii* (to be found, on the authority of Salzburg MSS., in Pez, *Thesaurus anecdotorum novissimus*, iii.) being the first contributions of moment furnished by a European to this subject, Hermann was for a time considered the inventor of the astrolabe. A didactic poem from his pen, *De octo vitis principalibus*, is printed in Haupt's *Zeitschrift für deutsches Alterthum* (vol. xiii.); and he is sometimes credited with the composition of the Latin hymns *Veni Sancte Spiritus*, *Salve Regina*, and *Alma Redemptoris*.

HERMANN, FRIEDRICH BENEDICT WILHELM VON (1795-1868), one of the most distinguished of modern writers on political economy, was born on 5th December 1795, at Dinkelsbühl in Bavaria. After finishing his primary education he was for some time employed in a draughtsman's office. He then resumed his studies, partly at the gymnasium in his native town, partly at the universities of Erlangen and Würzburg. His attention seems principally to have been given to mathematics and political economy. In 1817 he took up a private school at Nuremberg, where he remained for four years. After filling an appointment as teacher of mathematics at the gymnasium of Erlangen, he became in 1823 privat-docent at the university in that town. His inaugural dissertation was on the notions of political economy among the Romans (*Disserta-*

to exhibens sententias Romanorum ad economiam politicam pertinentes, Erlangen, 1823). He probably did not remain long at Erlangen, for a year or two after this date we find him acting as professor of mathematics at the gymnasium and polytechnic school in Nuremberg, where he continued till 1827. During his stay there he published an elementary treatise on arithmetic and algebra (*Lehrbuch der Arith. u. Algeb.*, 1826), and made a journey to France to inspect the organization and conduct of technical schools in that country. The results of his investigation were published in 1826 and 1828 (*Ueber technische Unterrichts-Anstalten*). Soon after his return from France he was made professor extraordinarius of political science at the university of Munich, and in 1833 he was advanced to the rank of ordinary professor in the same subject. In 1832 appeared the first edition of his great work on political economy, *Staatswirthschaftliche Untersuchungen* (Economic Researches). In 1835 he was made member of the Royal Bavarian Academy of Sciences.

From this time onwards Hermann's life was one of great and varied practical activity. From the year 1836 he acted as inspector of technical instruction in Bavaria, and made frequent journeys to Berlin and Paris in order to study the methods there pursued. In the state service of Bavaria, to which he devoted himself, he rose gradually but rapidly. In 1837 he was placed on the council for superintendence of church and school work; in 1839 he was entrusted with the direction of the bureau of statistics; in 1845 he was one of the councillors for the interior; in 1848 he sat as member for Munich in the national assembly at Frankfurt. In this assembly Hermann, with Heckscher and Sommaruga, was mainly instrumental in organizing the so-called "Great German" party, and was selected as one of the representatives of their views at Vienna. Warmly supporting the customs union (Zollverein), he acted in 1851 as one of its commissioners at the great industrial exhibition at London, and published an elaborate report on the woollen goods. Three years later he was president of the committee of judges at the similar exhibition at Munich, and the report of its proceedings was drawn up by him. In 1855 he became councillor of state (Staatsrath im ordentlichen Dienst), the highest honour in the service to which he could attain.

It is hardly surprising that in the midst of such varied and weighty practical occupations Hermann did not find time for carrying on systematically his work in the pure science of economics. Yet the long series of reviews, mainly of works on economical subjects, published in the *Münchener Gelehrte Anzeigen* from 1835 to 1847, attest his unabated industry and constant interest in the subject on its theoretical side, while his more elaborate papers in *Rau's Archiv der politischen Oekonomie* and in the *Augsburger Allgemeine Zeitung* show the wide extent of his practical knowledge. As head of the bureau of statistics he published a series of annual reports (*Beiträge zur Statistik des Königreichs Bayern*, Heft 1-17, 1850-1867) which are of very high value, especially as regards the growth of population. His only complete work in economic science, the *Researches*, had gone out of print a very few years after the book was published, but not until near the close of his life did Hermann find an opportunity of undertaking a revision of it. Upon this task he was engaged at the time of his death, 23d November 1868, and he had revised, enlarged, and amended nearly two-thirds of the volume. The second edition, prepared from his MS., and including those parts of the first edition which had not been revised or superseded, was published in 1870 by his friends Dr Helferich and Dr Mayr. There have since been several

reprints. Although the *Staatswirthschaftliche Untersuchungen* is not a systematic treatise on political economy, it must nevertheless be regarded as in many respects the most important contribution to the science since the *Wealth of Nations*. It cannot, indeed, be said to contain principles which are in themselves novel or original; Hermann's merits are not so much those of a discoverer as of a most acute and subtle critic. Like Ricardo he excels in abstract analysis, in resolution of complex phenomena into their simpler elements, but he has a more firm hold than Ricardo ever seems to have possessed of the true nature of these elementary facts, and a remarkable power of precisely stating and comprehensively combining them. The peculiar value of the *Researches* consists in the strict analysis to which the primary notions of economics are subjected, in the general conception of the method and plan of the science which emerges from this analysis, and in the masterly way in which fundamental principles are carried out in the detailed problems of the science. Only in the fashion indicated by Hermann can we hope to render clear the position of a pure theory of economic facts as an indispensable and independent branch of social science. The historic method of inquiry, fatal to much that has been regarded as distinctive of the abstract or English school of political economy, harmonizes perfectly with the theory of the elementary facts from which economical development takes its start, as stated by Hermann and those Continental writers who have followed him.

The *Researches*, in the 2d edition, consists of ten separate essays, of which the first, on the fundamental notions of economics ("Grundlegung," pp. 1-77), the fifth (pp. 149-389, on "Production"), the sixth (pp. 390-459, on "Price"), the eighth (pp. 448-531, on "Profit"), and the ninth (pp. 582-598, on "Revenue") are of the greatest importance. In the "Grundlegung," a clear and lucid description is given of the simple phenomena, in family, community, and state, upon which economical inquiries are founded. Human wants and the satisfaction to be obtained for them by labour exercised on natural agents are recognized as the primitive facts. But in the satisfaction of wants there are two aspects, the technical and the economical. Technically we consider solely the process by which commodities of a quality suited to satisfy want are obtained. Economically we have always to estimate the ratio between the effort expended and the result obtained. An "economy" is a distribution of forces so that the result, satisfaction, may be obtained with least expenditure of effort, with least loss of utility. The influence of this economical principle, the institutions to which it gives rise, the conditions under which it is possible, and the circumstances which affect, modify, or counteract it, are traced with reference to the individual, the family, the community, and the state or nation. The increasing complexity of the phenomena does not alter the nature of the principle which lies at the basis of them, and it is the business of economic theory to analyse these phenomena under guidance of the general principle. Economics is therefore defined by Hermann as the "quantitative theory of goods;" and, though he is sparing in the use of symbols, his method of treatment is throughout mathematical. Deserving of attention is the manner in which he points out the influence of collective feeling and collective wants as giving rise to special institutions (government, defence) in the community. To this first fundamental essay the three succeeding papers ("Wants," "Goods," "Economy," pp. 78-142) are appendices. The treatment of these, the classifications given, the detailed discussion of particular points, e.g., the productivity of labour, and the distinction drawn between economical estimates from the individual or the collective point of view, make up a solid contribution to the science.

The fifth essay is an elaborate treatise on the theory of production, treating the agents of production—free goods, labour, and capital—separately, then the interests of the several parties engaged, and the changes due to variations in the cost of producing. Under "Labour" is given the most complete and systematic discussion of separation of employments. Capital is defined so as to include land, but careful reference is made to the distinctive peculiarities of this form of wealth. Especially remarkable is Hermann's treatment of what he calls *Nutz-capital* (i.e., service-capital), with regard to which he accepts almost entirely the view of J. B. Say. Under fixed capital a very elaborate treatment of the nature and economic influence of machines is given, while the handling of changes in the cost of production, both here and in the essay on "Profit," is acute and luminous.

The sixth essay analyses the forces which underlie supply and demand. These are stated to be:—(a) on the side of the purchaser—(1) his desire for the commodity in question, or its utility to him, (2) his means, (3) the competition of sellers; (b) on the side of the seller—(1) cost of production, (2) competition of the buyers, (3) the value of the medium of exchange. The same considerations are shown to hold good in the case of the price of labour, though unfortunately the seventh essay, on "Wages," is incomplete. The eighth essay, on "Profit," discusses very elaborately the rate of return on the various species of capital and the circumstances that determine it, distinguishes interest from profit in general, and marks as a special form the profit of the *entrepreneur* (*Unternehmergewinn*). This last he regards as distinct from wages.

superintendence, and from insurance for risk. The ninth and tenth essays, on "Revenue" and "Consumption," are perhaps specially interesting from the clear mode in which the theory, afterwards called that of the wages fund, is rejected, and from the precision with which the diverse points of view for estimating net revenue are discriminated.

This brief analysis is sufficient to show the high value of Hermann's work as a contribution to pure economics. On practical questions, those of economic legislation, his opinions are only to be gathered with difficulty from the papers in the *Gelchrte Anzeiger*, and generally were expressed with such reference to special circumstances as to render doubtful their full import. It seems probable, however, that his views on protection were far from clear, and that he was somewhat under the sway of the dangerous principle that the best financial policy is encouragement of national industry. It is difficult, however, to speak definitely on this subject.

See Kautz, *Oesch. Entwicklung d. National-Oekonomie*, pp. 633-38; Roscher, *Oesch. d. Nat. Oekon. in Deutschland*, pp. 860-69.

HERMANN, JOHANN GOTTFRIED JAKOB (1772-1848), classical editor and philologist, was born at Leipsic on November 28, 1772. Entering the university of his native city at the precocious age of fourteen, Hermann at first studied law, but his inclination to classical learning was too strong to be resisted, and accordingly, after a session spent at Jena in 1793-94, he became a lecturer on classical literature in Leipsic. In 1798 he was appointed professor extraordinarius of philosophy at the university there, and after refusing an invitation to proceed to Kiel as rector of a school, he was in 1803 chosen professor of eloquence. In 1809 he received the chair of poetry in addition. He died, senior of the university, on December 31, 1848.

Hermann devoted his early attention to the classical poetical metres, and published on that subject *De metris Græcorum et Romanorum poetarum*, in 1796; *Handbuch der Metrik*, in 1798; *Elementa doctrinæ metricæ*, in 1816, of which an *Epitome* appeared in 1818; and *De Metris Pindari* in 1817, attached to Heyne's edition of that author. Of his influential and valuable writings on Greek grammar the chief are *De emendanda ratione Græcæ grammaticæ*, 1801; *Notes and Excursus to Viger's "De præcipuis Græcæ dictionis idiotismis,"* 1802; and *De particula & libri IV.*, 1831. His *Lexicon of Pholius* appeared in 1808. His editions of the classics comprise several of the plays of Euripides (see vol. viii. p. 680); the *Clouds* of Aristophanes, 1799; *Trinummus* of Plautus, 1800; *Poetics* of Aristotle, 1802; *Hymns* of Orpheus, 1805; and the *Homeric Hymns*, 1816. In 1825 Hermann finished the edition of Sophocles begun by Erfurdt. His editions of Bion and Moschus were published posthumously in 1849, and of all the plays of Æschylus in 1852. The *Opuscula*, a collection of Hermann's smaller writings in Latin, appeared in seven volumes between 1827 and 1877.

HERMANN, KARL FRIEDRICH (1804-1856), one of the leading representatives of classical investigation in Germany, was born August 4, 1804, at Frankfort-on-the-Main. His early education was received partly at Frankfort and partly at Weilburg, and his university studies were carried on at Heidelberg and Leipsic. On his return from a tour in Italy he habilitated in 1826 as privat-docent in Heidelberg; in 1832 he was called to Marburg as professor ordinarius of classical literature; and in 1842 he was transferred to Göttingen to fill the chair left vacant by the death of Otfried Müller. Both at Marburg and Göttingen he likewise held the office of director of the philological seminary. He died at Göttingen on the 8th of January 1856. Hermann's scholarship took in a wide and ever-widening horizon; but his vision was clear and steady, and he knew well how to portray for other eyes the scenes that shaped themselves with new life before his own. Among his more important publications are the *Lehrbuch der griechischen Antiquitäten*, of which the first portion (Heidelberg, 1841) deals with political, the second (1846) with religious, and the third (1852) with domestic antiquities; the *Geschichte und System der Platonischen Philosophie* (Heidelberg, 1839); an edition of the Platonic Dialogues (6 vols., Leipsic, 1851-52); and *Culturgeschichte der Griechen und Römer* (Göttingen, 1857-58, 2 vols.), published after his death by G. Schmidt. A collection of *Abhandlungen und Beiträge zur class. Literatur und Alterthumskunde* appeared in 1849, but the great mass of his essays and brochures,

which deal with a vast variety of archæological, artistic, critical, and philosophical subjects, are still unarranged. See Leclner, *Zur Erinnerung an K. F. Hermann* (Berlin, 1864).

HERMANNSTADT (Hungarian *Nagy-Szeben*, Latin *Cibinium*), chief town of an Hungarian county of the same name, is advantageously situated on the Szeben, an affluent of the Aluta, about 72 miles S.E. of Kolozsvár (Klausenburg), and is the terminus of the Kapus and Nagy-Szeben branch line of railway, in 45° 48' N. lat. and 24° 9' E. long. It is the see of a Greek Orthodox bishop, the meeting place of the Lutheran consistory for the Transylvanian circle, and the headquarters both of the honvéd (or "defence-militia") and of the regular infantry and artillery of the district; and it also possesses royal courts of law and assizes, and offices of finance, assay, state survey, and engineering. Hermannstadt has a somewhat mediæval appearance, the streets being often narrow, and the houses built in the old German style. Of the squares the most striking is the large quadrangular market-place. The public buildings comprise Roman and Greek Catholic, Greek Orthodox, Calvinist, and Lutheran churches, a royal law academy, both Roman Catholic and Lutheran gymnasia, a Greek Orthodox seminary for priests, a hospital for the insane, foundling and orphan homes, Franciscan and Ursulan retreats, a house of correction, civil and military hospitals, county and town halls, the infantry and large new artillery barracks, the town theatre, the "Transylvania" assurance office, the "Albina" bank, and, above all, the Bruckenthal palace with its fine museum and library. Among the industrial establishments are factories for the preparation of soap, candles, soda, sulphuric acid, bone-dust, paper, cloth, linen, leather, caps, boots, combs, and building materials. There are also printing houses, tanneries, and rope-walks, several distilleries, and a large brewery. A brisk trade is carried on both at the regular weekly markets and at the special fairs. The civil population in 1870 was 18,998, of whom about two-thirds were of German (Saxon) and the remainder of Roumanian and Magyar extraction.

The German name of the town is traceable to Hermann, a citizen of Nuremberg, who about the middle of the 12th century established a colony on the spot. In the 13th century it bore the name of *Villa Hermannii*. Under the last monarchs of the native Magyar dynasty Hermannstadt enjoyed exceptional privileges, and soon became a thriving centre of trade, its commerce with the East rising to considerable importance. In the course of the 15th and 16th centuries it was several times besieged by the Turks. In 1610 it suffered at the hands of the Transylvanian prince Gabriel Bathori. At the beginning of 1849 it was the scene of several engagements between the Austrians and Hungarians; and later in the year it was several times taken and retaken by the Russians and Hungarians, the latter being eventually forced to yield to overwhelming numbers, August 6.

HERMAS. See APOSTOLIC FATHERS, vol. ii. p. 197.

HERMENEUTICS, BIBLICAL, is that branch of theological science which treats of the principles of Scripture interpretation. Various descriptions of the theory of the discovery and communication of the thoughts of Holy Scripture (Lange), the science of attaining clearness both in comprehending and in explaining the sense of the Biblical authors (Ernesti), the methodological preparation for the interpreter and for exegesis (Doedes), the science of the removal of differences between us and the sacred writers (Immer), it has for its task to determine the laws of valid exegetical practice. Schleiermacher and Klausen have limited it to the doctrine of what the interpreter has to observe in order to put himself in possession of the mind of Scripture. The former defines it as a discipline which looks simply to the reader's own apprehension, not to the conveyance of the meaning ascertained to others; which latter is to be regarded, he thinks, as but a particular division of the art of speaking and writing. It has been

generally taken, however, to have respect to the communication as well as the acquisition of the thoughts of the Biblical writers. This larger definition, which is as ancient at least as Augustine's statement of the two things "quibus nititur omnis tractatio Scripturæ, modus inveniendi quæ intelligenda sunt et modus proferendi quæ intellecta sunt" (*De Doctr. Christ.*, i. 1), has been formally accepted or practically acted on by most modern authorities. It is consonant with the currency of the terms ἑρμηνεύω, ἑρμηνεύς, ἑρμηνευτής (connected it may be with *Hermes*, but not derived from that, such use of a deity's name being probably unexampled).¹ These in the classics express both expounding (Pindar, *O.*, 2, 153) and interpreting or translating a foreign language to others (Xen., *Anab.*, i. 2, 17; Herod., ii. 125); while in the New Testament ἑρμηνεύειν means to translate (John i. 39, 43) and διερμηνεύειν to expound, interpret, or translate (Luke xxiv. 27, 1 Cor. xii. 30, Acts ix. 36). The definition is in harmony too with the Protestant idea of exegesis as an art which brings the contents of Scripture to the general understanding, and the Protestant conception of the direct approach of God's word to man's heart by Scripture. As the theory of the interpretative art hermeneutics is usually taken to be an historical science, forming a subdivision of historical theology. Where, however, a fourfold, instead of a threefold, distribution of theological science is adopted, it is assigned to literary theology. It presupposes such disciplines as textual criticism and Biblical introduction, while it may exercise a reflex influence on some of the discussions with which these are conversant. Although practice precedes theory, and only through the use of the art of interpretation can the principles of interpretation be reached, as it is out of Scripture itself that the laws of Scriptural exposition must be drawn, theoretically this science precedes exegesis and forms an indispensable preparation for Biblical theology. Much which it has been the custom to embrace within it belongs really to general hermeneutics. The limits properly assignable to it are comparatively narrow, its immediate object being to decide how the laws of general hermeneutics are related to the particular records known as Scripture. The propriety of a special Biblical hermeneutic is established so far as Scripture is proved to be more than an ordinary literature. The Christian who comes to the Bible with the conviction that it is the record of divine communications, and with the experience that it is the medium through which God has spoken to him and led him into new relations to Himself, has to ask whether the principles of ordinary hermeneutics have to be modified or supplemented when applied to these books. Neither the Christian recognition of the spiritual character of Scripture nor the Protestant assertion of the right of private judgment, the perspicuity of Scripture, and the laity's direct interest in the Bible, warrants the extreme position assumed among some sects, that a scholarly interpretation and, therefore, a science of hermeneutics are superfluous. Being a literary record composed in languages which demand the exegetical *praxis* of translation, and produced under circumstances, by writers, and for readers widely removed in date and character from our present acquaintance, Scripture requires a scientific process for its exposition, and the laws of that process must be verified. The peculiar value which attaches to it as a holy literature makes this the more needful, the exceptional position assigned it rendering its interpretation open to the invasion of prepossession and private religious ideas. The exclusive authority ascribed to these books by the Protestant, who accepts them as the only rule of faith and life, gives him a special interest in hermeneutics. The concrete and historical form in which their spiritual teaching appears, the figurative, typical, and symbolical terms

so largely used in them, the numerous presuppositions on which their statements of religious truth and fact proceed, suggest the necessity of such a discipline. The qualities of Scripture which render its appeal to the common understanding distinct and immediate are arguments for scientific intelligence in educing from its declarations nothing more and nothing less than their exact intention. The interpreter's function being, not to develop some meaning which the words might bear to present students or which the first readers may have seen in them, but simply to ascertain with precision and completeness the ideas which the writers themselves meant to convey, it may be said with Schleiermacher that in a certain sense the interpreter has to educe more than the author introduced. The former has to bring out into clearness much that influenced the latter half-unconsciously in his composition, and to give objective expression to much that underlies his definite statements. Hence the special need for a scientific hermeneutic in the case of a book like the Bible, in which there is so much that is implicit. The vast variety of results reached in crucial passages, and the wide diversities of method which have been pursued among individual exegetes and in exegetical schools, make the propriety and utility of such a science the more apparent.

Since Christopher Wolle (*Hermeneutica Novi Fœderis acroamatio-dogmatica certissimis defecate philosophiæ principii corroborata eximisque omnium Theologiæ Christianæ partium usibus inserviens*, Leipsic, 1736) the hermeneutics of the New Testament, for the sake of convenience or on grounds of scientific distinction, has often been separated from the hermeneutics of the Old Testament. The scientific union or disjunction of these disciplines depends on the view entertained of the mutual relations of the Hebrew Scriptures and the Christian. Where the Bible is seen to constitute an organic whole, the hermeneutical principles applicable to the two Testaments are treated in connexion. It then becomes one great object of the science to grasp the differences which are discovered within the unity of Scripture, and exhibit what account has to be taken of these in the art of interpretation. A distinct position, however, naturally belongs to Jewish hermeneutics, which dealt with the Hebrew Scriptures as at once the entire written revelation of God, and the repertory of the highest wisdom on all subjects of human inquiry. The results of the scientific study of the Old Testament, which was carried on with vast activity from Ezra's time by numerous scribes and in great schools and colleges (Jerusalem, Tiberias, Sura, Pumbeditha, Nabadia, &c.), are seen in the Talmudical writings, the *Mishna* giving authoritative enlargements and explanations of the law, and the *Gemara*, in its twofold form of *Jerusalem Talmud* edited at Tiberias, and *Babylonian Talmud* proceeding from Sura, containing further commentaries, fantastic definitions, and explanations of prior explanations (see *TALMUD*). The most ancient Jewish interpretation of Scripture, the *Midrash* ("study," "investigation"), which assumed a fixed character during the period of the second temple and gradually formed a literature, ran out into two great branches, logical or legal exposition, and practical or homiletical exposition. The former, designated "Halacha" ("rule by which to walk," "binding precept"), brought the law to bear upon points of religious or general interest on which there was no explicit declaration. It confined itself chiefly to the Pentateuch, extracting from it by numerous exegetical expedients a body of "Halachoth" or sopheric precepts (cf. Matt. xv. 2, Mark vii. 3), which were held authoritative. These, after a long period of oral transmission, gradually assumed written form, and passed finally through a process of compilation, classification, and redaction which extended perhaps from about two centuries before to two centuries after Christ. The latter,

¹ See article *HERMES*, and compare Curtius, *Greek Etymology*, § 350.

styled "Hagada" ("opinion," "free exposition"), was meant for edification, traversed the entire Old Testament, and occupied itself with the application of Scripture to the purposes of practical instruction in all manner of subjects, ethical, political, metaphysical, theosophic, as well as religious. Its expositions were conveyed in forms, symbolical, poetic, parabolic, such as were most likely to arrest attention, and, though of no binding authority, it made itself so attractive to the people that it was often known as "the Midrash" distinctively. The hermeneutical laws followed in these two lines of exposition are sufficiently well known. Eliezer ben Jose, the Galilæan, a distinguished rabbi of the 2d century of our era, has embodied the results of a final redaction of the principles of the Hagadic exegesis in a series of thirty-two rules. Some of these are sound, dealing, *e.g.*, with the use of brachylogy, repetition, parable, the reconciliation of two discrepant texts by a third, &c. Many of them are wholly fantastic, prescribing how explanations are to be sought by reducing the letters of a word to their numerical value, by the transposition of letters, by the substitution of another word of the same numerical value for one which yields no worthy sense, by studying the introduction of superfluous particles, &c. Such principles held a much smaller place in the Halachic exegesis, which, as it aimed at something higher than applications of Scripture, could indulge in fewer freedoms in certain directions, so far as it was true to its idea. In the fixing of the Halachic hermeneutics Hillel I. (died 8 or 10 A.D.) occupies a conspicuous place. He reduced the traditional legal erudition of the Jews, with its bewildering multiplicity of laws, from the 600 or 700 sections over which it is said previously to have spread, to six capital "Sedarim" or orders, forming a manageable basis on which his successors 'Akiba, Simon III., and Jehudah I. could work on to the final codification of the *Mishna*. He was also the first to formulate definite rules by which the rabbinical development of the law should proceed. These canons of interpretation were seven in number, afterwards increased by Rabbi Ismael to thirteen by the addition of seven new rules and the omission of the sixth, and looked to the construction of Biblical warrant for precepts which it was wished to prove implicit in the law. These "Midloth" were instructions to reason (1) *a minori ad majus*, (2) *ex analogia*, (3) by derivation of a principal proposition from a single passage, (4) by derivation of a principal proposition from two passages, (5) by limitation of the general through the particular, (6) by explanation of one passage through another, (7) by the use of the context. The idea that the Old Testament, pre-eminently the law, held hidden in it the highest wisdom on all subjects, was naturally inimical to the rights of the literal sense. The rabbinical hermeneutics drew inevitable distinctions between the proper or innate sense (משמעות), which again was described as either verbal (מקרא) or figurative (מדרש), and the derivative or studied sense (מדרש, מדרש), which was to be sought either by inference (מדרש) or by artificial conjunction (מדרש). The natural sense, however, though practically robbed of its dues, was not professedly ignored. This regard for it, which was never wholly disowned, ultimately took shape in the improved rabbinical hermeneutics of the Middle Ages. In the writings of such rabbis as Saadiah Gaon, Jarchi, Rashi, Kimchi, Maimonides, Abarbanel (a line of expositors extending from the 10th to the 16th century), we find, alongside the traditional rules and explanations, a scientific recognition of the interpreter's duty to give the literal sense as well as a practical application of the principles of grammatical and historical exegesis to the Old Testament.

The hermeneutics developed among the Hellenistic Jews had marked characteristics of its own. These interpreters, departing from the exclusiveness of rabbinical devotion to

the Old Testament revelation, and from the pure Hæbraism of native Jews, brought to the study of the sacred books a range of ideas derived from Hellenic culture. They had to devise a hermeneutical procedure which would harmonize their new ethnic learning with the traditional estimate of the Jewish Scriptures. To the theosophic Hellenist, and specially to the Alexandrian Jew, acceptance of the plain sense was often an impossibility. A reconciliation was sought by the use of allegorical interpretation. This method was also pursued by the Rabbinical exegetes. It is embraced in the Halachic hermeneutics, and is seen in the distinctions drawn by Palestinian Jews between the body and the soul of texts. But while the allegorical interpretation of native Jews, in consonance with their purer estimate of the Hebrew revelation, moved in the direction of the typical, that of the Hellenists became rather mystical. The coryphæus in this hermeneutical practice was Philo (born perhaps about 20 B.C.), although he had predecessors in Aristobulus (180 B.C.), Josephus, and others. He devoted himself mainly to the exposition of the Pentateuch, with the view of explaining the realism and anthropomorphism of the Old Testament in a way to suit the philosophy of the time. Wishful to retain the Alexandrian Jew's regard for Moses as the supremely inspired prophet of God and the oracle of all mysteries along with adherence to the current Platonism and theosophy, he supposed that the Mosaic writings contained a twofold mode of teaching, a popular representation of God and divine things and a spiritual. It was the task of wisdom to penetrate through the envelope of the literal history to the secret sense which it shielded. The verbal sense was acknowledged, but held to be for the illiterate. The outstanding facts in the records of the creation, the deluge, the careers of the patriarchs and Moses, were accepted in an historic sense, but the details of all these narratives were spiritualized. Sometimes the figurative meaning was made the only meaning, but in other cases the objective meaning was allowed to be the intended meaning. The hermeneutical rule, however, was to rise by allegory from the superficial anthropomorphic sense (τὸ ψυχικόν) to the higher or spiritual sense (τὸ πνευματικόν). The simple histories were symbols of abstract truths. To the enlightened they were so many modes of soul (τρόποι ψυχῆς)—Adam the figure of the sensuous nature, Rebecca of patience, Leah of despised virtue, Egypt an emblem of the body, and Canaan of piety.

Two later chapters in the history of Jewish hermeneutics deserve notice. On the one hand the rabbinical procedure was decisively departed from by the Karaites, among whom Japhet ben Heli, of Bussorah, belonging to the close of the 10th century, and Aaron ben Joseph, of the 13th century, are notable. In their case interpretation again sought the *via media* between bald literalism and arbitrary spiritualizing. It was prosecuted on the principles of renouncing the quest after a variety of senses, abiding by the natural sense, accepting metaphor where the figurative was intended, and conserving the religious interest. On the other hand an extraordinary development was given to the rabbinical hermeneutics by the Kabbalists of the Middle Ages, who used the devices of artificial interpretation in order to find an Old Testament basis for their mixed Neo-Platonist, Gnostic, and Sabæan culture. The Kabbala ("what has been received," "tradition," see KABBALA) had its roots in the ancient doctrine of numbers, for which the Jews were probably indebted to the Chaldeans. The use of the numerical power of letters as a key to mysteries, which the Palestinian Jews had early favoured and which formed a not inconsiderable element in the Hagadic exposition, expanded into a vast system of fantastic Hebrew Gnosticism in the 8th century of the Christian era. The written Word was regarded as a depository of secret doctrine

and absolute truth which could be entered only by the initiated. The mysteries hidden in its letters required for their discovery processes of exchange, more or less intricate, between literal and numerical values. By the combinations and permutations of letters, the interchange of words of equal numerical value, and similar artifices, new meanings were extracted where the proper sense seemed poor, and acceptable meanings found where offence was felt. Where the text, *e.g.*, states (Numbers xii. 1) that Moses married an Ethiopian woman, the veiled sense was shown to be that he married a woman of *beautiful countenance*, and the offence against the law was thus removed. For the letters of מִשֵׁיִת added together make the sum 736; the letters in the expression מִשֵׁיִת מִשֵׁיִת, "beautiful of countenance," yield the same sum; and the enlightened are able to read the latter idea in the former appellative. Distinct titles came to be applied to different branches of the art. The process of reaching hidden truths by the numerical equivalence of letters (as when from the circumstance that κ occurs six times in the first and last verses of the Old Testament it is inferred that the world is to last 6000 years) was styled "Gematria." The process of forming new words out of the several letters of some solemn term, or one new word by combining the first letters of several words (as when the answer מִשֵׁיִת, "circumcision," is discovered in the question in Deut. xxx. 12, "Who shall go up for us to heaven?") by bringing together the letters with which the several words in the query commence, was called "Notarikon." The use of the anagram or permutation (as when by transposition of מִשֵׁיִת into מִשֵׁיִת it is ascertained that "mine angel" of Exod. xxiii. 23 was the angel Michael) was known as "Temurah." The hermeneutical practice of the Kabbalists increased in subtlety as the theosophic system itself grew. Rules were elaborated for exchanging the powers of letters, reading them in a variety of orders, and otherwise conjuring with the literal sense.

The course which Biblical hermeneutics has run outside the purely Jewish pale has been not less changeful or remarkable. The New Testament writings show at large how the apostles and first followers of Christ viewed, interpreted, and quoted the Old Testament. They give little in the shape of formal hermeneutical principles, but allow much to be inferred from usage and example. Conclusions as to authoritative canons of interpretation, so far as these are drawn from New Testament employments of Old Testament Scripture, are weighted with the question whether or how far currency is followed. It is affirmed on the one hand that Paul, *e.g.*, in his hermeneutics, was a pure rabbinist, while on the other the equally extreme position is held that his training is in no way reflected in his use of the Hebrew Scriptures. The citation of the Old Testament in the New, which forms a question by itself and one of great intricacy, takes a variety of modes. Passages are reproduced as direct prophecies of the Messiah and His kingdom (Acts ii. 34, Heb. i. 13), as mediate references to the same through partial realizations of their idea (Heb. ii. 6-9, 12, 13), as illustrations or applications of principles common to both economies (Rom. x. 6-8, 1 Tim. v. 18), as apt expressions, without the character of explicit quotation, in which New Testament statements naturally embody themselves (1 Pet. i. 24). The proper and immediate sense is adhered to. The application of typology and symbolism (Heb. viii. 5, ix. 9) is at the same time exemplified, and the existence of secondary or higher meanings in allegorical or other forms (Gal. iv. 24, Eph. v. 32) is to a certain extent recognized. The typical relation of the Old Testament to the New is everywhere presented. It is exhibited both in the histories and in the institutions, and is developed alike in ethical, didactic, and prophetic significance (1 Cor. x. 6, 11, Rom. vi. 17, v.

14). The Hebrew revelation is interpreted as a divine preparation for the Christian and as a continuous prophecy bearing onwards towards Christ (Acts. ii. 25). Its official personages and its saints, its ordinances and its events, are real though imperfect exhibitions of Messiah and the Messianic kingdom. Even its minor occurrences and incidental utterances are anticipations or expressions of the purposes of Jehovah realized in the Christian dispensation (Matt. ii. 15, Heb. iv. 7, Eph. iv. 8-12). How far Biblical hermeneutics within the Christian Church has gathered its principles from Scripture itself, and what use it has made of the New Testament *praxis* will appear from its history. It will be enough here to deal with the capital ideas to which the various conflicting methods seem capable of being reduced. We indicate which of these prevailed on the whole in important schools and periods, without attempting a chronological statement or detailing the exact relations of each great name to this subject. It is not to be supposed, however, that any single mode was exclusively dominant at any one time, or that the interpreters whose names are connected with some particular procedure held by that only. On the contrary, in the long-continued absence of a definite settlement of principles the best writers swayed remarkably from method to method, and men who are largely identified with vicious modes exhibit at the same time admirable examples of the opposite. It may be said that three great hermeneutical tendencies have been followed. These may be conveniently designated the subjective, the dependent, the historical.

1. The first, which we have distinguished as the *Subjective* tendency, embraces all those widely diverse schemes which agree in passing beyond the objective intention of the words and seeking veiled or underlying meanings. To this belong the different forms of the allegorical method, by which is meant the imposition of a sense not designed by the writer. It is the adding of a meaning foreign to the intention, rather than the substitution of an improper for the proper sense. The first Christian interpreters were under special temptations in this direction. The idea of the need of exceptional principles of exposition in order to reach the deep significance of divine communications had a great hold of the ancient mind, Greek, Roman, Oriental, and Hebrew. The spell of this idea and the powerful influence of the Rabbinical tradition, acting on the Christian conviction that the Bible is a divine message, readily induced the notion that the ordinary laws of interpretation are inadequate, and that Scripture is honoured when the natural or "lower" sense is made the stepping-stone to a "higher" sense for which special processes are required. Early Christian literature, although its mysticism may sometimes be otherwise explained, adheres decidedly to this idea. The apostolic fathers and the Apologists, while not entire strangers to sound spiritual interpretation, are addicted to the allegorical. The *Epistle of Barnabas* confirms faith and perfects *γνώσις* by spiritualizing the details of such narratives as that of the two goats in Leviticus xvi. The *Shepherd of Hermas* contains various examples. Clement of Rome gives the figurative application of the scarlet line suspended from Rahab's window, which is adopted by so many of the fathers. In this connexion great interest belongs to Justin Martyr, who exhibits acquaintance with several of the distinct senses which were subsequently formulated. Embracing Christianity as the only certain philosophy, and carrying much of his old Platonism with him into his new faith, he dealt with the Scriptures very much as he dealt with the classics. The histories of the Old Testament (he seldom expounds the New) were a drapery covering broad spiritual truths. As the piling of Pelion and Ossa was a Greek version of the building of the tower of Babel, so Jacob's marriage with Leah and Rachel denoted

Jehovah's revelation in the Jewish Church and the Christian. Every particular in prophetic passages like Gen. xlix. 9-12 had a mystical reference to Christ and His salvation, His passion being signified by the washing of the garments in wine, the Jews by the ass, the Gentiles by the colt.

The allegorical method, which offers itself as a natural expedient for harmonizing difficulties between religious faith and philosophical feeling, and which had been freely applied to Homer by Plato, found a most congenial home in Alexandria, where Philo's influence was strong. It became a recognized principle with the entire catechetical school, firmly rooted in the distinction which there prevailed between *πίστις* and *γνώσις*. Clement of Alexandria, who seems to have been the first to bring the New Testament no less than the Old under its scope, finds a parabolic meaning in all Scripture, and affirms that the literal sense carries us simply to the elementary stage of Christian knowledge called faith, while it is only through the allegorical or mystical interpretation that we can reach that higher wisdom which implies insight into the essence, reason, and real relations of faith's objects. He speaks of a "tradition of the church," an "ecclesiastical canon," or "canon of the truth," which gives the key to the true understanding of Scripture, and is identified with the *γνώσις* or spiritual apprehension of divine mysteries as that was first communicated by Christ to the apostles in oral form, and by them transmitted to their successors. This canon is described as "the consent and harmony of the law and the prophets with the covenant delivered during the Lord's presence." In accordance with this Clement discovers in the Mosaic law three senses in addition to the natural. The terms in which the precepts are expressed are images of other things, rules for the direction of life, and predictions of the future. The high priest's robe is an emblem of the world of sense; the bells upon it are a symbol of the acceptable year of the Lord. The decalogue itself is spiritualized, the fifth commandment being taken to refer to the Heavenly Father, and that divine Wisdom which is the mother of the just.¹

A position of commanding importance must be claimed for Origen, whose genius secured wide and long-continued acceptance for his greatest extravagances. Exact grammatical exegesis is by no means alien to his homilies and commentaries, and many of his strangest uses of Scripture may be viewed as practical applications rather than scholarly expositions. Fanciful modes, however, are so predominant that he has been generally regarded as the chief allegorist of the Christian Church. Yet the disservice thus done by his example cannot cloud the lustre of his merits in Biblical studies. His Platonism, his adhesion to the Alexandrian idea of *γνώσις*, his wish to defend and elucidate the Christian religion by reason and philosophy, his exaggerated notion of inspiration, combined to commend a mystical style of interpretation. In terms of the Platonic division of man into body, soul, and spirit, he held that Scripture had a threefold sense, *σωματικός, ψυχικός, πνευματικός*. The first, or obvious, sense was meant for the edification of the simple. The second, which was to be sought for under the letter, and embodied the soul of Scripture, exhibited the bearing of the word upon the practical needs of the moral life, and addressed itself to the more advanced. The third, which lay still deeper, and imparted the spirit of Scripture, disclosed pure unmixed truth, exercised the speculative powers, and was intended only for the perfect, such as are described in I Cor. ii. 6, 7. He has been sometimes credited with the promulgation of the fourfold distinction afterwards so current, especially in the Latin Church, and expressed in the couplet (given, *e.g.*, by Lyra):—

Litera gesta docet, quid credas allegoria,
Moralis quid agas, quo tendas anagogia.

Such terms, however, as tropological, mystical, allegorical, pneumatic, anagogical, are rather interchangeable with him. The literal sense, too, is so far from being dispensed with that he has even been regarded (*e.g.*, by Ernesti) as the first who secured for it its primary value, particularly in New Testament exegesis. But, while he maintains that the spirit and the letter are generally to be taken together, and admits that no small portion of the contents of Scripture (*e.g.*, the decalogue, precepts of universal obligation, even many of the narratives) may not be allegorized, his practice is greatly in the direction of esteeming the literal sense only as the protecting shell of secret treasure. Wherever the letter yields a meaning which seems to him unworthy, or opposed to reason and possibility, a mystical sense is discovered. He stumbles at the record of creation when it introduces the sun after the third day, at many of the Mosaic ordinances, at the realism of Christ's temptation. He finds mysteries or figures of spiritual things in Eden, Abraham's wives, Rebecca's visit to the well, the waterpots at Cana, and many other narratives. The later type of Alexandrian hermeneutics is seen in Cyril, who, without wholly abandoning the literal sense, carries typical interpretation into unqualified allegorical extremes in dogmatic and polemic interests.

The Western Church exhibited the same tendency, not only in the marked artificialities of such teachers as Hippolytus, Hilary, and Ambrose, but in the eminent instance of Augustine. Though not the first to attempt a statement of hermeneutical canons (having before him, for instance, the seven rules of Tichonius, which he states and criticizes at length), he constructed more of a system in this line of inquiry as in some others. Many of the principles which are enunciated in different parts of his writings, and most definitely in his *De Doctrina Christiana*, are of permanent value. He conceives the object of interpretation to be the discovery of the thoughts of the writer exactly as he meant to express them. He shows that the real sense is often not to be got by insisting merely on expressions as they stand by themselves; that they must be compared with the immediate context, with similar passages elsewhere, and with the essentials of Christian doctrine; that faith and the aids of the Holy Spirit cannot supersede the use of science; that a reverent and sympathetic mind is indispensable. But along with such rules as these he propounds others which served as grounds for his allegorical procedure. He affirms, *e.g.*, that whatever cannot clearly be seen to bear upon honesty of morals or the truth of faith must be taken figuratively. He speaks of several different modes of interpretation,—the historical, the aetiological, the analogical, the allegorical. He usually practises the first and the last of these. His profound spiritual experience gave him a truer insight than his canons indicated into many parts of Scripture, and above all into the Pauline epistles. Yet over most even of the New Testament he allows the allegorical fancy to range freely. His influence perpetuated the reign of the allegorical method for many centuries throughout the Western Church. In Gregory the Great, the Venerable Bede, Hrabanus Maurus, Hugo de S. Caro, and many others, we see it steadily extending rather than merely maintaining its sway, until in Bonaventura we find the current four senses—historical, tropological, allegorical, anagogical—enlarged to seven by the addition of the symbolical, synecdochical, and hyperbolical.

2. The second great hermeneutical tendency, which we call the *Dependent*, has an equally instructive history. It is easy to understand how extreme allegorizing would lead to a counter movement, and how this would be helped by the exigencies of dealing with heretics who were themselves

¹ See especially *Strom.*, vi. p. 676-89; also Baur, *Die Christliche Gnosis*, and Kaye, *Some Account of the Writings and Opinions of Clement of Alexandria*.

advocates of *γνώσις*. The appeal soon came to be made to a rule of faith which may at first have meant nothing more than the harmony of Scripture teaching, but which was speedily identified with something outside Scripture, with the contents of doctrinal summaries, or with the verdict of exegetical tradition. The East and the West gave way alike to this bias, but the West first and most positively. In both we find early mention of an ecclesiastical canon or norm of truth. In the Church of the East, indeed, that took originally the form of an authoritative *γνώσις* or private exposition of the esoteric meaning of Scripture handed down by careful tradition from Christ and the apostles, while in the Church of the West it was rather the voice of the church itself, and that soon the voice as formulated. Both churches, however, more or less distinctly recognized an ecclesiastical tradition represented in compends of doctrine which were used for catechetical and other purposes, and an interpretative tradition embodied in the expositions of influential doctors. Thus hermeneutical independence was sacrificed. In Irenæus and Tertullian we see how a very natural reaction took this direction. The necessity of meeting errorists who were greater adepts in arbitrary spiritualizing than any whom the church could present led them to protest against the practice. They saw the propriety of looking to Scripture itself for hermeneutical guidance, and of rescuing it from the despotism of a mystical philosophy which threatened the life of its cardinal doctrines. They adopted a simpler reading of its message, and so far they deserve the name of pioneers in real historical interpretation. But, as appears in their gross chiliastic expositions, their literalism was carried to excess. It came into conflict with the deeper declarations of Scripture, and this conflict they were tempted to compose by a relapse into fanciful methods. It created difficulties in their controversy with Gnostic opponents, and these they thought to remove by a final appeal to an authoritative tradition fixing the sense in which the sacred books which both parties used as witnesses to their doctrine were to be understood. This was to be found in its integrity in those ancient churches which had enjoyed direct apostolic teaching, and, as Irenæus conceived, in some special way in that of Rome. Gradually the idea of a normative analogy of faith discovered within Scripture was externalized, and the standard of interpretation was looked for in ecclesiastical symbols and the formal decisions of the heads of the church. In this process, which issued in the Tridentine definition of the ultimate determination of the interpretation of Scripture as resident in the church, and the more recent declaration of the infallibility of the pope as the voice of the church, Vincent of Lerins claims particular notice. In his *Commonitorium*, for which we are indebted to the Semi-Pelagian controversy, he lays down rules for the attainment of certitude in belief. Faith is to be settled by two things, the authority of Scripture and the tradition of the church. The former is a perfect and adequate foundation. Yet the caprices of interpretation require it to be supplemented by the latter. The sense of Scripture is the sense in which the church understands it, and this tradition of the Catholic Church, which is to be accepted as the canon of hermeneutics, is defined as "quod ubique, quod semper, quod ab omnibus creditum est." This treatise, still retained in singular honour by large sections of the Christian Church, exhibits the hermeneutics which had been winning acceptance since the times of Irenæus and Cyprian, and by which the Latin communion was led to bind itself. The result of the deference paid to the fathers in both churches, and especially in the West, was the renunciation of independent exegesis and the production of compilations of patristic comments. These *συναί* or *Catena* epitomized the interpretations of most of the great expositors, particularly Origen, Chrysostom,

Jerome, and Augustine, and were on the whole more successfully executed in the Greek Church than in the Latin. They were in use by the end of the 5th or beginning of the 6th century. Andreas of Cæsarea, who belongs to the former period, or Olympiodorus, whose date is about the beginning of the 7th century, has sometimes been recognized as the earliest epitomizer; but the position is to be assigned rather to Procopius of Gaza, who comes between these two. For many centuries the most eminent divines took part in the preparation of *Catena*, such as Cassiodorus (also a literalist), Bede (already cited as an allegorist), Alcuin, Hrabanus Maurus (often honoured as the most learned interpreter of the 8th and 9th centuries), Haymo, Remigius, Sedulius, Theophylact, Ecumenius, Paschasius Radbertus, and Aquinas. The *Catena aurea* of Aquinas on the gospels was of great value. Redactions of the *Catena* were also made in course of time. These were the *Glossæ*, which were known as *marginales* or *extrinsecæ* when the comments were given on the margin, and *interlineares* or *intrinsecæ* when these were introduced in the text. The most influential glossa of the second class was that of Anselm of Laon, who belongs to the end of the 11th and the beginning of the 12th century. Of the former the most important was the *Glossa ordinaria* of Walafrid Strabo, which was esteemed the chief exegetical manual for some six centuries. Throughout the Middle Ages, full as these were of theological activity, dogmatic and polemic, hermeneutics became more and more a tradition. The less the Bible was studied in a free spirit, the more it became the subject of strained panegyric. Aquinas, indeed, though his practice was often in conflict with his theory, could still speak of the literal sense as that on which all the senses of Scripture are founded, and of argument as to be drawn only from that one literal sense and not from those senses which are expressed according to allegory (*Summa*, i. 1, art. 10). But at last independence was so completely resigned that John Gerson, the illustrious chancellor of Paris, was only the exponent of the prevalent opinion, when he declared that those who did not take the literal sense as the church defined it ought to be dealt with not by curious reasonings but by statutory penalties.

3. But alongside these two hermeneutical tendencies there can be traced from the earliest times, however obscurely or fitfully, a third which we term the *Historical*. Men like Irenæus, Origen, Augustine, &c., were not wholly incapacitated for the exercise of a better method by their allegorical or dogmatic bias. There has been a line of interpreters, slender enough as that line has been at times, who have recognized it to be the exegete's object to discover the one sense intended by the writer himself, who have allowed allegory therefore only where the writings themselves indicated their mystical design, and who have laid the first importance on the grammatical sense and on the capacity of transporting oneself into the writer's position. Even Alexandria presents in the great Athanasius and in Isidore notable instances of interpreters who, though given to occasional spiritualizing, proceed on the principle of the *ἀνταρκεία* of Scripture (this specially in the case of Athanasius), and on the necessity of considering the occasion of each writing. But in direct antithesis to the allegorizing school of Alexandria stood the school of Antioch, which was grammatical and historical, with a tendency to an extreme literalism which yielded in not a few cases a jejune and unspiritual exegesis. Theophilus and Julius Africanus may claim a place in this order. But the acknowledged representatives of the Antiochene school are Lucian of Samosata, who is sometimes reckoned its real founder, Diodorus of Tarsus, Theodore of Mopsuestia, and above all John Chrysostom and Theodoret of the Syrian Cyrhus. The last two, while not less careful of the

objective sense, surpassed the others in spiritual insight. Chrysostom abounds in sound hermeneutical statements which strike a happy mean between Alexandrian arbitrariness and the unethical superficiality into which extreme Antiochene interpretation sank. He withstands the imposition of foreign senses as a practice dishonouring to the Word of God, and yet shows how much there is that must be taken otherwise than as it stands. He insists upon the importance of ascertaining the "scope" of a writing in order to a correct judgment of its separate declarations, on the necessity of the revelation of the Spirit, on the respect due to the harmony of Scripture with itself. He lays it down as a general principle that, when allegory is employed, the Bible also gives its interpretation as a check upon the unbridled desire of those who wish to allegorize (*Hon. in Genes. v.*). Theodoret exhibits a kindred sobriety, and, though occasionally guilty of seeking a secondary sense where the obvious sense seems too bald, ranks deservedly among the very best of ancient exegetes. Principles similar to the Antiochene prevailed for a long period also in the schools of Edessa and Nisibis. The objective tendency found representatives, too, in men like Basil of Caesarea, Gregory of Nazianzus, Gregory of Nyssa (although he was less decidedly historical, and strongly advocated a non-literal reading of Canticles in particular), Pelagius, and the laborious Jerome. This last-named ornament of the Latin Church, although he too often drifted into fanciful and even puerile interpretations, was strongly opposed both to the allegorists and the extreme literalists. Against the former he affirmed that the grammatical and historical sense must be held the fundamental thing. Against the latter he insisted that the figurative interpretation is not necessarily equivalent to the allegorical, and that the gospel is to be sought not in the words but in the sense of Scripture, not in the surface but in the marrow, not in the leaves of discourses but in the root of the idea (*Comm. in Habac. iii. 14; in Epist. ad Galat. i. 11*). In the unproductive centuries which followed, this purer hermeneutical tendency appears occasionally in such instances as those of Druthmar, "the grammarian;" Œcumenius, bishop of the Thessalian Tricea, who belongs to the 10th century; Theophylact, bishop of Achrida in Bulgaria, "the last of the fathers"; Rupert of Deutz and Euthymius Zigabenus, who carry us into the 12th century.

A great impetus was given to independent hermeneutics by the Humanists and the precursors of the Reformation. An eminent position is occupied by Nicolans de Lyra, to whose *Postillæ*, or brief commentaries on the whole Bible, Luther and the Reformers owed a debt expressed in the familiar distich, "Si Lyra non lyrasset, Lutherus non saltasset." The current fourfold division of the sense of Scripture still appeared in his writings, but for the most part only as a theoretic division. He allowed occasional spiritualizing, but that mostly in the form of professed practical application of the proper sense. He declared anew the necessity of adhering to the plain objective meaning, likening the mystical interpretation which departs from the solid basis of the literal sense to a building which deviates from its foundation and inclines to its fall. On the side of grammar and philology the reaction was helped by Laurentius Valla and other Humanists, although the services of Reuchlin in particular, great as they were in the assertion of exegetical freedom and in the restoration of linguistic science, were impaired by cabalistic predilections (*cf. specially his De verbo mirifico*). On the religious side, something was achieved by men like Wycliffe, Huss, Wessel, who all perceived the primary importance of the grammatical method, and Faber Stapulensis (Lefèvre d'Étapes), who affirmed the sufficiency of the Word, and practised an independent, non-dogmatic exegesis. It is

matter of course that Erasmus should claim special notice in this connexion. In this consummate scholar and versatile genius, who continued and vastly excelled all that had been attempted by Valla and others, and whose guidance the Reformers were wise enough to follow, notwithstanding the frequent deficiencies of his exegesis in depth and spiritual insight, we come at length upon a master hand that marks a great epoch. Indecision clings indeed to his utterances on some subjects. He speaks with caution on the infallibility of the church and the church's head, although he lets us see that he rejects it. He admits the existence of occasional inaccuracies in the Scriptures. But he declares that these are so far from being disadvantageous to the gospel that they are turned by the Spirit into a help to faith. He adds at the same time that if the authority of the entire Scripture should be supposed to be impaired by the presence of the smallest error in it, it is more than probable that none of the copies now used by the Catholic Church is so perfect as to be free from the intrusion of all mistakes, accidental or intentional (*cf. Annot. in Matt. ii. 6*). But his clear enunciation of the interpreter's independence and the inquirer's obligation to become bound by the authority of no one (*In Luc. ii. 35*), his advocacy of the translation and free circulation of the Scriptures, his repudiation of any other sense than what was meant to be conveyed, his sagacity in dealing with the figurative sections of both Testaments, his recognition of the need of a "pia curiositas" and a "curiosa pietas" in the exposition of the divine word (*cf. Pref. to Paraph. in Evang.*), his practice of the true exegetical art in his *Paraphrases* and *Annotations*, contributed powerfully to the diffusion of better hermeneutical ideas.

The mightiest impetus was given by the Reformers. They were the heirs of what was best in the ancient school of Antioch and in the Humanistic revival. But they added to the philology, the grammar, the history, and the independence which were illustrated in these the spiritual insight and the personal religious interest which were so often wanting. The process by which they won their own way to a freer faith lifted them above tradition, mysticism, and unspiritual literalism. Their profound religious experiences, intensified by the forces at work in an unexampled mental upheaval, made the Bible a new thing to them. It came to them as God's message, and they received it as the only rule of faith and life. It spoke immediately to their souls, and they saw it was to be interpreted by itself. They found it a message conveyed in historical form, and recognized the need of the appliances of language and history in order to read it. They perceived it to be a spiritual message, and discovered that the full reception of it could come only by spiritual enlightenment. Believing it to be a message meant for all, they held it perspicuous to the general intelligence of the prayerful in all that concerns faith and morals, and affirmed, with Melancthon, "unam et certam et simplicem sententiam ubique querendam esse juxta præcepta grammaticæ, dialecticæ, et rhetoricæ." Each of the great Reformers did something to advance this truer hermeneutical movement. Luther, Zwingli, and Calvin were alike imbued with the historic sense, Luther excelling in spiritual genius and a bold originality which carried him at times to extremes in the independence of his treatment of Scripture, Zwingli in an incisive perception which inclined strangely at times to subjective interpretations, Calvin in a union of qualities which distinguished him as the foremost exegete of the Reformation. Profoundly reverencing Scripture as God's word, submitting to it as authoritative, yet not binding himself to any theory of its inspiration which would preclude the possibility of circumstantial inaccuracies (*cf. on Matt. xxvii. 9, Acts vii. 16*), the Reformer of Geneva excelled all in freedom from arbitrary exposition, in reading

the Biblical statements in the light of historical occasion and intention, in laying the foundations of a truer typology, and in exhibiting with its Christward testimony the historical basis of Messianic prophecy. The coryphæi of Protestant exegesis were aided by Beza, Bucer, Bullinger, Œcolampadius, and others. At length the hermeneutics of the Reformation found symbolical expression in the Protestant definitions of the exclusive sufficiency of Scripture, its perspicuity under the use of the ordinary means and with the teaching of the Holy Spirit, its possession of a sense which is one and not manifold, and its interpretation by itself. In the *Clavis Scripturæ Sacræ* of M. Flacius Illyricus it was cast for the first time into systematic form, and dealt with theoretically.

With the Reformation objective exegesis may be said to have been firmly established. The conditions were also laid for further hermeneutical progress. Since then the principles of true grammatico-historical interpretation have been gradually coming to be better understood and more successfully applied. This has not been the case, however, without frequent relapses. In various schools there have been revivals of old errors. There has been a return to the subjective tendency, e.g., in the "moral interpretation" of Kant, as well as in various forms of rationalistic and Socinian exegesis. In accordance with his ideas of the empiric and local order of an historical faith, and his definition of morality as the essence of religion, Kant held that the judgments of the pure reason must be the test of religious truth, and that the literal sense, when it seems to convey a meaning adverse to morality, inconsistent with reason, or unworthy of God, must have a new meaning found for it. His hermeneutics, therefore, did not profess to rest with the sense intended by the writer, but reckoned it legitimate to adopt any possible sense which should be conformable to the interests of perfect morality. To the same tendency belong the "psychological interpretation" of Paulus and Eichhorn, and the mythical interpretation of Weisse and Strauss. Of these the former proposed to hermeneutics the task of distinguishing the realities from the inexact impressions formed of facts by the sacred writers, while the latter sought principles by which the idea might be disentangled from the narrative vesture which it had woven for itself. Pietism, too, although its leaders, Spener and Francke, were of a better spirit, degenerated through its straining after "edifying" interpretation into mystic and chiliastic licence. The dependent tendency, again, formulated in the symbolical definitions on the subject of the Vulgate as the basis of exegesis, the church as the authoritative interpreter, and the pope as the infallible exponent of the church in official declarations on faith and morals, has become so firmly seated in the Roman Catholic communion that the interpreter's attitude to the church is capable of being compared by a Catholic author to that of a diplomatist acting in the spirit and interest of his prince.¹ It is followed, too, by that section of the English Church which defers to primitive tradition or the consent of the fathers of the first four centuries. Even among those who adhere to the Protestant positions there has been partial reaction in both directions. The subjective tendency has reasserted itself, e.g., in the artificial typology of the Cocceian school, although Cocceius himself rather deserves the credit of making Protestant theology, after it had entered its scholastic period, again more Biblical, and of enforcing the importance of a literal, contextual interpretation. The dependent tendency has reappeared where the "analogy of faith," instead of being kept to the original idea of the general contents of Scripture as gathered from the lucid passages and used for a help to the understanding of the

obscurer, has been identified with the creeds and employed as an external standard of interpretation.

But with partial retrogression there has been an advance on the whole in Protestant hermeneutics. To this interpreters of very different schools have contributed. Among these are to be mentioned Sal. Glassius, the author of the *Philologia Sacra*, Hugo Grotius, Abr. Calov, G. Calixtus, J. J. Rambach, whose *Institutiones Hermeneuticæ Sacræ* exercised a salutary influence, notwithstanding his inclination to the pietist principle of "emphasis" in interpretation; J. A. Bengel, in whose *Gnomon* a happy union was effected between pietism and science; and J. S. Semler, who did much for the expansion of historical interpretation, notwithstanding the injurious results of his theory of accommodation. Of still greater importance are J. A. Ernesti, to whose celebrated *Institutio Interpretis Novi Testamenti* last century was indebted for the scientific presentation of the soundest hermeneutical principles on the philological side; Friedr. Schleiermacher, whose *Hermeneutik* abounded in fertile suggestions, and brings out for the first time the necessity of recognizing a specifically Christian element in the language of the New Testament; and F. Lücke, who illustrates the just combination of the strictest scientific method with the primary qualification of spiritual sympathy with the Word in the true interpreter. Extensions of hermeneutical method have been attempted, in the form of defining a special "psychological" (Ständlin), "theological" (Klausen, Landerer), or "dogmatic" (Doedes) interpretation, or in the form of proposing new modes of interpretation, such as the "æsthetical" of Pareau, the "pneumatical" of Beck, the "panharmonic" of Germar. But whatever is valid in these schemes comes within the ordinary grammatico-historical method. Properly understood, the historical side of that method covers all that concerns the transportation of the exegete, not only into the times and circumstances of the composition of the books, but also into the position and personality of the authors. It embraces therefore that subjective quality which, however variously designated as the religious preparation, sympathy with the writers and their message, spiritual tact, or the illumination of the Holy Spirit, has been recognized by the best interpreters to be a primary and essential requisite. The development of these principles has been greatly helped by the grammatical studies of men like Gesenius, Ewald, Cisthausen, and Böttcher in Hebrew, and Winer and Buttmann in Greek; by the literary, historical, critical, and theological investigations of Herder, Baur, Rothe, Hofmann, and many others; and above all by the exegetical practice of scientific expositors such as De Wette, Bleek, Hupfeld, Lücke, Meyer, Godet, Ellicott, Lightfoot, and Delitzsch. Results are thus being gathered which will issue in new enlargements of hermeneutical method. A clearer insight is being gained into the genius of the languages, which has already rescued New Testament Greek from purist and Hebraist extremes, and into the nature of typology, the laws of prophecy, the relation of the two Testaments to each other, the historical delivery and development of their contents, the unity (so distinguishable from uniformity) which animates their different sections. In these directions there is the promise of further progress in hermeneutics. More exact inquiry into the presuppositions which underlie the Biblical doctrines will also tell upon the laws of interpretation. Differences in hermeneutical method, however, run up finally into differences of conception on the origin of the sacred literature, its intention, and the spirit which animates it. Uncertainty of view on the subject of what Scripture is and what its inspiration covers, as seen in the symbols of the churches and in the widely divergent positions affirmed by representative theologians of different schools (cf., e.g., those expounded respectively by Chemnitz

¹ Loehnis, *Grundzüge der biblischen Hermeneutik und Kritik*, p. 151. Giessen, 1839.

Beck, Schleiermacher, Martensen, Hodge, Ewald, Rothe, Hofmann), exercises a disturbing influence. More determinate conclusions on the definition of Scripture, such as can be the result only of completer historical investigation into the rise and object of the several books, must yet be reached before a thorough adjustment is possible between the religious interest and the scientific in Biblical hermeneutics.

Literature.—On the history generally:—Buddæus, *Isagoge hist. theol.*, &c., 1730; Hartmann, *Die enge Verbindung des A. T. mit dem N. T.*, 1831; J. G. Rosenmüller, *Historia interp. libr. sacr. in eccl. Christ.*, 5 vols., 1795–1814; G. W. Meyer, *Geschichte der Schriftklärung seit der Wiederherstellung der Wissenschaften*, 5 vols., 1802–8; L. Diestel, *Geschichte des alten Testaments in der christ. Kirche*, 1869; also the notices in Reuss's *Geschichte der heil. Schriften N. Test.*; the Introductions to the Old Testament by Keil and Bleek, and De Wette's *Lehrbuch der historisch-kritischen Einleitung in das Alte und Neue Testament* (edited by Schrader), 1869; and the sketches in Klausen's *Hermeneutik des N. T.* (German edition, Leipsic), 1841; J. L. Lutz's *Biblische Hermeneutik*, 1861; S. Davidson's *Sacred Hermeneutics*, 1843. On the Rabbinical Hermeneutics:—Surenhusius, *Βίβλος καταλλαγῆς*, 1713; Zunz, *Die gottesdienstl. Vorträge d. Juden*, 1832; Pressel's article "Rabbinismus," in Herzog's *Real-Encyclopädie*; Hirschfeld, *Der Geist der talmudischen Auslegung der Bibel* (Erster Theil, "Halachische Exegese," 1840), and *Der Geist der ersten Schriftauslegungen, oder die hagalische Exegese*, 1847; Frankel, *Vorstudien zu der Septuaginta*, 1841; E. Deutsch, *Literary Remains*, 1874; and the sections in Jost's *Geschichte des Judenthums und seiner Secten*, Grätz's *Geschichte der Juden*, Derenbourg's *Histoire de la Palestine*, Hausrath's *Neutestamentliche Zeitgeschichte*, Schürer's *Lehrbuch der Neutestamentlichen Zeitgeschichte*, and Gröber's *Jahrhundert des Heils*. On the Kabbala also:—Delitzsch, *Zur Geschichte der Jüdischen Poesie*, 1836; Jellinek, *Moses ben Schem Tob de Leon und sein Verhältniss zum Zohar*, 1851; Ginsburg, *The Kabbalah, its Doctrine, Development, and Literature*, 1865. On the Alexandrian School:—Gröber, *Philo und die alexandrinische Theosophie*, 1831; Keim, *Geschichte Jesu von Nazara*, vol. i.; Siegfried, *Philo von Alexandria als Ausleger des A. T.*, 1875; Frankel, *Ueber den Einfluss der palästinschen Exegese auf die alexandrinische Hermeneutik*, 1851 and *Ueber palästinsche und alexandrinische Schriftforschung*, 1854; the monographs by Kaye on Clement and Thomasius, and Redepenning on Origen; C. R. Hagenbach, *Obs. circa Origenis methodum interp.*, 1823; J. J. Boehlinger, *De Origenis allegorica S.S. interpretatione*, 1829. On the Antiochian School:—Hergenröther, *Die Antioch. Schule und ihre Bedeutung auf exeg. Gebiete*, 1866; Kühn, *Die Bedeutung der Antioch. Schule auf dem exeg. Gebiete*, 1867; Specht, *Der exeg. Standpunkt des Theodor von Mopsuestia und Theodoret von Kyros in der Auslegung mess. Weissag.*, 1871; also the monographs on Chrysostom by Neander, Meyer, Förster, and Stephens. Of the treatises referred to above, the following are of special importance:—M. Flacius, *Clavis S. Scripture* (by Musæus), 1674; Rambach, *Institutiones Hermeneuticæ*, 1723; Ernesti, *Institutio interp. N. T.* (in English by Terrot, 1843); Schleiermacher, *Hermeneutik und Kritik mit besond. Beziehung auf das N. T.* (by Lüke), 1838; Fr. Lüke, *Grundriss der Neutest. Hermeneutik*, 1817. In addition these also deserve notice:—S. F. N. Morus, *Super Hermeneutica N. T. acroasis academ.*, 1797–1802; Olshausen, *Ein Wort über tiefere Schriftsin.*, 1824; Kuene, *Critices et Hermeneutics librorum Novi Fæderis lineamenta*, 1858; Dopke, *Hermeneutik der Neutest. Schriftsteller*, 1829; Wilke, *Die Hermeneutik des N. T. systematisch dargestellt*, 1843–44; Immer, *Hermeneutik des N. T.*, 1873, English edition by Newman, Andover, 1877; Cellerier, *Manuel d'Hermeneutique biblique*, 1852; Doedes, *Manual of Hermeneutics*, 1867; Lango, *Grundriss der bibl. Hermeneutik*, 1878. On the Hermeneutics of the Roman Catholic Church, in addition to Loehuis, there may be mentioned—J. Jahn, *Enchiridion Hermeneuticæ generalis tabularum Vol. et N. T.*, 1812; Ranolder, *Herm. bibl. gen. principia rationalia*, 1839; Kohlgruber, *Herm. bibl. gener.*, 1850; Güntner, *Herm. bibl. gener.*, 1851; Setwin, *Herm. bibl. institutiones*, 1872; Reithmayr, *Lehrbuch der bibl. Herm.*, 1874; Friedlieb, *Prolegomena zur bibl. Hermen.*, 1868; Wilke, *Bibl. Hermen.*, 1853. Important discussions of sections of the subject are found in Seyffarth, *Ueber Begriff, Anordnung, und Umfang der Herm. des N. T.*, 1824; J. C. K. von Hofmann, *Vermischte Aufsätze*, 1878; John Keble, *Primitive Tradition recognized in Holy Scripture*, 1837, and *On the Mysticism attributed to the Early Fathers of the Church*, 1868; Merx, *Eine Rede vom Auslegen insbesondere des Alten Test.*, 1879. (S. D. F. S.)

HERMES is the name of a Greek god (corresponding to the Roman Mercury) whose origin and real character are perhaps more difficult to define than is the case with any other Greek deity; here it is possible only to give an out-

line of one definite theory, and refer the reader to the works quoted at the end. He was not a god worshipped by the pure Doric or Ionic races, but is found in most places where Æolian, Achæan, and Pelasgic tribes can be traced. If we begin with the rudest races, summed up generally under the title of Pelasgic, we find Hermes often connected with the mysterious Cabiri. These deities, in the accounts we have, vary in number and sex, being sometimes two, sometimes three or four. We may conclude that originally they were a pair, male and female, whom we may compare with Uranus and Gæa, or with Cronus and Rhea. Often the female is doubled, as mother and daughter, resembling the relation of Demeter and Persophone; while the male also is transformed either into twin brothers, or into a father and his son by one of the female deities. Certainly the male deity seems sometimes to be regarded as Hermes, sometimes as Hephæstus (see ΗΕΡΚΕΣΤΟΣ), while in other places the two are associated. Hermes and Hephæstus are perhaps local varieties of one type, which after having acquired distinct individuality in their separate homes were brought beside each other by subsequent intercourse. Hence we may understand how the epithet ἄγγελος and the office of messenger between gods and men, which in the *Rig Veda* belong to Agni, the fire, are in Greek mythology attached to Hermes. This Pelasgic Hermes is an ithyphallic deity, the god of fertility and reproductive power, and bestower of riches in flocks and herds. Corresponding to this religious conception we have in mythology such epithets as ἐριόινος, ἀκάκητα, &c.; and in the hymn to Aphrodite (written perhaps in Æolis in the 9th century B.C.); Hermes and the Sileni (Latin *Silvani*) are the companions of the mountain nymphs. So in Arcadia, one of the chief seats of his worship, where on Cyllene his birthplace was shown, he was by Penelope the father of Pan. Penelope, the "torch-eyed" (Ahrens in *Philol.*, 1879, p. 205), is a form of Athene, Odysseus of Hermes; and Hermes and Athenē are associated as Hephæstus with Athene in Attica. In the very mixed Attic people, it is not surprising to find the worship of Hermes widespread; it is sometimes said to have been introduced from Samothrace. In Athens Hermes is the god of social life and intercourse in general, of streets and doorways, and of the palestra. He is worshipped as ἀγοραῖος and προπύλαιος; and Hermes, pillars supporting a bearded head and furnished with a phallus, stood all over the city. In Ætæia also we find Hermes, especially at Tanagra, where Hermes the champion, and Hermes κροφόρος, the averter of diseases, were worshipped. The Doric god Apollo, with the titles Agyieus and Paion, corresponds most closely to these last aspects of Hermes. As god of social intercourse he easily grows into the impersonation of cleverness, and at last into the patron of thieves. If we pass from religion to mythology, where we find all the successive ways of expressing views of nature preserved to us side by side, we find an immense variety of traditions. The most common subject in these tales is the struggle between darkness and light. When it is said that Hermes stole the oxen of Apollo, and after killing two of them nailed their skins on a rock, we have one of a class of myths described at length by Kuhn (*Entwicklungsstufen der Mythologie*). The slain animal is the sun, who is killed every evening; and the hide, i.e. the sky of night, is either hung up on the tree of heaven (as is the Golden Fleece) or fastened with the star-headed nails. Again, when Io, the moon, is watched by the hundred-eyed Argus (Sanskrit *rajas*, "darkness"), the star-studded sky, Hermes slays Argus with a stone, the same which Cadmus and Jason use, viz. the rising sun. In both cases Hermes is the sun-god as hidden during the night away among the souls of the dead: hence the Chthonian character

so frequently attached to him. The rod with which he lulls men to sleep is the same sceptre that the ruler of the dead, Yama or Rhadamanthus, Minos or Hades, always bears (Kuhn in *Zft.*, iv. p. 123); he is also the sender of dreams; we find him worshipped among the Chthonian deities at Cnidus, and on vases accompanied by the Chthonian dog. We are now able to understand a fact which is perhaps the most interesting point connected with Hermes. Kuhn first pointed out the identity of the Greek *Ἑρμῆας* with the Sanskrit *Sārameyas*, and though the connexion has been doubted by various writers, as Mannhardt (*Wald- und Feld-Kulte*, ii. pref.) and others, yet no valid objection has ever been offered on etymological grounds (see Benfey in *Abhandl. Gött. Ges.*, 1877). Amid the difficulties which still envelop the translation and the mythology of the Vedas, it is, however, even more difficult to discover the original character of the two *Sārameyas* and their mother *Saramā*, than it is to determine the nature of Hermes. The two *Sārameyas* are mentioned twice in the *Rig Veda* (vii. 55; x. 14); they are two dogs, are said both to guard the way to the abode of the dead and refuse a passage to the impious, and also to act as the messengers of Yama, carrying away the souls when the time of death has arrived. *Saramā* also seems to be regarded as the messenger or the dog of Indra; and Hermes appears regularly as the companion and helper of all the light-heroes on their adventures. One epithet of these dogs is *Ḍarvara*, spotted, which in its Greek form Cerberus (Benfey, *Vedica*, p. 149) is the name of the dog that guards the gate of the lower world. Now we find in Rome that two *laræ præstitæ*, children of Mercury and Egeria, are said to guard dwellings and streets in the form of dogs; and in the German legend the dog who attends the wild huntsman Wuotan, *i.e.*, the sun hidden during the seven winter months, is closely related to the dwarfs or spirits of the dead, and is called by their name (Kuhn, *Westf. Sagen*, i. p. 69c). So Hermes, whom we have seen as king of the dead, is as *ψυχοπομπός* also the conductor of souls to their future home; we may therefore count the dog (or dogs) as ultimately identical in character with the king of the dead. Sonne (on Charis in Kuhn's *Zft.*, x.) has pointed out how these primitive conceptions commonly pass through the stage of animals before reaching that of gods; and in mythology we have the two stages preserved side by side as distinct beings. The Hindu Kubera, lord of the treasures of the lower world, who may be identified with Pluto or with Hermes, is styled "Lord of the hosts of the *Sārameyas*."

In this account there has been no room left for the idea of Hermes as connected with the wind. The sun, after he has set at night, is the same as the sun hidden during the dreary months of winter, who then rides abroad in the tempest. The wind is then easily conceived as his servant and messenger, and is often considered to carry away the souls of the dead (see HARPYES). From his connexion with the wind, Hermes is represented with winged shoes. But with Roscher (*Hermes der Wind-Gott*) to see in Hermes simply the wind is to take a narrow view and to ignore the character of primitive Aryan thought.

In art, besides the *Hermæ* already described, Hermes is in the archaic time represented as a man with pointed beard, wearing a chlamys and the broad hat called *petasus*; his symbols are the staff (*κηρύκειον*) and the winged shoes (*talaria*). The ideal type of Hermes was probably modelled after the statue by Praxiteles in the Heraion at Olympia. This statue, which was recently discovered by the German expedition, represented the god leaning with his left arm on a rock and supporting on it the infant Bacchus. The right arm, which is lost, probably held the caduceus. The form shows a perfect combination of agility and strength.

See the works on mythology or religion by Weleker, Gerhard, Rinck, Stühr, Schweneck, O. Müller, Eckermann, H. D. Müller, Lauer, Schwartz, Max Müller, Preller, Hartung, Braun, Maury, &c.; also Lehms, *Popularische Aufsätze*; Schömann, *Hesiod. Theog.*; Götting in *Hermes*, xxix.; Mehlis, *Grundriss des Hermes, Myriantheus Aqoins*; Haupt in *Zft. f. Alterth.*, 1842; Oestermann, *Hermes-Odyssæus*; H. D. Müller in *Philologus*, xiv.; Kuhn in Haupt's *Zft. f. d. Alterth.*, vi.; Von Hahn, *Sagwissenschaft. Studien*; Roscher, *Hermes*. As usual, the fullest list of ancient authorities is to be found in Jacobi, *Handwörterbuch der Mythologie*. (W. M. RA.)

HERMES, GEORG (1775-1831), a distinguished Catholic theologian, born on 22d April 1775, at Dreyerwald, in Westphalia, was educated at the gymnasium and university of Münster. His life presents no facts of importance. After completing his course of study at Münster, he acted for some time as lecturer at the gymnasium and then as professor at the university. In 1820 he was called, as professor of theology, to the university of Bonn, where he remained till his death on 26th May 1831. Hermes was peculiarly adapted for the life and work of the professoriate. He had great gifts as a lecturer and teacher, and gathered round him at Bonn a devoted band of adherents. His works were *Untersuchungen über die innere Wahrheit des Christenthums*, Münster, 1805, and *Einleitung in die Christkatholische Theologie*, of which the first part, a philosophical introduction, was published in 1819, the second part, on positive theology, in 1829. The *Einleitung* was never completed. His *Christkatholische Dogmatik* was published, from his lectures, after his death by two of his scholars, Achterfeld and Braun, 3 vols. 1831-4.

The *Einleitung* is a remarkable work, both in itself and in its effect upon Catholic theology in Germany. Few works of modern times have excited a more keen and bitter controversy. Hermes himself was very largely under the influence of the Kantian and Fichtean ideas, and though in the philosophical portion of his *Einleitung* he criticizes both these thinkers severely, rejects their doctrine of the moral law as the sole guarantee for the existence of God, and condemns their restricted view of the possibility and nature of revelation, enough remained of purely speculative material to render his system obnoxious to the Catholic Church. A very few years after his death, the contests between his followers and their opponents grew so embittered that reference of the dispute was made to the papal see. The judgment consequent upon a review of Hermes's writings, undertaken in Rome in 1833, was adverse, and on 25th September 1835 a papal bull condemned both parts of the *Einleitung* and the first volume of the *Dogmatik*. Two months later the remaining volumes of the *Dogmatik* were likewise condemned. The controversy did not cease with this condemnation; but not till 1845 was there any systematic attempt on the part of Catholic theology to examine and refute the *Hermesian* doctrines. In that year was published anonymously by F. X. Werner the most complete survey of the principles of the works of Hermes as contrasted with the orthodox catholic faith (*Der Hermesianismus*, 1845). In 1847 the condemnation of 1835 was confirmed by Pius IX. A sufficient account of Hermes and the dispute raised by him will be found in K. Werner, *Geschichte der Katholischen Theologie*, 1866. vol. 405 sqq.

HERMES TRISMEGISTUS. The Egyptian Thoth, Taut, or Tat (see vol. vii. p. 718), who was identified by the Greeks more or less completely with their own Hermes, is described in the hieroglyphics by various epithets, among which occurs that of "the great great" or twice great, with an added hieroglyphic (a kite) also signifying "great." To him as scribe of the gods, "Lord of the divine words," "Scribe of truth," was attributed the authorship of all the strictly sacred books generally called by Greek authors *Hermetic*. These, according to Clemens Alexandrinus, our sole ancient authority (*Strom.*, vi. p. 268 sq.), were forty-

two in number, and were subdivided into six divisions, of which the first, containing the ten books "of the prophets," dealt with laws, deities, and the education of priests; the second, consisting of the ten books of the "stolistes," or official whose duty it was to dress and ornament the statues of the gods, treated of sacrifices and offerings, prayers, hymns, festive processions; the third, "of the hierogrammatist," also in ten books, was a repertory of hieroglyphical, cosmographical, geographical, and topographical information; the four books "of the horoscopus" were devoted to astronomy and astrology; the two books "of the chanter" contained respectively a collection of songs in honour of the gods and a description of the royal life and its duties; while the sixth and last division, consisting of the six books "of the pastophor," was medical. Of this canon, which according to the generally received opinion of Bunsen must have been closed at latest in the time of the Psammetichi but probably earlier, numerous small fragments are to be found in the works of Stobæus and other ancient writers. The now well-known *Book of the Dead*, according to Bunsen, originally had its place among the ten ceremonial books of the "stolistes," but this is denied by Lepsius; an ancient papyrus recently deciphered by Ebers is believed by that author to date from about the year 1500 B.C., and to have formed part of one of the books of the pastophor.

The epithet Trismegistus (ὁ τρισμέγιστος, or "superlatively" greatest), as applied to Hermes, is of comparatively late origin, and cannot be traced to any author earlier than the 2d Christian century. Most probably it arose out of the earlier forms μέγας καὶ μέγας or μέγιστος, derived by the Greeks from early Egyptian sources; but various other explanations of the appellation have been offered, such as that of the author of the *Chronicon Alexandrinum* (47 A.D.), who maintains that it was because Hermes, while maintaining the unity of God, had also asserted the existence of three supreme or greatest powers that he was called by the Egyptians Trismegistus.¹ This view, which is also adopted by Suidas, seems preferable at least to that met with in Nicolai's *History of Greek Literature*, according to which an apocryphal author named Hermes was called τρισμέγιστος, simply in order to indicate that he had succeeded and outdone a certain Megistias of Smyrna in astrological, physiognomical, and alchemistic theories. The name of Hermes seems during the third and following centuries to have been regarded as a convenient pseudonym to place at the head of the numerous syncretistic writings in which it was sought to combine Neo-Platonic philosophy, Philonic Judaism, and cabalistic theosophy, and so provide the world with some acceptable substitute for the Christianity which had even at that time begun to give indications of the ascendancy it was destined afterwards to attain. Of these pseudepigraphic Hermetic writings some have come down to us in the original Greek; others survive in Latin or Arabic translations; but the majority appear to have perished. That which is best known and has been most frequently edited is the ποιμάνδρης sive *De Potestate et Sapientia Divina* (ποιμάνδρης being the Divine Intelligence ποιμήν ἀνδρῶν), which consists of fifteen chapters treating of such subjects as the nature of God, the origin of the world, the creation and fall of man, and the divine illumination which is the sole means of his deliverance. The *Ediitio Princeps* appeared in Paris in 1554; and there has been a recent edition by Parthey (1854); the work has also been translated into German by Tiedemann (1781). Along with it are usually printed the certainly later ὄροι or *Definitions* of Asclepius, which have sometimes but erroneously been attributed to Apulcius. Other Hermetic writings which

have been preserved, and which have been for the most part collected by Patricius in the *Nova de Universis Philosophia* (1593), are (in Greek) Ἱατρομαθηματικὰ πρὸς Ἄμμωνα Αἰγύπτιον, Περὶ κατακλίσεως νοσοῦντων περιγνώστικά, Ἐκ τῆς μαθηματικῆς ἐπιστήμης πρὸς Ἄμμωνα; (in Latin) *Aphorismi sive Centiloquium, Cyranides*; (in Arabic, but doubtless from a Greek original) an address to the human soul, which has been translated by Fleischer (*An die menschliche Seele*, 1870). The connexion of the name of Hermes with alchemy will explain what is meant by hermetic sealing, and will account for the use of the phrase "hermetic medicine" by Paracelsus, as also for the so-called "hermetic freemasonry" of the Middle Ages.

See Ursinus, *De Zoroastre, Hermete, &c.*, Nuremberg, 1661; Lenglet Dufresnoy, *L'Histoire de la Philosophie Hermétique*, Paris, 1742; Baumgarten-Crusius, *De librorum hermeticorum origine atque indole*, Jena, 1827; Hilger, *De Hermets Trismegisti Poemandro*, 1855; Ménard, *Hermès Trismégiste: Traduction complète, préface d'une étude sur l'origine des livres hermétiques*, 1866; Pietschmann, *Hermès Trismegistus, nach Ägyptischen, Griechischen, und Orientalischen Uebersetzungen*, 1875.

HERMESIANAX, an elegiac poet of the Alexandrian school, was born at Colophon, and flourished in the time of Philip and Alexander, or a little later. He was a friend and admirer—probably also a pupil—of the grammarian and poet Philetas, whom he outlived. His chief work was a poem in three books, which he, following the example of his countrymen Mimnermus and Antimachus, inscribed with the name of his mistress Leontium (said by some to be the same as the mistress of Epicurus). Of this poem a fragment of about one hundred lines has been preserved by Athenæus (xiii. 597); and it may serve as a specimen of the style of the school. Erotic in character, and plaintive in tone, it enumerates instances, mythological and historical, of the irresistible power of love, and redeems the monotony of its ground plan by its picturesque language, and by the alternate force and tenderness of its treatment. Hermesianax was exceedingly popular in his own times, and was highly esteemed even in the Augustan period. Propertius follows his example in dedicating the first book of his *Elegies* to his mistress Cynthia.

Many scholars have laboured upon the text, but it is still in a very unsatisfactory condition. See Hermann, *Opuscula*, iv.; Schneidewin, *Delect. Poes. Eleg.*; Bergk, *De Hermesianactis Elegia*; the editions of Bailey (London, 1839), &c.

HERMOGENES, of Tarsus, Greek rhetorician, flourished in the reign of Marcus Aurelius. His precocious ability secured him a public appointment as teacher of his art while as yet he was only a boy; but at the age of twenty-five his faculties gave way, and he spent the long remainder of his life in a state of intellectual impotency. In the nine or ten years, however, of his activity he composed a whole series of treatises on matters rhetorical, which became popular text-books, and the subject of subsequent commentaries. Of his Τέχνη ῥητορικὴ we still possess Περὶ τῶν στάσεων; Περὶ εἰρήσεων; Περὶ ἰδεῶν; Περὶ μεθόδου δεινότητος; and Προγυμνάσματα.

The last-mentioned was only known from Priscian's Latin translation till the publication by Heeren of the Greek original discovered at Turin (*Bibl. für alte Lit. und Kunst*, Gott., 1791). Richard Volkmann, in *Animadversiones criticae in nonnullis veterum de præexercitationibus rhetoricis locis* (Jauer, 1869), discusses the relation of the original to Priscian's translation, and treats them as sources of reciprocal emendation.

HERMON, the highest mountain in Syria (9150 feet above the Mediterranean), an outlier of the Antilebanon. The name ܫܢܝܢ, "separate," is perhaps due to its isolated position. The Sidonians called it Sirion, and the Amorites Shenir (Deut. iii. 9). It is probably the "high mountain" near Casarea Philippi where the Transfiguration occurred (Mark ix. 2). The modern name is *Jebel esh Sheikh*, or "chief mountain." It is also called *Jebel et Thelj*, "snowy mountain." The ridge of Hermon, rising into a dome-

¹ Ἐρμῆς ἔφρασε τρεῖς μέγιστας δυνάμεις εἶναι τὸ τοῦ ἀρρήτου καὶ δημιουργοῦ θεοῦ ὄνομα μίαν θεότητα εἶπεν εἶναι . . . διὰ καὶ ἐκλήθη ἀπὸ τῶν Αἰγυπτίων Τρισμέγιστος Ἐρμῆς.

shaped summit, is 20 miles long, extending north-east and south-west. The formation is a hard dark-grey crystalline limestone belonging to the Neocomian period, and full of fossils. The spurs consist in some cases of white chalk covering the limestone, and on the south there are several basaltic outbreaks. The mountain in spring is covered with snow, but in autumn there is occasionally none left, even in the ravines. To the height of 500 feet it is clothed with oaks and brush, while luxuriant vineyards abound. Above the snow limit the mountain is bare and covered with fine limestone shingle. The summit is a plateau from which three rocky knolls rise up, that on the west being the lowest, that on the south-east the highest. On the south slope of the latter are remains of the small temple or sacellum described by St Jerome. A semicircular dwarf wall of good masonry runs round this peak, and a trench excavated in the rock may perhaps indicate the site of an altar. On the plateau is a cave about 25 feet square, with the entrance on the east. A rock column supports the roof, and a building once stood above. The view from Hermon is very extensive, embracing all Lebanon and the plains east of Damascus, with Palestine as far as Carmel and Tabor. On a clear day Jaffa may also be seen. Other small temples are found on the sides of Hermon, of which twelve in all have been explored. They face the east, and are dated by architects about 200 A.D. The most remarkable are those of *Deir el 'Ashaiyir*, *Hibbariyeh*, *Hosn Niha*, and *Tell Thatha*. At the ruined town called Rukhleh on the northern slopes are remains of a temple, the stones of which have been built into a church. A large medallion 5 feet in diameter, with a head supposed to represent the sun-god, is built into the wall. Several Greek inscriptions occur among these ruins. Foxes, wolves, and the Syrian bear are commonly found on Hermon, with various kinds of game. In the 12th century Psalm lxxxix. 12 was supposed to indicate the proximity of Hermon to Tabor. The conical hill immediately south of Tabor was thus named Little Hermon, and is still so called by some of the inhabitants of the district.

HERMOSILLO, a town of Mexico, state of Sonora, is situated at the entrance to a valley of remarkable fertility near the river Sonora at its confluence with the Horcasitas, 40 miles south-west of Ures. Some of the principal houses are built of stone, but most of the dwellings are of adobe. The town possesses two churches, a prison, and a mint. Its rise and early prosperity were due to the discovery of gold mines in Sonora, but it now depends wholly on the fertility of the surrounding country, of which the principal products are cotton, wheat, grapes, and a great variety of fruits. The town is the commercial centre of Sonora. It has cotton manufactories, flour mills, and brandy distilleries, and carries on a considerable foreign trade by means of the port of Guaymas, which is 100 miles distant. The population is about 14,000.

HERMSDORF, generally known as Niederhermsdorf, a town of Prussia, in the government district of Breslau and circle of Waldenburg. There are coal and iron mines and lime quarries in the vicinity, and in the town there is a large iron-work. The population in 1875 was 5984.

HERMUPOLIS. See SYRA.

HERNIA (a Latin term commonly derived from *ἔρως*, a sprout, but this origin is doubtful) is the protrusion of any viscus from its normal cavity; for example, hernia cerebri is the name given to a protrusion of the brain substance, hernia pulmonum a protrusion of a portion of the lung. The word may here be restricted to its most usual meaning, a protrusion of part of the contents of the abdomen from their normal position in the abdominal cavity,—in common language a "rupture." A rupture may occur at any weak point in the abdominal wall. The common situations are the groin (inguinal hernia), the upper part of the thigh

(femoral hernia), and the umbilicus or navel (umbilical hernia). The contents of a rupture may be any of the abdominal viscera; the more movable the viscus the more tendency there is to protrusion, and therefore we generally find that the small intestine and the omentum are most frequently displaced. The tumour may contain intestine alone (enterocele), omentum alone (epiplocele), or a combination of intestine and omentum (entero-epiplocele). The predisposing cause to rupture is any weakness of the abdominal wall due (1) to natural conformity, as in inguinal hernia, which descends along the inguinal canal, a canal in which the cord lies in the male and the round ligament in the female; or in femoral hernia, in which the hernia descends along the femoral canal along with and to the inner side of the femoral vessels; (2) to any cause which weakens the wall locally, as an abscess or wound; (3) to general laxity of the tissues, as in weakly people, or after repeated pregnancies. This third cause only predisposes to hernia in so far as it may weaken an already weak part under the first and second heads. The exciting cause of hernia is generally some strain or over-exertion in any powerful effort, as lifting a heavy weight, jumping off a high wall, straining, as in difficult micturition or in consequence of constipation, or excessive coughing, as in chronic bronchitis. The pressure of the diaphragm above and the anterior abdominal wall in front acting on the abdominal viscera tends to cause their protrusion at the weakest point. Rupture is either congenital or acquired. A child may be born with a hernia in the inguinal or umbilical region, the result of an arrest of development in these parts; or the rupture may be acquired, first appearing perhaps in adult life, the result of one or other of the accidents referred to above. Ruptures are most frequent at the extremes of life. Men suffer more frequently than women, because they are more liable to those accidents, being frequently exposed to intermittent work, such as the lifting of heavy weights.

At first the rupture is small, and with more or less rapidity it gradually increases in size; it varies from the size of a small marble to that of a child's head or even larger. The swelling which appears is spoken of as consisting of three parts,—the coverings, sac, and contents. (1) The "coverings" are composed of the different structures which form the abdominal wall at the part where the rupture occurs. In femoral hernia the coverings are formed of the structures at the upper part of the thigh. These structures are stretched and may be thinned; in some cases they are condensed and matted together, the result of pressure; in others there is an increase in their thickness, the result of repeated attacks of inflammation. (2) The "sac" is composed of the peritoneum or membrane lining the abdominal cavity; in some very rare cases the sac is wanting. The neck of the sac is the term used to designate the narrowed portion where the peritoneum forming the sac becomes continuous with the general peritoneal cavity. Very frequently the neck of the sac is thickened, indurated, and adherent to surrounding parts, because here the tendency to local inflammatory action is most marked, the pressure being greatest at this point. (3) The "contents" have already been described. There are three distinct conditions in which we may find the contents of a hernial tumour: it may be either reducible, irreducible, or strangulated. A "reducible" hernia is one in which the contents can be pushed back into the abdomen. In some cases this is done with ease, in others it is a matter of great difficulty. At any moment a reducible hernia may become "irreducible," that is to say, its contents cannot be pushed back into the abdominal cavity. This may suddenly occur in consequence of an attack of constipation, or slowly, the irreducibility being at first partial and gradually becoming more

and more complete. Generally this is due to an increase in the size of the omentum, accompanied by inflammatory induration. A "strangulated" hernia is one in which the circulation of the blood through the hernial contents is interfered with. The interference is at first slight, but very rapidly tends to become more pronounced. At first there is congestion; this congestion may go on to inflammation; if unrelieved, the inflammation will end in mortification. The rapidity with which the change from simple congestion to mortification takes place will depend on the tightness of the constricting cause; as a rule the more rapidly a hernia forms, in other words, the less time the surrounding tissues have to accommodate themselves to the protruding swelling, the greater the rapidity of the changes in the conditions of the contents. The constricting agent may be one or other of the structures which form the boundaries of the openings through which the hernia has travelled in its gradual course through the abdominal wall, or it may lie in the neck of the sac, which has become thickened in consequence of inflammation.

Reducible Hernia.—The symptoms of reducible hernia show themselves in a soft compressible tumour (elastic when it contains intestine, doughy when it contains omentum, a combination of elasticity and doughiness when both are present), its size increasing in the erect, and diminishing in the horizontal posture, whence as a rule it gives little trouble during the night, and becomes more troublesome in the daytime, more especially towards evening. There is a more or less distinct impulse on coughing, and when the intestinal contents are pushed back into the abdomen a gurgling sensation is perceptible by the fingers. Such a tumour may be met with in any part of the abdominal wall, but the chief situations are—(a) the inguinal region, in which the neck of the tumour lies immediately above Poupart's ligament (a cord-like ligamentous structure which can be felt stretching from the anterior superior spinous process of the ilium to the spine of the pubis immediately above the genital organs); (b) the femoral region in the upper part of the thigh, in which the neck of the sac lies immediately below the inner end of Poupart's ligament; (c) the umbilical region, in which the tumour appears at the navel. As the inguinal hernia increases in size it tends to pass into the acetabulum in the male, into the labium in the female; while the femoral hernia, appearing first below Poupart, tends gradually as it increases in size to pass upwards superficial to Poupart's ligament.

The treatment of reducible hernia consists in pushing back the contents of the tumour into the abdomen, and applying a truss or elastic bandage in order to prevent the contents from again escaping. The younger the patient the more chance there is of the truss acting as an enervating agent, as the natural tendency to contraction of the channel through which the hernia protrudes is greater. The truss is frequently laid aside at night, because in the horizontal posture the tendency of the contents to descend is greatly lessened. The truss or bandage should, however, be worn day and night. If, after the hernia is once returned, it is never again allowed to come down, there is a probability of a cure taking place; but if it is allowed to come down occasionally, as it may do, even during the night, in consequence of a cough or from turning suddenly in bed, the parts are stretched, and the contracting process which may have been going on for weeks is undone.

It is unnecessary to describe the multitudinous varieties of trusses. When a truss is ordered the surgeon has to see that it fits accurately, the necessary amount of pressure being obtained by means of a steel spring, to which a pad is attached. The pad should be so arranged as to press, not into the opening through which the hernia has come, but rather on its sides, so as to facilitate its contraction and permanent closure. The main pressure should be in the neighbourhood of the neck of the sac; if the pad presses into the opening, the tendency is to keep the opening patent. The principle of the nipple-shaped pad, frequently ordered for umbilical hernia, is evil; a flat pad properly applied and held in position by an elastic bandage is the proper arrangement for restraining an umbilical hernia. No truss is to be applied until the hernia is completely reduced; it will only do harm by pressing on the contents of the unreduced hernia. In some herniæ, generally those of large size, it is found impossible to keep them up by means of a truss; in such cases an elastic bandage will sometimes effect the object, in others various operations have been recommended. They are spoken of as "the radical cure of hernia," in contradistinction to the so-called "palliative treatment by means of a truss." An attempt has been made above to show that a truss may radically cure a hernia. The principles involved in the operations described are (1) obliteration of the neck of the sac, (3) obliteration of the channel through which the hernia has de-

scended, (3) obliteration of the sac itself, (4) plugging of the channel by invaginating the loose skin. The first and second are specially important, as in them the surgeon imitates nature's way of attempting to cure the tendency to hernial protrusion.

Irreducible Hernia.—Here the main symptom is a tumour in one or other of the situations already referred to, of long standing and generally of large size, in which the contents of the tumour, in whole or in part, cannot be pushed back into the abdomen. The irreducibility is due either to its large size or to changes which have taken place in the contents, either indurations or adhesions. Such a tumour is a constant source of danger: its contents are liable, from their exposed situation, to injury from external violence; it has a constant tendency to increase in size; it may at any time become strangulated, or the contents may inflame, and strangulation may occur secondarily to the inflammation. It is accompanied by dragging sensations referred to the abdomen, colic, dyspepsia, and constipation, which may in its turn lead to obstruction, that is to say, a stoppage of the passage of the contents of that portion of the intestinal canal which lies in the hernial tumour. When an irreducible hernia becomes painful and tender, a local peritonitis has occurred, which resembles in many of its symptoms a case of strangulation.

The treatment of irreducible hernia may be palliative: a bag truss may be worn to prevent the swelling from getting larger; the bowels must be kept open, and all irregularities of diet avoided. A person with such a hernia is in constant danger, and more than palliation is called for. An attempt should be made to reduce the hernia—(1) by laying the patient on his back, raising his buttocks, administering purgatives, and starving him (persevering attention to these points may so reduce the size of the contents that the hernia may be returned); or (2) by means of an elastic bandage carefully applied so as to press continuously on the tumour, and gradually press it back into the abdominal cavity. By this simple means large irreducible herniæ, which have withstood all attempts at reduction, have been returned into the abdomen after elastic pressure has been carefully and continuously applied for a few days. (3) The surgeon may cut down on the hernia, under strict antiseptic precautions, open the sac, divide any omental adhesions, ligature and cut away indurated omentum, return the bowel, and then tie the neck of the sac. Such an operation is unjustifiable unless other means have been fairly tried and failed, and unless the hernia is giving rise to such symptoms that the usefulness of the patient is interfered with.

Strangulated Hernia.—In this the contents are constricted, and the flow of blood into the tumour and from the tumour is stopped. The symptoms are—nausea, vomiting first of bilious matter, after a time of faecal matter, a twisting, burning pain generally referred to the umbilicus, intestinal obstruction, a quick wiry pulse, pain on pressure over the tumour and in the abdomen near the tumour, the abdomen tense and tympanitic, and no impulse on coughing, because the contents of the tumour are practically cut off from the general abdominal contents. The patient has an anxious expression. Sooner or later, from eight hours to eight days, if the strangulation is unrelieved, the tumour will become livid and emphysematous; mortification has occurred, and gangrene of the bowel at the neck of the sac will take place, followed by extravasation of the intestinal contents into the abdominal cavity; the patient becomes collapsed, and dies comatose.

The treatment of a strangulated hernia admits of no delay; delay is fatal. If the symptoms are not very acute, and if the case is seen early, attempts may be made by large enemata and by the application of cold to the tumour to reduce the congested condition and relieve the strangulation. But these attempts must not be persevered with for more than two or three hours. If the strangulation continues, then the patient should be told that his case is one which admits of no delay. Chloroform should be administered; another attempt to return the contents by pressure (termed "the taxis") should be made. If this has already been fairly tried, and if the symptoms indicate urgency, no prolonged attempts at taxis are justifiable, because the condition of the hernial contents may be such that they cannot bear the pressure. The taxis to be successful should be made in a direction opposite to the one in which the hernia has come down. The inguinal hernia should be pressed upwards, outwards, and backwards, the femoral hernia downwards, backwards, and upwards. The larger the hernia the greater is the chance of success. The slightest gurgle indicates that success is near. If taxis does not succeed then the surgeon must cut down on the tumour, carefully dividing the different coverings until he reaches the sac. The sac is then opened, the constriction divided, care being taken not to injure the bowel. The condition of the bowel is then examined, and if it is glistening, however black it may be, it is returned into the abdomen. If it has lost its glistening aspect, if it is like "wet parchment," then the case is very doubtful. If in doubt, relieve the constriction and leave the bowel in the sac. Never open the bowel, however bad it looks; it may recover; and if it does not burst for some hours afterwards, the chances are that adhesions may form at the neck of the sac and lessen the risk

of extravasation into the abdominal cavity—a fœcal fistula will be the result. The omentum, if healthy, may be returned; or if congested and indurated, it may be ligatured and cut off. After the bowel is returned the wound is sewn up, and a pad and flannel bandage applied. A dose of opium should be given to prevent movement of the bowels. On the third day a dose of castor oil is administered if the bowels do not open naturally. A truss is applied after the wound is healed before the patient is allowed to get out of bed. Many complications which may occur cannot here be referred to. Any one suffering from hernia should take great care to obtain an accurately fitting truss, and should remember that, whenever any symptoms resembling in any degree those of strangulation occur, any delay in the treatment is not only dangerous but may prove fatal. A medical man should at once be communicated with. He in his turn has to remember that when a patient asks his advice, complaining of symptoms resembling strangulation, he must examine all the situations where hernia may occur, because the hernial tumour may be so small that it has escaped the notice of the patient. Any assertion on the patient's part that he does not suffer from hernia must receive no weight. The surgeon must satisfy himself by ocular inspection and manual examination. If an operation is necessary he may with confidence say that the operation is not in itself a dangerous one, while, on the other hand, he can assure the patient that any delay is most certainly excessively dangerous. (J. C.)

HERNÖSAND, chief town and seat of the administration of the län of Wester Norrland on the east coast of Sweden, is built on the island of Hernö (connected with the mainland by bridges), about 3 miles south of the mouth of the Angerman river, and 230 miles north of Stockholm. It is the seat of a bishop and possesses a fine church, erected in 1842-46. There are engine works, timber-yards, saw-mills, and various manufactories in the town. The harbour is good. In 1878, 33 vessels, chiefly engaged in the timber trade, with a total burthen of 7698 tons, entered and cleared at the port. Tar is also exported, and there is an institution for pisciculture in the town. Hernösand was founded in 1584, and received its first town privileges from John III. in 1587. The population in 1876 was 4912.

HERO AND LEANDER. Hero, the beautiful priestess of Venus at Sestos, was there seen by Leander, a youth of Abydos, at the celebration of the festival of Venus and Adonis. He became deeply enamoured of her, and found that day an opportunity of declaring his passion, which she returned; and as her position rendered their marriage impossible, they agreed to carry on a clandestine intercourse. Nightly Hero placed a lamp in the top of the tower where she dwelt by the sea, and Leander, guided by it, swam the dangerous Hellespont. One stormy night the lamp was blown out, and Leander perished. On finding his body next morning on the shore, Hero flung herself into the waves.

Reference is made to this famous tale by Virgil (*Georg.*, iii. 253) and by Statius (*Theb.*, vi. 535). Ovid (*Her.*, xviii. and xix.) has composed an epistle from Leander to Hero, and one from Hero to Leander. But the story is best known from the work of Musæus (see *Musæus*), which has been repeatedly translated into modern European languages. The *Hero and Leander* of Marlowe and Chapman is an imitation and expansion of the work of Musæus.

HEROD was the name of a family of Idumæan origin, which displaced the Asmoneans as the rulers of Judæa. The founder of the dynasty, and its most notable representative in every way, was Herod the Great, who was king of the Jews for about thirty-seven years, from 40 to 4 B.C. Herod's father was Antipater, who during the troubles which broke out in the family of Alexander Jannæus, attached himself to Hyrcanus, the weak-minded son of Alexander. In this way Antipater, though an Idumæan, soon became the most powerful man in Judæa, and in the Alexandrian war gave such effectual help to Julius Cæsar that the dictator made him procurator of Judæa, Hyrcanus being high priest (47 B.C.). The same year, at the age of twenty-five, Herod was appointed governor of Galilee by his father. He soon gave proof of the remarkable energy of his character in rooting out the banditti

who infested his province; but his summary measures gave a handle to the enemies of his house at Jerusalem, and he was summoned before the sanhedrin. There he appeared, not in the garb of an accused person, but gorgeously attired, and attended by a guard of soldiers. He found it expedient, however, to withdraw from Jerusalem without awaiting the sentence. He retired to Syria, where he met with a gracious reception from Sextus Cæsar, who appointed him governor of Cœle-Syria. Herod now marched with an army against Jerusalem, but at the persuasion of his father and brother was induced to depart without exacting vengeance on his enemies. After the death of Cæsar, the fortunes of Herod were affected by all the changes which befell the Roman state. When Cassius took the command in the East, and began to gather his strength for the final struggle which was decided at Philippi, Herod managed to win his favour by the readiness with which he raised his share of the heavy exactions imposed upon the East. About the same time his father was poisoned, and to Herod fell the task of avenging his death, as well as of supporting the interests of his house in Palestine. After Philippi he gained Antony over by large presents of money. He and his brother Phasael were appointed tetrarchs of Judæa. In 40 B.C. the Parthians appeared upon the scene, overran the whole of Syria, and placed on the throne of Judæa Antigonus, son of Aristobulus, and representative of the rival branch of the Asmonean house. Herod was completely overpowered; and, after placing his relatives in safety, so far as he could, he hastened to Rome to lay his case before Antony and Octavianus. He succeeded beyond his expectation, for, while he meant only to advocate the claims of Hyrcanus the Asmonean, the two heads of the state made him king of Judæa. Herod returned home without delay, and set about the task of winning the kingdom allotted to him. Owing chiefly to the slackness of the Roman generals who should have helped him, it was three years before he succeeded in taking Jerusalem (37 B.C.). Before that event he had married the beautiful Mariamne, a princess of the Asmonean house, a granddaughter both of Aristobulus and Hyrcanus. Herod's early measures were cruel; he put to death all the members of the sanhedrin except two, and spared no one that was likely to stand in his way. Aristobulus, the youthful brother of Mariamne, whom he had appointed high priest, he caused to be treacherously drowned because he was too popular with the patriotic party. On this occasion Alexandra, mother of Aristobulus, induced Cleopatra to take her part, and Herod had to appear before Antony to answer the charge of murdering the prince. Again Herod knew how to gain the Roman, and he returned home with confirmed power. During the war of Actium, Herod had the good fortune to be engaged in a war with the king of Arabia on Antony's behalf, and so escaped the risk of fighting against Octavianus. Yet he recognized the danger of his position as the friend of Antony, and faced it with his usual courage and foresight. Hastening to Rhodes (30 B.C.), he appeared in the presence of the conqueror, and avowing his loyalty to his friend Antony, proffered the same faithful service to Octavianus. Octavianus was gracious, and remained the constant friend and patron of Herod to the end. This was the last crisis of Herod's life; he was henceforward undisputed king of Judæa, and next to Agrippa the most trusted friend of Augustus. But while the friend of the great, and prosperous in all external relations, Nemesis pursued him in his family. When summoned to answer for himself before Antony, and again on his journey to Rhodes, he left the beautiful and beloved Mariamne in charge of one of his friends, but with the cruel injunction that she should be put to death should anything serious befall himself. On both occasions Mariamne discovered the secret, and, instead

of regarding the command as a proof of his jealous love, abhorred it as another instance of the cruelty which had not spared so many of her nearest relatives. A horrible tragedy ensued: Mariamne openly expressed her disgust; and Herod, furious with rage, jealousy, and rejected love, ordered her death. The violence of his feelings threw him into a dangerous malady, and even drove him to the verge of insanity. His mind never recovered its healthy tone, and in later years the avenger again overtook him. In the meantime his government was marked by the greatest magnificence and apparent success. His turbulent subjects were kept tolerably quiet in spite of heavy taxes. He managed to gratify his love for Greek and Roman life; and yet he avoided wounding too deeply the susceptibilities of the Jews. The magnificent buildings which he raised were the most brilliant products of his reign. He rebuilt Samaria, calling it Sebaste, from the Greek name for Augustus. He converted the small town of Strato's Tower into a magnificent seaport with an artificial harbour, under the name of Cæsarea. These and other towns which he built were furnished with temples, theatres, aqueducts, and all the other ornamental and useful appliances of Greek and Roman life. In the city of Jerusalem even he built a theatre, and an amphitheatre outside of it. A more patriotic work was the rebuilding of the temple (begun 20 B.C.), which had suffered greatly during the late troubles; it was on a very magnificent scale, and lasted nine years and a half, even then being unfinished. Equally necessary and equally significant of his relation to his subjects was the construction of strong fortresses in various parts of the country. The last years of Herod's life were darkened by the return of those family troubles which had previously overcast it. His two sons by Mariamne had been educated at Rome, and returned, 17 B.C., to Judæa. Their Asmonean descent, their youth, beauty, and accomplishments, and their too interesting history gained them the most enthusiastic popularity among the Jews. Their father himself was proud of them. But Pheroras and Salome, brother and sister of Herod, did all they could to sow jealousy and suspicion. Herod's mind was too painfully open to dark insinuations, and he recalled his eldest son Antipater to counterbalance the influence of the Asmonean princes. After the arrival of Antipater, who was a most unscrupulous plotter, there was no more peace or security at the court of Herod; things went from bad to worse, till after many years of the darkest intrigue and the bitterest domestic contention, the two sons of Mariamne were strangled at Sebaste. Soon after the clearest proof was discovered of a conspiracy which Antipater had formed with Pheroras against the life of Herod himself. The order for the death of Antipater was given by Herod from his death-bed. His health had long been failing; after the cruellest torments of both mind and body, he died 4 B.C. The birth of Christ took place in the same year as Herod's death, but this, as is well known, occurred four years before the date fixed as the beginning of the Christian era. The massacre of the little children at Bethlehem is not mentioned by Josephus among the horrors of Herod's last days. He was buried with great magnificence. His will, by which the greater part of his dominions was bequeathed to his sons by Malthace, a Samaritan, was confirmed by Augustus.

Herod's name is doubtless one of the most repulsive in history. He was a man of wonderful energy and sagacity. He saw clearly that Rome was the hinge on which everything turned, and that no policy could be successful which did not depend upon her leading men. His skill in understanding these men, in conciliating them, and making himself useful to them, was very great. Thus he made the successive masters of the world his willing friends, and out of all the crises of his fate emerged victo-

rious. But his hands were red with the blood of his own household; when his position or his interests were touched no scruple could arrest him. All that can be said in his favour is that many of his cruel measures cost him unspeakable agony of mind, and that he was simply more expert than his rivals at the weapons which were in common use in the political life of the time.

The great source for the life of Herod is Josephus; but such writers as Strabo or Dion Cassius are of service in further illustrating it. Useful modern works are Hausrath, *Neubstamentliche Zeitgeschichte*; the work of the same name by Schürer; Ewald, *Geschichte des Volkes Israel*, vol. iv.; Keim, *Geschichte Jesu von Nazara*, vol. i.; and Milman's *History of the Jews*, vol. ii. (T. K.)

HEROD ANTIPAS, son of Herod the Great by the Samaritan Malthace, and full brother of Archelaus, received as his share of his father's dominions the provinces of Galilee and Perea. Like his father, Antipas had a turn for architecture: he rebuilt and fortified the town of Sepphoris; he also fortified Betharamphtha, and called it Julia after the wife of the emperor. Above all he founded the important town of Tiberias on the west shore of the Sea of Galilee, with institutions of a distinctly Greek character. Antipas is mentioned more than once in gospel history under the name of Herod. He it was who was called a "fox" by Christ. He is erroneously spoken of as a king in Mark vi. 14. It was to him that Jesus was sent by Pilate to be tried. But it is in connexion with his wife Herodias that he is best known, and it was through her that his misfortunes arose. He was married first of all to a daughter of Aretas, the Arabian king; but, making the acquaintance of Herodias, the wife of his brother Philip (not the tetrarch), during a visit to Rome, he was fascinated by her and arranged to marry her. Meantime his Arabian wife discovered the plan and escaped to her father, who made war on Herod, and completely defeated his army. John the Baptist condemned his marriage with Herodias, and in consequence was put to death in the way described in the gospels and in Josephus. When Herodias's brother Agrippa was appointed king by Caligula, she was determined to see her husband attain to an equal eminence, and persuaded him, though naturally of a quiet and unambitious temperament, to make the journey to Rome to crave a crown from the emperor. Agrippa, however, managed to influence Caligula against him. Antipas was deprived of his dominions, and banished to Lyons, Herodias voluntarily sharing his exile.

HEROD PHILIP, son of Herod the Great by Cleopatra of Jerusalem, received the tetrarchy of Iturea and other districts to the N.E. of the Jordan. He is a different person from the first husband of Herodias, also called Philip by St Mark (vi. 17), and was married to Salome the daughter of Herodias. Philip is described as an excellent ruler, who loved peace, and was careful to maintain justice, and spent his time in his own territories. He was also a builder of cities, one of which was Cæsarea Philippi, and another was Bethsaida, which he called Julia. He died after a reign of thirty-seven years; and his dominions were incorporated in the province of Syria.

HERODIANS (*Ἡρωδιανοί*), a sect or party mentioned in Scripture as having on two occasions—once in Galilee, and again in Jerusalem—manifested an unfriendly disposition towards Jesus (Mark iii. 6; xii. 13; Matt. xxii. 6; cf. also Mark viii. 15). In each of these cases their name is coupled with that of the Pharisees. According to many interpreters the courtiers or soldiers of Herod Antipas ("Milites Herodis," Jerome; "Diener Herodis," Luther) are intended; but more probably the Herodians were a public political party, who distinguished themselves from the two great historical parties of post-exilic Judaism by the fact that they were and had been sincerely friendly to Herod the Great and to his dynasty (cf. such formations as "Cæsariani," "Pompeiani"). For the evidence which goes

to show that neither the Pharisees nor the Sadducees as such could in consistency have been really thus friendly, reference may be made to Hausrath (especially his *Neu-Testamentliche Zeitgeschichte*, and article "Herodianer" in Schenkel's *Bibel-Lexicon*), and to Wellhausen (*Pharisäer u. Sadducäer*, 1873). It is possible that, to gain adherents, the Herodian party may have been in the habit of representing that the establishment of a Herodian dynasty would be favourable to the realization of the theocracy; and this in turn may suggest some explanation of Tertullian's (*De Præscr.*) palpably absurd allegation that the Herodians regarded Herod himself as the Messiah.

HERODIANUS, the author of a Greek history of the period extending from 180 to 238 A.D. Of his origin and condition in life very little is known. He was in Rome in 203, and seems to have held some public office. It has been conjectured that he was first "procurator Cæsaris" and afterwards "legatus" of the Sicilian provinces, and that, while fulfilling his official duties, he wrote at intervals the history which bears his name. It is entitled Ἡρωδιανοῦ ἱστῆς μετὰ Μάρκων Βασιλείας ἰστοριῶν βιβλία ὀκτώ, and it narrates the events of the fifty-eight years that intervened between the death of Marcus Aurelius and the proclamation of Gordianus III. The narrative is of special value for the reigns of the emperors subsequent to Alexander Severus, with whom the work of Dion Cassius ends. As an historian Herodianus has prominent merits and defects. His work has the value that attaches to a record written by one chronicling the events of his own times, gifted with respectable powers of observation, indubitable candour, and independence of view. But he prefers the interest of style to the interest of truth, and is thus led into exaggerations and errors. The inner life and thought of Rome, the formidable barbarian pressure on her borders, are alike unheeded, that he may blazon his pages with the dazzling vicissitudes of the purple. Though the somewhat sober declamations which he introduces are apt to become tedious, his story is on the whole clear, graceful, and vivacious. The frequent antitheses and studied tricks of phrase savour of the rhetorical schools. Imitations of Thucydides and Latinisms are frequent. Yet in the main his style retains an original cast, a genuine unborrowed beauty, and contrasts favourably with the thin, affected Atticism of the period. Extensive use has been made of Herodianus by later chroniclers. His history was first translated into Latin in the end of the 15th century, by the famous Angelo Poliziano.

HERODIANUS, ÆLIUS, a famous grammarian of antiquity, called by Priscian "maximus auctor artis grammaticæ." He was the son of the grammarian Apollonius, was born at Alexandria, and resided at Rome. He was patronized by the emperor Marcus Aurelius (161–180 A.D.), to whom he dedicated his great treatise on prosody. This was a work in twenty books, called Καθολικὴ Προσῳδία, which included also an account of the etymological part of grammar. An epitome of it has been preserved. Abstracts of a treatise on difficult words and peculiar forms, called Ἐπιμερισμοί, are also extant. Besides these, Herodianus wrote various other treatises; but of the large number of titles quoted, some are probably merely names for parts of larger works. Only one of them has come down complete—a treatise on monosyllables (περὶ μονήρων λέξεως). Numerous quotations, however, and considerable fragments still exist.

Fabricius (*Bibl. Græc.* vi. 278 sqq.) enumerates his works and the passages where they are quoted. Lenz (*Herodiani technici reliquæ*, Lips. 1867–70) has collected and thoroughly edited all the remains.

HERODOTUS, according to the best authorities, was born in or about the year 484 B.C. He was a native of Halicarnassus, a city which belonged originally to the Doric Hexapolis, situated towards the south-western corner

of Asia Minor, but which from a date considerably anterior to the birth of Herodotus had been excluded from the confederacy, and was an isolated Greek town, dependent upon the Persians. Herodotus was thus born a Persian subject, and such he continued until he was thirty or five-and-thirty years of age. At the time of his birth, Halicarnassus was under the rule of a queen called Artemisia, who had been allowed by the Persians to succeed to the sovereignty of her husband, and was mistress, not only of Halicarnassus, but also of Cos, Nisyrus, and Calyndna. The year of her death is unknown; but she left her crown to her son Pisindelis (born about 498 B.C.), who was succeeded upon the throne by his son Lygdamis about the time that Herodotus grew to manhood. The family of Herodotus belonged to the upper rank of the citizens. His father was named Lyxes, and his mother Rhæo, or Dryo. He had a brother Theodore, and an uncle or cousin called Panyasis, who was an epic poet, and a personage of so much importance that the tyrant Lygdamis, suspecting him of treasonable projects, put him to death. It is likely that Herodotus derived from this near relative that love of letters which led him at an early age to the careful study of the existing Greek literature, and determined him ultimately to engage in the composition of his great work. It is probable also that he shared his relative's political opinions, and was either exiled from Halicarnassus, or quitted it voluntarily, at the time of his execution.

Of the education of Herodotus no more can be said than that it was thoroughly Greek, and embraced no doubt the three subjects essential to a Greek liberal education—grammar, gymnastic training, and music. There is no reason to suppose that he went beyond the walls of his native city for instruction in this, the ordinary, curriculum or that he enjoyed any special advantages in respect of these early studies. They would be regarded as completed when he attained the age of eighteen, and took rank among the "ephebi" or "eirenes" of his native city. Under ordinary circumstances a Greek of this age began at once his duties as a citizen, and found in the excitement of political life sufficient employment for his growing energies. But when a city was ruled by a despot or tyrant, this outlet was wanting; no political life worthy of the name existed; and youths of spirit, more especially those of superior abilities, had to cast about for some other field in which to distinguish themselves. Herodotus may thus have had his thoughts turned to literature as furnishing a not unsatisfactory career, and may well have been encouraged in his choice by the example of Panyasis, who, whether his cousin or his uncle, was certainly his elder, and had already gained a reputation by his writings when Herodotus was still an infant. At any rate it is clear from the extant work of Herodotus that he must have devoted himself early to the literary life, and commenced that extensive course of reading which renders him one of the most instructive as well as one of the most charming of ancient writers. The poetical literature of Greece was in his time already large; the prose literature was more extensive than is generally supposed; yet Herodotus shows an intimate acquaintance with the whole of it. He has drunk at the Homeric cistern till his entire being is impregnated with the influence thence derived. The *Iliad* and the *Odyssey* are as familiar to him as Shakespeare to the most highly educated of modern Englishmen. He is acquainted with the poems of the epic cycle, the *Cypria*, the *Epigoni*, &c. He quotes or otherwise shows familiarity with the writings of Hesiod, Olen, Musæus, Bacis, Lysistratus, Archilochus of Paros, Alcæus, Sappho, Solon, Æsop, Aristæus of Proconnesus, Simonidea of Ceos, Phrynichus, Æschylus, and Pindar. He quotes and criticizes Hecataeus, the best of the prose writers who had preceded him, and makes numerous allusions to other authors

of the same class. It may be questioned whether there was any single work of importance in the whole range of extant Greek literature with the contents of which Herodotus had not made himself acquainted by the time that he undertook the composition of his "History."

It must not, however, be supposed that the great Halicarnassian was at any time a mere recluse student. There can be no reasonable doubt that from a very early age his inquiring disposition led him to engage in travels, both in Greece and in foreign countries, which must have been continued year after year for a considerable period, and which made him as familiar with men as with books. He traversed Asia Minor and European Greece in all directions, probably more than once; he visited all the most important islands of the Archipelago,—Rhodes, Cyprus, Delos, Paros, Thasos, Samothrace, Crete, Samos, Cythera, and Ægina. He undertook the long and perilous journey from Sardis to the Persian capital Susa, passed some considerable time at Babylon, and went a voyage to Colchis, and another along the western shores of the Black Sea as far as the estuary of the Dnieper; he travelled in Scythia and in Thrace, visited Zante and Magna Græcia, explored the antiquities of Tyre, coasted along the shores of Palestine, saw Gaza, and made a long stay in Egypt. At the most moderate estimate, his travels covered a space of thirty-one degrees of longitude, or 1700 miles, and twenty-four of latitude, or nearly the same distance. Nor was he content, like the modern tourist, with hasty glimpses of the countries which he visited. At all the more interesting sites he took up his abode for a time; he examined, he inquired, he made measurements, he accumulated materials. Having in his mind the scheme of his great work, he gave ample time to the elaboration of all its parts, and took care to obtain by personal observation a full knowledge of all the various countries which were to form the scene of his narrative.

The travels of Herodotus seem to have been chiefly accomplished between his twentieth and his thirty-seventh year (464–447 B.C.). It was probably in his early manhood that as a Persian subject he visited Susa and Babylon, taking advantage of the Persian system of posts which he describes in his fifth book. His residence in Egypt must, on the other hand, have been subsequent to 460 B.C., since he saw the skulls of the Persians slain by Inarus in that year. Skulls are rarely visible on a battlefield for more than two or three seasons after the fight, and we may therefore presume that it was during the reign of Inarus (460–454 B.C.), when the Athenians had great authority in Egypt, that he visited the country, making himself known as a learned Greek, and therefore receiving favour and attention on the part of the Egyptians, who were so much beholden to his countrymen. On his return from Egypt, as he proceeded along the Syrian shore, he seems to have landed at Tyre, and from thence to have gone to Thasos, which lay off the coast of Thrace. His Scythian travels are thought to have taken place prior to 450 B.C.

It is a question of some interest from what centre or centres these various expeditions were made. Up to the time of the execution of Panyasis, which is placed by chronologists in or about the year 457 B.C., there is every reason to believe that Halicarnassus was the historian's home; and thus we may assume that, for some seven or eight years, that city was the point from which he started and to which he returned. His travels in Asia Minor, in European Greece, and among the islands of the Ægean probably belong to this period, as does also his journey to Susa and Babylon. We are told that when he quitted Halicarnassus on account of the tyranny of Lygdamis, in or about the year 457 B.C., he took up his abode in Samos. That island was an important member of the Athenian confederacy, and in making it his home Herodotus would have

put himself under the protection of Athens. The fact that Egypt was then largely under Athenian influence may have induced him to proceed, in 457 or 456 B.C., to that country. The complete knowledge that he has of the whole of Egypt indicates a stay there of some years, and it was perhaps not till 454 B.C. that he returned to his Samian home. The stories that he had heard in Egypt of Scosotris may then have stimulated him to make voyages from Samos to Colchis, Scythia, and Thrace. When he had seen these countries, he had made acquaintance with almost all the regions which were to be the scene of his projected history, and could apply himself to the task of its composition with the comfortable feeling that he possessed all the local knowledge requisite for graphic and telling description.

After Herodotus had resided for some seven or eight years in Samos, events occurred in his native city which induced him to return thither. The tyranny of Lygdamis had gone on from bad to worse, and at last the citizens rose in rebellion against him, and he was expelled. According to Suidas, Herodotus was himself an actor, and indeed the chief actor, in the enterprise; but no other author confirms this statement, which is intrinsically improbable. It is certain, however, that a revolt broke out, that Lygdamis was dethroned, and that Halicarnassus became a voluntary member of the Athenian confederacy, to which it continued thenceforth attached. Herodotus would now naturally return to his native city, and enter upon the enjoyment of those rights of free citizenship on which every Greek set a high value. He would also, if he had by this time composed his history, or any considerable portion of it, begin to make it known by recitation among his friends and acquaintance. There is reason to believe that these first attempts to push himself into notice were not received with much favour,—the prophet did not obtain honour in his own country,—his countrymen ridiculed the work which they had been expected to admire; and the disappointed author, chagrined at his failure, precipitately withdrew from his native town, and sought a refuge in Greece proper (about 447 B.C.).

A writer of late date (125–200 A.D.) and low credit, Lucian of Samosata, in one of his rhetorical pieces, declares that on quitting Halicarnassus Herodotus proceeded straight to Olympia, and finding the quadriennial festival in progress recited his work to the assembled multitudes, who were highly delighted with it, and freely expressed their admiration. The statement, however, is improbable, and is rejected by most critics, who point out with reason the unsuitability of the work for recitation before an assemblage of persons from all parts of Greece, and call attention to the suspicious circumstance that the story is first told 600 years after the time of its supposed occurrence. From earlier and better writers we learn that Athens was the place to which the disappointed author betook himself, and that he appealed from the verdict of his countrymen to Athenian taste and judgment. By recitations held in that city he made his work known to the best Grecian intellects, and won such approval that in the year 445 B.C., on the proposition of a certain Anytus, he was voted a sum of ten talents (£2400) by decree of the people. At one of the recitations Thucydides was present with his father, Olorus, and was so moved that he burst into tears, whereupon Herodotus remarked to the father—"Olorus, your son has a natural enthusiasm for letters."

Athens was at this time the centre of intellectual life, and could boast a galaxy of talent such as has rarely been gathered together either before or since. The stately Pericles, his clever rival Thucydides the son of Melesias, the fascinating Aspasia, the eloquent Antiphon, the scientific musician Damon, the divine Phidias, Protagoras the subtle disputant, Zeno the inventor of logic, the jovial yet bitter

Cratinus, the gay Crates, Euripides the master of pathos, Sophocles the most classic even of the ancients, formed a combination of which even Athens might be proud, and which must have charmed the literary aspirant. Accepted into this brilliant society, on familiar terms with all probably, as he certainly was with Olorus, Thucydides, and Sophocles, he cannot but have found his Attic sojourn delightful, and have been tempted, like many another foreigner, to make Athens his permanent home. It is to his credit that he did not yield to this temptation. At Athens he must have been a dilettante, an idler, without political rights or duties, a mere literary man. As such he would have soon ceased to be respected in a society where literature was not recognized as a separate profession, where a Socrates served in the infantry, and a Sophocles commanded fleets, and a Thucydides was general of an army, and an Antiphon was for a time at the head of the state. Men were not men according to Greek notions unless they were citizens; and Herodotus, aware of this, probably sharing in the feeling, was anxious, having lost his political status at Halicarnassus, to obtain such status elsewhere. At Athens the franchise, jealously guarded at this period, was not to be attained without great expense and difficulty. Accordingly, in the year 444 B.C., on the scheme of sending a colony to Thurii in Italy being broached by Pericles, Herodotus was among those who gave in their names; and in the spring of the following year he sailed from Athens to Italy with the other colonists, and became a citizen of the new town.

From this point of his career, when he had reached the age of forty, we lose sight of Herodotus almost wholly. He seems to have made but few journeys, one to Crotona, one to Metapontum, and one to Athens (about 430 B.C.) being all that his work indicates. No doubt he was employed mainly, as Pliny testifies, in retouching and elaborating his general history. He may also have composed at Thurii that special work on the history of Assyria to which he twice refers in his first book, and which is quoted by Aristotle. It has been supposed by many that he lived to a great age, and argued that "the never-to-be-mistaken fundamental tone of his performance is the quiet talkativeness of a highly cultivated, tolerant, intelligent, *old man*" (Dahlmann). But the indications derived from the later touches added to his work, which form the sole evidence on the subject, would rather lead to the conclusion that his life was not very prolonged. There is nothing in the nine books which may not have been written as early as 430 B.C.; there is no touch which, even probably, points to a later date than 424 B.C. As the author was evidently engaged in polishing up his work to the last, and even promises touches which he does not give, we may assume that he did not much outlive the date last mentioned, or in other words, that he died at about the age of sixty. The predominant voice of antiquity tells us that he died at Thurii, where his tomb was shown in later ages.

In estimating the great work of Herodotus, and his genius as its author, it is above all things necessary to conceive aright what that work was intended to be. It has been called "a universal history," "a history of the wars between the Greeks and the barbarians," and "a history of the struggle between Greece and Persia." But these titles are all of them too comprehensive. Herodotus, who omits wholly the histories of Phoenicia, Carthage, and Etruria, three of the most important among the states existing in his day, cannot have intended to compose a "universal history," the very idea of which belongs to a later age. He speaks in places as if his object was to record the wars between the Greeks and the barbarians; but as he omits the Trojan war, in which he fully believes, the expedition of the Teucrians and Mysians against Thrace

and Thessaly, the wars connected with the Ionian colonization of Asia Minor, and others, it is evident that he does not really aim at embracing in his narrative all the wars between Greeks and barbarians with which he was acquainted. Nor does it even seem to have been his object to give an account of the entire struggle between Greece and Persia. That struggle was not terminated by the battle of Mycale and the capture of Sestos in 479 B.C. It continued for thirty years longer, to the peace of Callias. The fact that Herodotus ends his history where he does shows distinctly that his intention was, not to give an account of the entire long contest between the two countries, but to write the history of a particular war—the great Persian war of invasion. His aim was as definite as that of Thucydides, or Schiller, or Napier, or any other writer who has made his subject a particular war; only he determined to treat it in a certain way. Every partial history requires an "introduction;" Herodotus, untrammelled by examples, resolved to give his history a magnificent introduction. Thucydides is content with a single introductory book, forming little more than one-eighth of his work; Herodotus has six such books, forming two-thirds of the entire composition.

By this arrangement he is enabled to treat his subject in the *grand* way, which is so characteristic of him. Making it his main object in his "introduction" to set before his readers the previous history of the two nations who were the actors in the great war, he is able in tracing their history to bring into his narrative some account of almost all the nations of the known world, and has room to expatiate freely upon their geography, antiquities, manners and customs, and the like, thus giving his work the "universal" character which has been detected in it, and securing for it, without trenching upon unity, that variety, richness, and fulness which are a principal charm of the best histories, and of none more than his. In tracing the growth of Persia from a petty subject kingdom to a vast dominant empire, he has occasion to set out the histories of Lydia, Media, Assyria, Babylon, Egypt, Scythia, Thrace, and to describe the countries and the peoples inhabiting them, their natural productions, climate, geographical position, monuments, &c.; while, in noting the contemporaneous changes in Greece, he is led to tell of the various migrations of the Greek race, their colonies, commerce, progress in the arts, revolutions, internal struggles, wars with one another, legislation, religious tenets, and the like. The greatest variety of episodic matter is thus introduced; but the propriety of the occasion and the mode of introduction are such that no complaint can be made—the episodes never entangle, encumber, or even unpleasantly interrupt the main narrative.

The most important quality of a historian is trustworthiness; for a professed history is of no value unless we can place reliance upon its truth. It has been questioned, both in ancient and in modern times, whether the history of Herodotus possesses this essential requisite. Several ancient writers call his veracity in question, accusing him of the crime of conscious and intentional untruthfulness. Moderns generally acquit him of this charge; but his severer critics still urge that, from the inherent defects of his character, his credulity, his love of effect, and his loose and inaccurate habits of thought, he was unfitted for the historian's office, and has produced a work of but small historical value. It is impossible, within the limits of an article such as the present, to enter fully upon this controversy. Perhaps it may be sufficient to remark that the defects in question certainly exist, and detract to some extent from the authority of the work, more especially of those parts of it which deal with remoter periods, and were taken by Herodotus on trust from his informants, but that

they only slightly affect the portions which treat of later times and form the special subject of his history. In confirmation of this view, it may be noted that the authority of Herodotus for the circumstances of the great Persian war, and for all local and other details which come under his immediate notice, is accepted by even the most sceptical of modern historians, and forms the basis of their narratives.

Among the merits of Herodotus as an historian, the most prominent are the diligence with which he has collected the materials for his history, the candour and impartiality with which he has placed his facts before the reader, the political dispassionateness which he displays in the judgments that he passes upon party leaders, the absence of undue national vanity, and the breadth of his conception of the historian's office, which makes his work a storehouse of diversified knowledge for which the student of antiquity can never be sufficiently grateful. On the other hand, he has no claim to rank as a critical historian; he has no conception of the philosophy of history, no insight into the real causes that underlie political changes, no power of penetrating below the surface, or even of grasping the real interconnection of the events which he describes. He belongs distinctly to the romantic school; his forte is vivid and picturesque description, the lively presentation to the reader of scenes and actions, characters and states of society, not the subtle analysis of motives, or the power of detecting the undercurrents which sway events, or the generalizing faculty which draws lessons from history and makes the past illumine the darkness of the future.

But it is as a writer that the merits of Herodotus are most conspicuous and most unquestioned. "O that I were in a condition," says Lucian, "to resemble Herodotus, if only in some measure! I by no means say in all his gifts, but only in some single point; as, for instance, the beauty of his language, or its harmony, or the natural and peculiar grace of the Ionic dialect, or his fulness of thought, or by whatever name those thousand beauties are called which to the despair of his imitator are united in him." Cicero calls his style "copious and polished;" Quintilian, "sweet, pure, and flowing;" Longinus says he was "the most Homeric of historians;" Dionysius, his countryman, prefers him to Thucydides, and regards him as combining in an extraordinary degree the excellencies of sublimity, beauty, and the true historical method of composition. Moderns are almost equally complimentary. "The style of Herodotus," says one, "is universally allowed to be remarkable for its harmony and sweetness." "The charm of his style," argues another, "has so dazzled men as to make them blind to his defects." Various attempts have been made to analyse the nature of the charm which is so universally felt; but it may be doubted whether any of them are very successful, whether the aroma of the flower does not evaporate in the critic's alembic. All, however, seem to agree that among the qualities for which the style of Herodotus is to be admired are simplicity, freshness, naturalness, and harmony of rhythm. Master of a form of language peculiarly sweet and euphonical, and possessed of a delicate ear which instinctively suggested the most musical arrangement possible, he gives his sentences, without art or effort, the most agreeable flow, is never abrupt, never too diffuse, much less prolix or wearisome, and being himself simple, fresh, *naïf* (if we may use the word), honest, and somewhat quaint, he delights us by combining with this melody of sound simple, clear, and fresh thoughts, perspicuously expressed, often accompanied by happy turns of phrase, and always manifestly the spontaneous growth of his own fresh and unsophisticated mind. Reminding us in some respects of the quaint mediæval writers, Froissart and Philippe de Comines, he greatly excels them, at once in the beauty of his language and the art with which he has com-

bined his heterogeneous materials into a single perfect harmonious whole.

As might have been expected from its excellence, the history of Herodotus has been translated by many persons and into many languages. About 1450, at the time of the revival of learning, a Latin version was made and published by Laurentius Valla. This was revised in 1537 by Hensbach, and accompanies the Greek text of Herodotus in many editions. The first complete translation into a modern language was the English one of Littlebury, published in 1737. This was followed in 1786 by the French translation of Larcher, a valuable work, accompanied by copious notes and essays. Beloe, the second English translator, based his work on that of Larcher. His first edition, in 1791, was confessedly very defective; the second, in 1806, still left much to be desired. A good German translation, but without note or comment, was brought out by Friedrich Lange at Berlin in 1811. Andrea Mustoxidi, a native of Corfu, published an Italian version in 1820. In 1822 Auguste Miot endeavoured to improve on Larcher; and in 1828-32 Dr Adolf Schöll brought out a German translation with copious notes (new ed., 1855), which has to some extent superseded the work of Lange. About the same time a new English version was made by Mr Isaac Taylor (London, 1829). Finally, in 1858-60, the history of Herodotus was translated by Canon Rawlinson, assisted in the copious notes and appendices accompanying the work by Sir Gardner Wilkinson and Sir Henry Rawlinson. More recently we have translations in German by Bähr (Stuttgart, 1867) and Stein (Oldenburg, 1875); in French by Giguet (1857) and Talbot (1864); and in Italian by Ricci (Turin, 1871-76), Grandi (Asti, 1872), and Bertini (Naples, 1871-2). A Swedish translation by F. Carlstadt was published at Stockholm in 1871.

The best recent editions of the Greek text of Herodotus are the following:—*Herodoti Historiæ*, ed. Schweighäuser, 5 vols. 8vo, Strasburg, 1816; *Herodoti Halicarnassæ Historiarum libri IX.*, ed. Gaisford, Oxford, 1840; *Herodotus, with a Commentary*, by J. W. Blakesley, B.D., 2 vols. 8vo, London, 1854; *Herodoti Musæ*, ed. Bähr, 4 vols. 8vo, Leipsic, 1856-61, 2d ed.; *Herodoti Historia*, ed. Abicht, 2 vols. 8vo, Leipsic, 1869; and *Herodoti Historiæ*, ed. H. Stein, 2 vols., 1869-71. Among works of value illustrative of Herodotus may be mentioned Bouhier, *Recherches sur Hérodote*, Dijon, 1746; Rennell, *Geography of Herodotus*, London, 1800; Niebuhr, *Geography of Herodotus and Scythia*, Eng. trans., Oxford, 1830; Dohmann, *Herodot, aus seinem Buche sein Leben*, Altona, 1823; *Questions Herodotæ*, Leipsic, 1841; Kenrick, *Egypt of Herodotus*, London, 1841; Mure, *Literature of Greece*, vol. iv., London, 1852; Abicht, *Uebersicht über den Herodotischen Dialect* (Leipsic, 1869, 3d ed. 1874), and *De codicum Herodoti fide ac auctoritate* (Naumburg, 1869); Melander, *De anacoluthis Herodoteis* (Lund, 1869); Matzat, "Ueber die Glaubwürdigkeit der geograph. Angaben Herodots über Asien," in *Hermes*, vi.; Büdinger, *Zur ägyptischen Forschung Herodots* (Vienna, 1873, reprinted from the *Sitzungsber.* of the Vienna Acad.); Merzdorf, *Questiones grammaticæ de dialecto Herodotæ* (Leipsic, 1875); A. Kircl'off, *Ueber die Entstehungszeit des Herodotischen Geschichtswerk* (Berlin, 1878); and Adolf Bauer, *Herodoti Biographie* (Vienna, 1878). For notices of current literature see Bursian's *Jahresbericht*. Students of the original may also consult with advantage the lexicons of Æmilius Portus (Oxford, 1817) and of Schweighäuser (London, 1824). (G. R.)

HÉROLD, LOUIS JOSEPH FERDINAND (1791-1833), French musician, was born in Paris, January 28, 1791, the son of François Joseph Hérold, an accomplished pianist, who, however, did not at first wish his son to adopt the musical profession. It was indeed not till after his father's death that Hérold in 1806 entered the Paris conservatoire, where he studied under Catel and Méhul, one of the leading composers of the time, by whose teaching his pupil profited soon and permanently. In 1812 he gained the grand prix de Rome (a travelling scholarship awarded by the French Government to the best pupils of the conservatoire), and accordingly started for Italy, where he remained till 1815, and composed a symphony, a cantata, and several pieces of chamber music. It was also during his stay in Italy that Hérold for the first time ventured on the stage with the opera *La Gioventù di Enrico V.*, first performed at Naples in 1815 with moderate success. Returning to Paris he had the good fortune to be invited by Boieldieu to participate in the composition of an opera called *Charles de France*, performed in 1816, and soon followed by Hérold's first French opera, *Les Rosières* (1817), which was received very favourably. Of the numerous dramatic works which Hérold produced for

the next fifteen years in rapid succession it is unnecessary to give a detailed account. Only the names of some of the more important may be mentioned here:—*La Clochette* (1817), *L'Auteur mort et vivant* (1820), *Marie* (1826), and the ballets *La Fille mal Gardée* (1828) and *La Belle au bois dormant* (1829). Hérold also wrote a vast quantity of piano-forte music of a more or less ephemeral kind, in spite of his time being much occupied by his duties as accompanist at the Italian opera in Paris. In 1831 he produced one of the two works which have given immortality to his name, the romantic opera *Zampa*, which has met with immense success not only in France but also in Germany, where it has kept the stage till the present day, and is considered Hérold's masterpiece. In France that eminence is justly accorded to the *Le Pré aux Clercs* (first performance December 15, 1832), in every way a representative work of the French school, in which French *esprit* and French chivalry find their most perfect embodiment. Grace, liveliness, and true dramatic spirit are Hérold's best qualities, and secure him a prominent place amongst the composers of *opéra comique*, in the more refined sense which has been lost by most composers of modern France. Hérold died January 19, 1833, of the lung disease from which he had suffered for many years, and the effects of which he accelerated by incessant work.

HERON, or HERO, a mathematician and natural philosopher of Alexandria, was the pupil of Ctesibius, and flourished probably about a century or a century and a half before Christ. His name has been preserved in the well-known experiment of Hero's fountain, in which, by means of condensed air, water is made to spring from a jet in a continuous stream. Several of Heron's writings are entirely lost, and of those that remain some have never been printed. His most valuable work is that on *Pneumatics*, in which are given his experiments on the elasticity of the air and of steam. His *Mechanics* and *Barulcus* treat of the subjects which would now be comprised in an elementary book on dynamics. At the end of his *Catapultica* or *Belopoietica*, which are probably the same, occurs Heron's solution of the ancient and much discussed problem to find two mean proportionals between two given straight lines. *Cheirobalistra*, *Cambestria*, *Camarica*, *Automata*, are the titles of some of his other physical works. His mathematical works (see Hultsch's *Heronis Alexandrini Geometricorum et Stereometricorum Reliquie*, Berlin, 1864) are very fragmentary, and it is difficult to determine whether several of them are not to be attributed to later and anonymous writers. Heron seems to have been the first to show how the area of a triangle may be found from its three sides. See two papers by Vincent and Boncompagni in *Bullettino di bibliogr. e di storia delle scienze matem. e fisiche*, iv.

HERON, called the younger, to distinguish him from his namesake of Alexandria, was, like him, a mathematician and natural philosopher. By some he is supposed to have flourished in the first half of the 7th century A.D.; by others, with more probability, to have lived at Constantinople in the 10th century. He wrote a treatise on *Besieging Engines* which still exists, and another on the *Construction of Sun-dials*, which is now lost. Some mathematical writings assigned to him should perhaps be referred to Heron the elder (see *Mémoires Présentés à l'Académie des Inscriptions*, 1^{re} série, tome iv., Paris, 1854).

HERON—French, *Héron*; Italian, *Aghirone*, *Airone*; Latin, *Ardea*; Greek, *ἑρδιός*; Anglo-Saxon, *Hragra*; Icelandic, *Hegre*; Swedish, *Häger*; Danish, *Heire*; German, *Heiger*, *Reiher*, *Heergans*; Dutch, *Reiger*—a long-necked, long-winged, and long-legged bird, the representative of a very natural group, the *Ardeide*, which through the neglect or ignorance of ornithologists has been for many years encumbered by a considerable number of alien forms.

belonging truly to the Cranes, *Gruide* (see vol. vi. p. 546), and Storks, *Ciconiide*, whose structure and characteristics are wholly distinct, however much external resemblance some of them may possess to the Herons. Eliminating these intruders, it is difficult or even impossible to estimate with any accuracy the number of species of *Ardeide* which exist. Professor Schlegel in 1863 enumerated 61, besides 5 of what he terms "conspecies," as contained in the collection at Leyden (*Mus. des Pays Bas, Ardeæ*, 64 pp.),—on the other hand, G. R. Gray in 1871 (*Hand-list, &c.*, iii. pp. 26–34) admitted above 90, while Dr Reichenow (*Journ. für Ornithologie*, 1877, pp. 232–275) recognizes 67 as known, besides 15 "subspecies" and 3 varieties, arranging them in 3 genera, *Nycticorax*, *Botaurus*, and *Ardea*, with 17 subgenera. But it is difficult to separate the Family, with any satisfactory result, into genera, if structural characters have to be found for these groups, for in many cases they run almost insensibly into each other—though in common language it is easy to speak of Herons, Egrets, Bitterns, Night-Herons, and Boatbills. With the exception of the last, Professor Schlegel retains all in the

FIG. 1.—Heron.

genus *Ardea*, dividing it into eight sections, the names of which may perhaps be Englished—Great Herons, Small Herons, Egrets, Semi-egrets, Rail-like Herons, Little Bitterns, Bitterns, and Night-Herons. It may be expedient here to adopt this arrangement, though the present writer would guard himself against being supposed to give it more than partial and provisional assent.

The common Heron of Europe, *Ardea cinerea* of Linnæus, is universally allowed to be the type of the family, and it may also be regarded as that of Professor Schlegel's first section. The species inhabits suitable localities throughout the whole of Europe, Africa, and Asia, reaching Japan, many of the islands of the Indian Archipelago, and even Australia. Though by no means so numerous as formerly in Britain, it is still sufficiently common to render a description of it almost unnecessary,¹ and there must be few persons who have not seen it rising slowly from some riverside or marshy flat, or passing overhead in its lofty and

¹ In many parts of England it is generally called a "Hernser"—being a corruption of "Heronsewe," which, as Professor Skeat states (*Etymol. Dictionary*, p. 264), is a perfectly distinct word from "Heronshaw," commonly confounded with it. The further corruption of "Hernser" into "handsaw," as in the well-known proverb, was easy in the mouth of men to whom hawking the Heronsewe was unfamiliar.

leisurely flight on its way to or from its daily haunts; while they are many who have been entertained by watching it as it sought its food, consisting chiefly of fishes (especially eels and flounders) and amphibians—though young birds and small mammals come not amiss—wading midge in the shallows, swimming occasionally when out of its depth, or standing motionless to strike its prey with its formidable and sure beak. When sufficiently numerous the Heron breeds in societies, known as Heronries, which of old time were protected both by law and custom in nearly all European countries, on account of the sport their tenants afforded to the falconer. Of late years, partly owing to the withdrawal of the protection they had enjoyed, and still more, it would seem, from agricultural improvement, which, by draining meres, fens, and marshes, has abolished the feeding-places of a great population of Herons, many of the larger Heronries have broken up—the birds composing them dispersing to neighbouring localities and forming smaller settlements, most of which are hardly to be dignified by the name of Heronry, though commonly accounted such. Thus the number of so-called Heronries in the United Kingdom, and especially in England and Wales, has become far greater than formerly, but no one can doubt that the number of Herons has dwindled. Mr Harting, after being at great pains to collect statistics on the subject, gave, in 1872 (*Zoologist*, s.s. pp. 3261–3272; with additions and corrections, pp. 3404–3407), a list of those existing in the three kingdoms, more than 200 in number, of which a little over one-half are in England and Wales, more than 50 in Scotland, and nearly 50 in Ireland. The sites chosen by the Heron for its nest vary greatly. It is generally built in the top of a lofty tree, but not unfrequently (and this seems to have been much more usual in former days) near or on the ground among rough vegetation, on an island in a lake, or again on a rocky cliff of the coast. It commonly consists of a huge mass of sticks, often the accumulation of years, lined with twigs, and in it are laid from four to six sea-green eggs. The young are clothed in soft flax-coloured down, and remain in the nest for a considerable time, therein differing remarkably from the “pipers” of the Crane, which are able to run almost as soon as they are hatched. The first feathers assumed by young Herons in a general way resemble those of the adult, but the fine leaden-grey back, the pure white breast, the black throat-streaks, and especially the long pendent plumes, which characterize only the very old birds, and are most beautiful in the cocks, are subsequently acquired. The Heron measures about 3 feet from the bill to the tail, and the expanse of its wings is sometimes not less than 6 feet, yet it weighs only between 3 and 4 lb.

Large as is the common Heron of Europe, it is exceeded in size by the Great Blue Heron of America, *Ardea herodias*, which generally resembles it in appearance and habits, and both are smaller than the *A. sumatrana* or *A. typhon* of India and the Malay Archipelago, while the *A. goliath*, of wide distribution in Africa and Asia, is the largest of all. The Purple Heron, *A. purpurea*, as a well-known European species having a great range over the Old World, also deserves mention here. Of the species included in Professor Schlegel's second section, little need now be said. They inhabit the tropical parts of Africa, Australasia, and America. The Egrets, forming his third group, require more notice, distinguished as they are by their pure white plumage, and, when in breeding-dress, by the beautiful dorsal tufts of decomposed feathers that ordinarily droop over the tail, and are so highly esteemed as ornaments by Oriental magnates. The largest species is *A. occidentalis*, only known apparently from Florida and Cuba; but one not much less, the Great Egret, *A. alba*, belongs to the Old World, breeding regularly in south-eastern Europe,

and occasionally straying to Britain. A third, *A. egretta*, represents it in America, while much the same may be said of two smaller species, *A. garzetta*, the Little Egret of English authors, and *A. candidissima*; and a sixth, *A. intermedia*, is common in India, China, and Japan, besides occurring in Australia. The group of Semi-egrets, containing some nine or ten forms, among which the Buff-backed Heron, *A. bubulcus*, is the only species that is known to have occurred in Europe, is hardly to be distinguished from the last section except by their plumage being at certain seasons varied in some species with slaty-blue and in others with rufous. The Rail-like Herons form Professor Schlegel's next section, but it can scarcely be satisfactorily differentiated, and the epithet is misleading, for its members have no Rail-like affinities, though the typical species, which inhabits the south of Europe, and occasionally finds its way to England, has long been known as *A. ralloides*.¹ Nearly all these birds are tropical or subtropical. Then there is the somewhat better defined group

FIG. 2.—Bittern.

of Little Bitterns, containing about a dozen species—the smallest of the whole family. One of them, *A. minuta*, though very local in its distribution, is a native of the greater part of Europe, and has bred in England. It has a close counterpart in the *A. exilis* of North America, and is represented by three or four forms in other parts of the world, the *A. pusilla* of Australia especially differing very slightly from it. Ranged by Professor Schlegel with these birds, which are all remarkable for their skulking habits, but more resembling the true Herons in their nature, are the common Green Bittern of America, *A. virescens*, and its very near ally the African *A. atricapilla*, from which last it is almost impossible to distinguish the *A. javanica*, of wide range throughout Asia and its islands, while other species, less closely related, occur elsewhere as *A. javanicollis*,—one form of which, *A. gouldi*, inhabits Australia.

The true Bitterns, forming the genus *Botaurus* of most authors, seem to be fairly separable, but more perhaps on account of their wholly nocturnal habits and correspondingly adapted plumage than on strictly structural grounds, though some differences of proportion are observable. The

¹ It is the “Squacco-Heron” of modern British authors—the distinctive name, given “Squacco” by Willughby and Ray from *Aldrovandus*, having been misspelt by Latham.

common Bittern of Europe, *B. stellaris*, was formerly an abundant bird in many parts of Britain; but, since the reclamation of the bogs and fens it used to inhabit, it is become only an irregular visitant,—though not a winter passer without its appearing in some numbers, when its uncommon aspect, its large size, and beautifully pencilled plumage cause it to be regarded as a great prize by the lucky gun-bearer to whom it falls a victim. Its value as a delicacy for the table, once so highly esteemed, has long vanished. The old fable of this bird inserting its beak into a reed or plunging it into the ground, and so causing the booming sound with which its name will be always associated, is also exploded, and nowadays indeed so few people in Britain have ever heard its loud and awful voice, which seems to be uttered only in the breeding-season, and is therefore unknown in a country where it no longer breeds,¹ that incredulity as to its booming at all has in some quarters succeeded the old belief in this as in other reputed peculiarities of the species. The Bittern is found from Ireland to Japan, in India, and throughout the whole of

FIG. 3.—Boatbill.

Africa—suitable localities being, of course, understood. Australia and New Zealand have a kindred species, *B. pacificus*, and North America a third, *B. mugitans* or *B. lentiginosus*. The former is said to bellow like a bull, but authorities differ as to the vocal powers of the latter,² which has several times wandered to Europe, and is distinguishable by its smaller size and uniform greyish-brown primaries, which want the tawny bars that characterize *B. stellaris*. Nine other species of Bitterns from various parts of the world are admitted by Professor Schlegel, but some of them should perhaps be excluded from the genus *Botaurus*.

Of the Night-Herons the same author recognizes six species, all of which may be reasonably placed in the genus *Nycticorax*, characterized by a shorter beak and a few other peculiarities, among which the large eyes deserve mention. The first is *N. griseus*, a bird widely spread over the Old World, and not unfrequently visiting England, where it would undoubtedly breed if permitted. Professor Schlegel unites with it the common Night-Heron of America; but

¹ The last-recorded instance of the Bittern breeding in England was in 1868, as mentioned by Mr Stevenson (*Birds of Norfolk*, ii. p. 164). All the true Bitterns, so far as is known, lay eggs of a light olive-brown colour.

² Richardson, a most accurate observer, positively asserts (*Fauna Boreali-Americana*, ii. p. 374) that its booming exactly resembles that of its Old-World congener, but American ornithologists seem only to have heard the croaking note it makes when disturbed.

this, though very closely allied, is generally deemed distinct, and is the *N. naevius* or *N. gardeni* of most writers. A clearly different American species, with a more southern habitat, is the *N. violaceus* or *N. cayennensis*, while others are found in South America, Australia, some of the Asiatic Islands, and in West Africa. The Galapagos have a peculiar species, *N. pauper*, and another, so far as is known, peculiar to Rodriguez, *N. megacephalus*, existed in that island at the time of its being first colonized, but is now extinct.

The Boatbill, of which only one species is known, seems to be merely a Night-Heron with an exaggerated bill,—so much widened as to suggest its English name,—but has always been allowed generic rank. This curious bird, the *Cancroma cochlearia* of most authors, is a native of tropical America, and what is known of its habits shews that they are essentially those of a *Nycticorax*.³

Bones of the common Heron and Bittern are not uncommon in the peat of the East-Anglian fens. Remains from Sansan and Langy in France have been referred by M. Alphonse Milne-Edwards to Herons under the names of *Ardea perplexa* and *A. formosa*; a tibia from the Miocene of Steinheim by Dr Fraas to an *A. similis*, while Professor Owen recognized a portion of a sternum from the London Clay as most nearly approaching this Family.

It remains to say that the Herons form part of Professor Huxley's section *Pelargomorpha*, belonging to his larger group *Desmognathæ*, and to draw attention to the singular development of the patches of "powder-down" which in the family *Ardeidae* attain a magnitude hardly to be found elsewhere. Their use is utterly unknown. (A. N.)

HEROPHILUS. See ANATOMY, vol. i. p. 801-2.

HERRERA, FERNANDO DE (1534-1597), lyrical poet, born at Seville in 1534. Although an ecclesiastic, he addressed his verses to an Andalusian lady, said to have been the countess of Gelvez, under different names; but his love was as Platonic as Petrarch's, and served only to lend additional beauty and tenderness to his poems. Herrera has been celebrated in a sonnet by Cervantes; and his poems were taken as models by the later poet, Lope de Vega. He died at Seville in 1597. Flourishing at a time when the Castilian language was not yet ripe for the higher lyrical efforts, Herrera endeavoured to remedy the defects of his native tongue by expelling from poetry the more vulgar and trivial words, by introducing words in their place from Greek, Latin, and Italian, and by employing unfamiliar inflexions and inverted constructions so as to approach more nearly the model of the classical tongues. His system, however, was theoretical and artificial, and not inspired by any genuine impulse of taste, so that in many instances where he strives to be elevated and correct, he succeeds only in being affected and formal.

Herrera published his critical views in 1580, in able notes to the works of Garcilaso, whose Italian style he followed in a volume of poems which appeared in 1582. Of these the sonnets are poor, the elegies good, and the sixteen canzones or odes best of all. The finest of these last are perhaps the two on the battle of Lepanto and on the overthrow of Sebastian of Portugal. The Pindaric ode on sleep has been frequently praised. Pacheco, the painter, published additional poems of Herrera in 1619; and Fernandez added still more in the fourth and fifth volumes of his *Poetas Castellanos*, in 1808. *The Battle of the Giants*, *The Rape of Proserpine*, *The Amadis*, and *The Loves of Laurino and Cærona* are among the titles of longer poems of Herrera which are now lost. Of his prose works the chief are the *Relacion de la Guerra de Chipre y batalla de Lepanto*, 1572; and the *Vida y muerte de Tomas Moro*, 1592, translated from Stapleton's Latin *Lives of the Three Thomases*. His *History of Spain till the time of Charles V.*, said by Rioja to have been completed about 1590, has not come down to our time.

³ The very wonderful Shoe-bird (*Balwiniceps*) has been regarded by many authorities as allied to *Cancroma*, but there can be little doubt that it is more nearly related to the genus *Scopus* belonging to the Storks. The Sun-Bittern (*Eurypyga*), by some systematists considered to belong to the *Ardeidae*, would appear to have greater affinity to the *Rallidae*, if it does not form a Family of itself.

HERRERA, FRANCISCO (1576–1656), surnamed el Viejo (the old), historical and fresco painter, studied under Luis Fernandez in Seville, his native city, where he spent the most of his life. Although so rough and coarse in manners that neither scholar nor child could remain with him, the great talents of Herrera, and the promptitude with which he used them, brought him abundant commissions. He was also a skilful worker in bronze, an accomplishment that led to his being charged with coining base money. From this accusation, whether true or false, he sought sanctuary in the Jesuit college of San Hermenegildo, which he adorned with a fine picture of its patron saint. Philip IV., on his visit to Seville in 1624, having seen this picture, and learned the position of the artist, pardoned him at once, warning him, however, that such powers as his should not be degraded. In 1650 Herrera removed to Madrid, where he lived in great honour till his death in 1656. Herrera was the first to relinquish the timid manner of the old Spanish school of painting, and to initiate the free, vigorous touch and style which reached such perfection in Velazquez, who had been for a short time his pupil. His pictures are marked by an energy of design and freedom of execution quite in keeping with his bold, rough character. He is said to have used very long brushes in his painting; and it is also said that, when pupils failed, his servant used to dash the colours on the canvas with a broom under his directions, and that he worked them up into his designs before they dried. The drawing in his pictures is correct, and the colouring original and skilfully managed, so that the figures stand out in striking relief. What has been considered his best easel-work, the Last Judgment, in the church of San Bernardo at Seville, is an original and striking composition, showing in its treatment of the nude how ill-founded the common belief was that Spanish painters, through ignorance of anatomy, understood only the draped figure. Perhaps his best fresco is that on the dome of the church of San Buenaventura; but many of his frescos have perished, some by the effects of the weather, and others by the artist's own carelessness in preparing his surfaces. He has, however, preserved several of his own designs in etchings. For his easel-works Herrera often chose such humble subjects as fairs, carnivals, ale-houses, and the like.

See Stirling's *Annals of the Artists of Spain*, 3 vols., 1848.

HERRERA, FRANCISCO (1622–1685), surnamed el Mozo (the young), historical and fresco painter, son of the subject of last notice, was also a native of Seville. Unable to endure his father's cruelty, the younger Herrera, seizing what money he could find, fled to Rome. There, instead of devoting himself to the antiquities and the works of the old Italian masters, he gave himself up to the study of architecture and perspective, with the view of becoming a fresco-painter. He did not altogether neglect easel-work, but became renowned for his pictures of still-life, flowers, and fruit, and from his skill in painting fish was called by the Italians *Lo Spagnuolo degli pesci*. In later life he painted portraits with great success. He returned to Seville on hearing of his father's death; and in 1660 was appointed subdirector of the new academy there under Murillo. His vanity, however, brooked the superiority of no one; and throwing up his appointment he went to Madrid. There he was employed to paint a San Hermenegildo for the barefooted Carmelites, and to decorate in fresco the roof of the choir of San Felipe el Real. The success of this last work procured for him a commission from Philip IV. to paint in fresco the roof of the Atocha church. He chose as his subject for this the Assumption of the Virgin. Soon afterwards he was rewarded with the title of painter to the king, and was appointed superintendent of the royal buildings. He died at Madrid in 1685. Herrera el Mozo was of a somewhat similar temperament to his father, and

offended many people by his inordinate vanity and suspicious jealousy. His pictures are inferior to the older Herrera's both in design and in execution; but in some of them traces of the vigour of his father, who was his first teacher, are visible. He was by no means an unskilful colourist, and was especially master of the effects of chiaroscuro. As his best picture Sir Edmund Head in his *Handbook* names his San Francisco, in Seville Cathedral. An elder brother, known as Herrera el Rubio (the ruddy), who died very young, gave great promise as a painter.

See Stirling's *Annals of the Artists of Spain*, 3 vols., 1848.

HERRERA Y TORDESILLAS, ANTONIO DE (1549–1625), Spanish historian, was born in 1549, at Cuellar, in the province of Segovia in Spain. His father, Roderigo de Tordesillas, and his mother, Agnes de Herrera, were both of good family. After studying for some time in his native country, Herrera proceeded to Italy, and there became secretary to Vespasian Gonzago, with whom, on his appointment as viceroy of Navarre, he returned to Spain. Gonzago, sensible of his secretary's abilities, commended him on his death-bed to Philip II. of Spain; and that monarch, no less discerning, appointed Herrera first historiographer of the Indies, and one of the historiographers of Castile. Placed thus in the enjoyment of an ample salary, Herrera devoted the rest of his life to the peaceful pursuit of literature, retaining his offices till the reign of Philip IV., by whom he was appointed secretary of state, very shortly, however, before his death, which took place at Madrid on March 29, 1625. Of Herrera's writings, the most valuable is his *Historia General de los Hechos de los Castellanos en las Islas y Tierra Firme del Mar Oceano* (Madrid, 1601–15, 4 vols. fol.), a work which relates the history of the Spanish-American colonies from 1492 to 1554. The author's official position gave him access to the state papers and to other authentic sources not attainable by other writers, while he did not scruple to borrow largely from other MSS., especially from that of Las Casas. He used his facilities carefully and judiciously; and the result is a work on the whole accurate and unprejudiced, and quite indispensable to the student either of the history of the early colonies, or of the institutions and customs of the aboriginal American peoples. Although it is written in the form of annals, mistakes are not wanting, and several glaring anachronisms have been pointed out by Quintana. "If," to quote Dr Robertson, "by attempting to relate the various occurrences in the New World in a strict chronological order, the arrangement of events in his work had not been rendered so perplexed, disconnected, and obscure that it is an unpleasant task to collect from different parts of his book and piece together the detached shreds of a story, he might justly have been ranked among the most eminent historians of his country."

Herrera's other works are the following:—*Historia de lo Sucedido en Escocia é Inglaterra en quarante y quatro años que vivió la reyna Maria Estuarda* (Madrid, 1589); *Cinco Libros de la Historia de Portugal, y Conquista de las Islas de los Açores, 1582 y 1583* (ib., 1591); *Historia de lo Sucedido en Francia, 1585–1594* (ib., 1598); *Historia General del Mundo del tiempo del Señor Rey Don Felipe II., desde 1559 hasta su muerte* (ib., 1601–12, 3 vols. fol.); *Tratado, Relacion, y Discurso historico de los movimientos de Aragon* (ib., 1612); *Comentarios de los Hechos de los Españoles, Franceses, y Venecianos en Italia, &c., desde 1281 hasta 1559* (ib., 1624, fol.).

HERRICK, ROBERT (1591–1674), English poet, was born in Cheapside, London, and baptized on the 24th of August 1591. He was the seventh child of Nicholas Herrick, goldsmith, of the city of London, who died in 1592, under suspicion of suicide. The children were brought up by their uncle, Sir William Herrick, one of the richest goldsmiths of the day, to whom in 1607 Robert was bound apprentice. In 1613 he proceeded to Cambridge; and it was no doubt between these dates that the young poet was introduced to that circle of wits which he

was afterwards to adorn He seems to have been present at the first performance of *The Alchemist* in 1610, and it was probably about this time that Ben Jonson adopted him as his poetical "son." He entered the university as fellow-commoner of St John's College, and he remained there until, in 1616, upon taking his degree, he removed to Trinity Hall; in 1620 he became master of arts. From this date until 1629 we entirely lose sight of him; it has been variously conjectured that he spent these nine years preparing for the ministry at Cambridge, or in much looser pursuits in London. In the latter year his mother died, and, taking orders, he was presented to the rural living of Dean Prior, not far from Totnes in Devonshire. He entered upon this new career on October 2, 1629, being in his thirtieth year. At Dean Prior he resided quietly until 1648, when he was ejected by the Puritans. The solitude there oppressed him at first; the village was dull and remote, and he felt very bitterly that he was cut off from all literary and social associations; but soon the quiet existence in Devonshire soothed and delighted him. He was pleased with the rural and semi-pagan customs that survived in the village, and in some of his most charming verses he has immortalized the morris-dances, wakes, and quintains, the Christmas mummers and the Twelfth Night revellings, that diversified the quiet of Dean Prior. Herrick never married, but lived at the vicarage surrounded by a happy family of pets, and tended by an excellent old servant named Prudence Baldwin. His first appearance in print was in some verses he contributed to *A Description of the King and Queen of Fairies*, in 1635. In 1640 a volume of *Wit's Recreations* contained sixty-two small poems afterwards acknowledged by Herrick in the *Hesperides*, and one not reprinted until our own day. These partial appearances make it probable that he visited London from time to time. We have few hints of his life as a clergyman. Anthony Wood says that Herrick's sermons were florid and witty, and that he was "beloved by the neighbouring gentry." A very aged woman, one Dorothy King, stated that the poet once threw his sermon at his congregation, cursing them for their inattention. The same old woman recollected his favourite pig, which he taught to drink out of a tankard. In 1648 he published his celebrated collection of lyrical poems, entitled *Hesperides, or the Works both Human and Divine of Robert Herrick*, only a few weeks, it would seem, after his ejection from his living by the Puritans. That he was reduced to great poverty in London has been stated, but Dr Grosart shows this to be very unlikely. In August 1662 Herrick returned to Dean Prior, supplanting his own supplanter, Dr John Syme. He died in his eighty-fourth year, and was buried at Dean Prior, October 15, 1674. A monument was erected to his memory in the parish church in 1857.

As a pastoral lyricist Herrick stands first among English poets. His genius is limited in scope, and comparatively unambitious, but in its own field it is unrivalled. His tiny poems—and of the thirteen hundred that he has left behind him not one is long—are like jewels of various value, heaped together in a casket. Some are of the purest water, radiant with light and colour, some were originally set in false metal that has tarnished, some were rude and repulsive from the first. Out of the unarranged, heterogeneous mass the student has to select what is not worth reading, but, after he has cast aside all the rubbish, he is astonished at the amount of excellent and exquisite work that remains. Herrick has himself summed up, very correctly, the themes of his sylvan muse when he says:—

I sing of brooks, of blossoms, birds and bowers,
Of April, May, of June and July flowers,
I sing of May-poles, hock-carts, wassails, wakes,
Of bridegrooms, brides, and of their bridal-cakes.

He saw the picturesqueness of English homely life as no one before him had seen it, and he described it in his verse with a certain purple glow of Arcadian romance over it, in tones of immortal vigour and freshness. His love poems are still more beautiful; the best of them have an ardour and tender sweetness which give them a place in the forefront of modern lyrical poetry, and remind us of what was best in Horace and in the poets of the Greek anthology.

After suffering complete extinction for more than a century, the fame of Herrick was revived by Mr Nichols (Sylvanus Urban), who introduced his poems to the readers of the *Gentleman's Magazine* of 1796 and 1797. Dr Drake followed in 1798 with considerable enthusiasm. By 1810 interest had so far revived in the forgotten poet that Dr Nott ventured to print a selection from his poems, which attracted the favourable notice of the *Quarterly Review*. In 1823 the *Hesperides* and the *Noble Numbers* were for the first time edited by Mr T. Maitland, afterwards Lord Dundrennan. Other editions followed in 1839, 1844, 1846, 1850, 1852, and 1859. A more complete collection, by Mr W. C. Hazlitt, was brought out in 1869. In 1876 followed Dr Grosart's exhaustive and authoritative edition in three vols., and in 1877, under the title of *Chrysolata*, a very elegant selection by Mr F. T. Palgrave, with a prefatory essay. There are therefore few English poets of the 17th century whose writings are now more accessible to every class of readers than those of Herrick.

HERRING (*Clupea harengus*, Häring in German, *Le Hareng* in French, *Sill* in Swedish), a fish belonging to the genus *Clupea*, of which more than sixty different species are known in various parts of the globe. The sprat, pilchard or sardine, and shad are species of the same genus. Of all sea-fishes *Clupeæ* are the most abundant; for although other genera may comprise a greater variety of species, they are far surpassed by *Clupea* with regard to the number of individuals. The majority of the species of *Clupea* are of greater or less utility to man; it is only a few tropical species that acquire, probably from their food, highly poisonous properties, so as to be dangerous to persons eating them. But no other species equals the Common Herring in importance as an article of food or commerce. It inhabits in incredible numbers the German Ocean, the northern parts of the Atlantic, and the seas north of Asia. The herring inhabiting the corresponding latitudes of the North Pacific is another species, but most closely allied to that of the eastern hemisphere. Formerly it was the general belief that the herring inhabits the open ocean close to the Arctic Circle, and that it migrates at certain seasons towards the northern coasts of Europe and America. This view has been proved to be erroneous, and we know now that this fish lives throughout the year in the vicinity of our shores, but at a greater depth, and at a greater distance from the coast, than at the time when it approaches land for the purpose of spawning.

Herrings are readily recognized and distinguished from the other species of *Clupea* by having an ovate patch of very small teeth on the vomer (that is, the centre of the palate). In the dorsal fin they have from 17 to 20 rays, and in the anal fin from 16 to 18; there are from 53 to 59 scales in the lateral line, and invariably 56 vertebrae in the vertebral column. They have a smooth gill-cover, without those radiating ridges of bone which are so conspicuous in the pilchard and other *Clupeæ*. The sprat cannot be confounded with the herring, as it has no teeth on the vomer, and only 47 or 48 scales in the lateral line.

Herrings grow very rapidly; according to H. A. Meyer's observations, they attain a length of from 17 to 18 mm. during the first month after hatching, 34 to 36 mm. during the second, 45 to 50 mm. during the third, 55 to 61 mm. during the fourth, and 65 to 72 mm. during the fifth. The size which they finally attain and their general condition depend chiefly on the abundance of food (which consists of crustaceans and other small marine animals), on the temperature of the water, on the season at which they have been hatched, &c. Their usual size is

about 12 inches, but in some particularly suitable localities they grow to a length of 15 inches, and instances of specimens measuring 17 inches are on record. In the Baltic, where the water is gradually losing its saline constituents, thus becoming less adapted for the development of marine species, the herring continues to exist in large numbers, but as a dwarfed form, not growing either to the size or to the condition of the North-Sea herring. The herring of the American side of the Atlantic is specifically identical with that of Europe. A second species (*Clupea leachii*) has been supposed to exist on the British coast; but it comprises only individuals of a smaller size, the produce of an early or late spawn. Also the so-called "white-bait" is not a distinct species, but consists chiefly of the fry or the young of herrings, and is obtained "in perfection" at localities where these small fishes find an abundance of food, as in the estuary of the Thames. The important subject of herring-fishing has already been treated in the article FISHERIES (see vol. ix. pp. 251, 257, &c.).

Several excellent accounts of the herring have been published, as by Valenciennes in the 20th vol. of the *Histoire naturelle des Poissons*, and more especially by Mr J. M. Mitchell, *The Herring, its Natural History and National Importance*, Edin., 1864. Older treatises are—P. Neucrantz, *De Harengo*, Lübeck, 1654; J. S. Dodd, *Essay towards a Natural History of the Herring*, Lond., 1763; J. Sola, *Essay towards a Natural History of Herrings*; Bock, *Versuch einer vollständigen Natur- und Handels-Geschichte der Härrings*, Königsberg, 1769.

HERRNHUT, a town of Saxony, in the circle and 18 miles south-east of the town of Bautzen, and situated on the Löbau and Zittau Railway, is chiefly known as the principal seat of the Moravian or Bohemian Brotherhood, styled on the Continent Herrnhuter, a colony of whom, fleeing from persecution in their own country, settled at Herrnhut in 1722, on a site presented by Count Zinzendorf. The buildings include houses for the brethren, the sisters, and the widowed of both sexes. The town is remarkable for its regularity, cleanness, and stillness. Linen, paper (to varieties of which Herrnhut gives its name), tobacco, and various minor articles are manufactured. The Hutberg commands a pleasant view. The population in 1875 was 1128. Berthelsdorf, a village about a mile distant, has been the seat of the directorate of the community since about 1789.

HERSCHEL, CAROLINE LUCRETIA (1750–1848), sister of Sir William Herschel, the eighth child and fifth daughter of her parents, was born at Hanover on the 16th March 1750. On account of the prejudices of her mother, who did not desire her to know more than was necessary for being useful in the family, she received in youth only the first elements of education. After the death of her father in 1767 she, in order to fit herself to earn her bread, obtained permission to learn millinery and dressmaking, but continued to assist her mother in the management of the household until the autumn of 1772, when she accompanied to England her brother William, who had established himself as a teacher of music in Bath. At once she became a valuable co-operator with her brother, both in his professional duties and in the astronomical researches to which he had already begun to devote all his spare time. She was the principal singer at his oratorio concerts, and acquired such a reputation as a vocalist that she was offered an engagement for the Birmingham festival, which, however, she declined. When her brother accepted the office of astronomer-royal, she became his constant assistant in his observations, and also executed the laborious calculations which were connected with them. For these services she in 1787 received from the king a salary of £50 a year. Her chief amusement during her leisure hours was to sweep the heavens with a small Newtonian telescope planted on the lawn. Besides detecting by this means many of the small nebulae included in Sir William Herschel's catalogue,

she succeeded in discovering seven comets, in the discovery of five of which she could lay claim to priority, viz., those of 1786, 1788, 1791, 1793, and 1795. In 1797 she presented to the Royal Society a catalogue of 560 stars taken from Flamsteed's observations, and not included in the British catalogue, together with a collection of errata that should be noticed in the same volume. Though she returned to Hanover in 1822 she did not abandon her astronomical studies, and in 1828 she completed the reduction, to January 1800, of 2500 nebulae discovered by her brother. In 1835 the Astronomical Society, to mark their sense of the benefits conferred on science by such a series of laborious exertions, unanimously resolved to present her with their gold medal, and also elected her an honorary member of the society. In 1846 she received a gold medal from the king of Prussia. She retained the use of her intellectual faculties, and also preserved her interest in science, to the close of a long life. Her death took place on 9th January, 1848. *The Memoir and Correspondence of Caroline Herschel*, by Mrs John Herschel, appeared at London in 1876.

HERSCHEL, SIR FREDERICK WILLIAM (1738–1822), generally known as Sir William Herschel, one of the most illustrious of astronomers, was born at Hanover, November 15, 1738. His father was a musician employed as hautboy player in the Hanoverian guards. The family had migrated from Bohemia in the early part of the 17th century, on account of religious troubles, they themselves being Protestants. Herschel's earlier education was necessarily of a very limited character, chiefly owing to the troubles in which his country at that time was involved; but, being at all times an indomitable student, he, by his own exertions, more than repaired this deficiency of his youth. He became a very skilful musician, both theoretical and practical; while his attainments as a self-taught mathematician were fully adequate to the prosecution of those branches of astronomy which, by his labours and his genius, he so eminently advanced and adorned. Whatever he did he did methodically and thoroughly; and in this methodical thoroughness lay the secret of what Arago very properly terms his astonishing scientific success.

In 1755, at the age of seventeen, he joined the band of the Hanoverian guards, and with his detachment visited England, accompanied by his father and eldest brother; in the following year he returned to his native country, but two years later, impelled by the troubles that surrounded him, he finally quitted Hanover to seek his fortunes in England. As might have been expected, the earlier part of his career in his adopted country was attended with formidable difficulties and much privation. We find him engaged in several towns in the north of England as organist and teacher of music, but these were occupations not attended with any lucrative results. In 1766 the tide of his fortunes began to flow, inasmuch as he obtained the appointment of organist to the Octagon Chapel in Bath, at that time the resort of the wealth and fashion of the city, and of its numerous distinguished visitors.

The next five or six years of his life were spent in establishing his reputation as a musician, and he thereby eventually became the leading musical authority in the place, and the director of all the chief public musical entertainments. His circumstances having thus become easier, he revisited Hanover for the purpose of bringing back with him his sister Caroline, with the view of her rendering him such services as she could in his multifarious undertakings. She arrived in Bath with her brother in August 1772, being at that time in her twenty-third year. She thus describes her brother's life soon after her arrival:—"He used to retire to bed with a bason of milk or a glass of water, with Smith's *Harmonics* and Ferguson's

Astronomy, &c., and so went to sleep buried under his favourite authors; and his first thoughts on waking were how to obtain instruments for viewing those objects himself of which he had been reading." It is not without significance that we find him thus reading Smith's *Harmonics*; to that study loyalty to his profession would impel him; as a reward for his thoroughness this led him to Smith's *Optics*; and this, by a natural sequence, again led him to astronomy, for the purposes of which the chief optical instruments were devised. It was in this way that he was introduced to the writings of Ferguson and Keill, and subsequently to those of Lalande, whereby he was educating himself for an astronomer and for undying fame. In those days telescopes were very rare, very expensive, and not very efficient, for the Dollonds had not as yet perfected even their beautiful little achromatics of $2\frac{3}{4}$ inches aperture. So Herschel was obliged to content himself with hiring a small Gregorian reflector of about 2 inches aperture, which he had seen exposed for loan in a tradesman's shop. Not satisfied with this implement, he procured a small lens of about 18 feet focal length, and set his sister to work on a pasteboard tube of that length, so as to make him a telescope. A tube of this construction naturally bent, and it was useless for all purposes but for the determined eyes of William Herschel. This material was soon displaced for tin, and thus a sorry sort of vision was obtained of Jupiter and Saturn and the moon. He then sought for a reflector of much larger dimensions from artists in London. No such instrument, however, was for sale; and the terms demanded for the construction of a reflecting telescope of 5 or 6 feet focal length he regarded as too exorbitant even for the gratification of such desires as his own. So he was driven to the only alternative that remained; he must construct a large telescope for himself. His first step in this direction was to purchase the debris of an amateur's implements for grinding and polishing small mirrors; and thus, by slow degrees, and by indomitable perseverance, he in 1774 had, as he says, the satisfaction of viewing the heavens with a Newtonian telescope of 6 feet focal length constructed by his own hands. But he was not a man to be contented with viewing the heavens as a mere star-gazer; on the contrary, he had from the very first conceived the gigantic project and the hope of surveying the entire heavens, and, if possible, of ascertaining the plan of their general structure on a settled and systematic mode of procedure, if only he could but provide himself with adequate instrumental means. With this view he, his brother, and his sister toiled for many years at the grinding and polishing of hundreds of specula, always retaining the best, and recasting the others, until the best of the previous performances had been surpassed. This was the work of the daylight in those seasons of the year when the fashionable visitors of Bath had quitted the place, and had thus freed the family from professional duties. After 1774 every available hour of the night was devoted to the long-hoped-for scrutiny of the skies. In those days no machinery had been invented for the construction of telescopic mirrors; the man who had the hardihood to undertake the polishing doomed himself to walk leisurely and uniformly round an upright post for many hours, without removing his hands from the mirror, until his work was done. On these occasions Herschel received his food from the hands of his faithful sister. But his reward was nigh.

In May 1780 his first two papers containing some of the results of his astronomical observations during the last six years were communicated to the Royal Society through the influential introduction of Dr Watson. Herschel had made the acquaintance of this excellent man and skilful physician in a characteristic manner. In order to obtain a sight of the moon the astronomer had taken his telescope

into the street opposite his house; the physician happening to pass at the time, and seeing his eye removed for a moment from the instrument, requested permission to take his place. The mutual courtesies and intelligent conversation which ensued soon ripened this casual acquaintance into a solid and enduring regard.

The subject of this first memoir was the varying lustre of several of the stars, and especially that of Mira in the constellation of Cetus. It had been long known to fade in brightness from nearly that of a star of the first magnitude down to invisibility in such telescopes as then existed. Herschel had examined it, and many other variable stars, for himself; it was not, however, a simple or isolated phenomenon that engaged his attention; but, regarding the stars as so many suns, he examined stellar phenomena as possibly leading him to some intelligent conception of what might be occurring in our own sun. The sun, he knew, rotated on its axis, and he knew that dark spots often exist on its photosphere; the questions that he put to himself were—Are there dark spots also on these variable stars? do the stars also rotate on their axes? or are they sometimes partially eclipsed by the intervention of some opaque and invisible bodies? And then he asked himself—What are these singular spots upon the sun? and have they any practical relation to us, the inhabitants of this planet? To these questions he applied his telescopes and his thoughts; and as light from time to time dawned upon his apprehension, he communicated the results to the Royal Society in no less than six memoirs, occupying very many pages in the *Philosophical Transactions*, and extending in date from 1780 to 1801. It was in the latter year that these remarkable papers culminated in the inquiry whether any relation could be traced in the recurrence of sun-spots, regarded as evidences of solar activity (allied to volcanic), and the varying seasons of our planet, as exhibited by the varying price of corn? Herschel's solution of the question was scarcely final, and the question has recently cropped up again, with more than a renewal of its former interest.

In the following year (1781) he communicated to the Royal Society the first of a series of papers containing the results of his telescopic inquiries in relation to the rotation of the planets and of their several satellites. The object which he had in view was not so much to ascertain the velocities or times of their rotation, as rather to discover whether those rotations are strictly uniform. From the result he expected to gather, by analogy, the probability of an alteration in the length of our own day. These inquiries occupy the greater part of seven memoirs extending from 1781 to 1797. In the course of these telescopic observations he lighted on the curious appearance of a white spot near to each of the poles of the planet Mars. On investigating the inclination of its axis to the plane of its orbit, and finding that it closely resembled that of our earth, he concluded that its changes of climate also would resemble our own, and that these white patches were probably polar snow. Modern investigations have confirmed his conclusion. He also discovered that, as far as his observations extended, the times of the rotations of the various satellites round their axes are in analogy with our own moon, viz., equal to the times of their revolution round their primaries. Here again we observe that his discoveries arise out of the complete and systematic and comprehensive nature of the investigation in which he is engaged. Nothing with such a man is accidental.

In the same year (1781) Herschel made a discovery which, as we shall see, soon completely altered the character of his professional life. In the course of his systematic examination of the heavens with a view to the discovery of the plan of their construction, he lighted on an object which at first he supposed to be a comet, but which, by its subse-

quent motions and appearance, turned out to be a new planet, moving outside of the orbit of Saturn. To this planet he in due time assigned the name of Georgium Sidus; but this name has by general consent been laid aside in favour of Uranus. It was discovered with a favourite 7-foot reflector having an aperture of $6\frac{1}{2}$ inches; subsequently, when he had provided himself with a much more powerful telescope, of 20 feet focal length, he discovered what he believed to be no less than six satellites. Modern observations have shorn this gloomy planet of four of these supposed attendants, but at the same time have added two others apparently not observed by Herschel. No less than seven memoirs on the subject were communicated by him to the Royal Society, extending from the date of the discovery in 1781 to 1815. There is a peculiarity worthy of notice in Herschel's mode of observation which led to the discovery of this planet. He had observed that the spurious diameters of stars are not much affected by increasing the magnifying powers, but that the case is different with other celestial objects; hence if anything in his telescopic field attracted his notice by peculiarity of appearance, he immediately varied the magnifying power in order to decide the nature of the object. Thus Uranus was discovered; and had a similar method been applied to Neptune, that planet would have been discovered at Cambridge some months before it was recognized at Berlin.

We now come to the commencement of Herschel's most important series of observations, culminating in what ought probably to be regarded as his most capital discovery. A material part of the task which he had set himself as the work of his astronomical life embraced the determination of the relative distances of the stars from our sun and from each other. Now, in the course of his scrutiny of the heavens, he had observed many stars in apparently very close contiguity, but often greatly differing in their relative brightness. He concluded that, on the average, the brighter star would be the nearer to us, and the smaller enormously more distant. He considered that an astronomer on the earth, in consequence of its immense orbital displacement of some 180 millions of miles every six months, would see such a pair of stars under different perspective aspects; and this variety of perspective aspect observed and measured would, he thought, lead to an approximate determination of their distance. With this view he mapped down the places and aspects of all the double stars that he met with, and communicated in 1782 and 1785 very extensive catalogues of the results. Indeed, the very last scientific memoir that he ever wrote, sent to the Royal Astronomical Society in the year 1822, at the time when he was its first president and already in the eighty-fourth year of his age, related to these investigations. In the first of these memoirs he throws out the hint that these apparently contiguous stars must, if constituted after the material laws of our solar system, circulate round each other through the effects of gravitation; but he significantly adds that the time had not yet arrived for settling the question. Thus the philosopher abides his time in patience and confidence, and a dozen years afterwards (1793) he remeasures the relative positions of many of these contiguous pairs, and we may conceive what his feelings must have been at finding the verification of his prediction. For he found that some of these stars had circulated round each other, after the manner required by the laws of gravitation. Thus Herschel had demonstrated the action of the same mechanical laws among the distant members of the starry firmament which bind together the harmonious motions of our solar system. This sublime discovery would of itself suffice to immortalize his memory in the respectful homage of all future races of intelligent men. If only

Herschel had lived long enough to learn the approximate distances of some of these binary combinations, he would at once have been able to calculate their masses when compared with that of our own sun; and thus, knowing, as we now do, that these stars in their weights are strictly comparable with the weight of our own sun, he would have found another of his analogical conjectures realized.

In the year 1782, in consequence of his fame, Herschel was invited to Windsor by George III., and then accepted the offer made by the king to become his private astronomer, and henceforth devote himself wholly to a scientific career. The salary offered and accepted was £200 per annum, to which an addition of £50 per annum was subsequently made for the astronomical assistance of his faithful sister. Dr Watson, to whom alone the amount of this salary was mentioned, made the natural remark, "Never before was honour purchased by a monarch at so cheap a rate." In this way the great philosophical astronomer removed from Bath first to Datchet and soon afterwards permanently to Slough, within the easy access of his royal patron at Windsor.

The old pursuits at Bath were soon resumed at Slough, but with renewed vigour and without the old professional interruptions. The greater part, in fact, of the papers already referred to are dated from Datchet and Slough, for the magnificent astronomical speculations in which he was engaged, though for the most part conceived in the earlier portion of his philosophical career, required years of patient observation before they could be fully examined and realized.

It was at Slough in 1783 that he wrote his first memorable paper on the "Motion of the Solar System in Space,"—a sublime speculation, yet through his genius realized by considerations of the utmost simplicity. He returned to the same subject with fuller details in 1805. It was also after his removal to Slough that he published his first memoir containing his speculative ideas on the construction of the heavens, which from the first had been the chief aim of his toils both of mind and body. In a long series of remarkable papers, addressed as usual to the Royal Society, and extending from the year 1784 to 1818, when he was eighty years of age, he demonstrated the fact that our sun is a star situated not far from the bifurcation of the Milky Way, and that all the stars visible to us lie more or less in clusters scattered throughout a comparatively thin stratum, but in the other two dimensions stretching immeasurably further into space. At one time he imagined that his powerful instruments had pierced through this stellar stratum of the Milky Way, and that he had approximately determined the form of some of its boundaries. In the last of his memoirs he had convinced himself of his error, and he admitted that to his telescopes our stratum of stars is "fathomless." Over this stratum of stars and their planetary attendants, the whole being in ceaseless motion round some common centre of gravity as the resultant point of the combined gravitation, Herschel discovered on either side a canopy of discrete nebulous masses, from the condensation of at least a part of which the whole stellar universe had been formed,—a magnificent conception, pursued with a force of genius and put to the practical test of observation with an industry almost incredible. It was the work of a single mind, carried to its termination with no assistance beyond that of a loyal sister, almost as remarkable a personage as himself.

Hitherto we have said nothing about that grand reflecting telescope, of 40 feet focal length and 4 feet aperture, which is too often regarded as the chief effort of his genius and his perseverance. The full description of this celebrated instrument will be found in the 85th volume of the *Transactions* of the Royal Society. Gigantic as it really

was, we are disposed to regard it as among the least of his great works. On the day that it was finished (August 28, 1789) Herschel saw at the first view, in a grandeur not witnessed before, the Saturnian system with all its six satellites, five of which had been discovered long before by Huygens or Cassini, while the sixth, latterly named Enceladus, he had, two years before, sighted by glimpses in his exquisite little telescope of $6\frac{1}{2}$ inches aperture, but now saw in unmistakable brightness with the towering giant he had just completed. On the 17th of September he discovered a seventh, which proved to be the nearest of all the satellites of Saturn. It has since that time received the name of Mimas. It is somewhat remarkable that, notwithstanding his long and repeated scrutinies of this planet, the eighth satellite, Hyperion, and the crape ring should have escaped him.

Herschel married the widow of Mr John Pitt, a wealthy London-merchant, on May 8, 1788, by whom he had an only son, John Frederick William. The prince regent conferred a Hanoverian knighthood upon him in 1816. But a far more valued and less tardy distinction was the Copley medal assigned to him by his associates in the Royal Society in 1781.

He died at Slough on August 25, 1822, in the eighty-fourth year of his age, and was buried under the tower of St Laurence Church, Upton, within a few hundred yards of the old site of the 40-foot telescope. A mural tablet on the wall of the church bears a Latin inscription from the pen of the late Dr Goodall, provost of Eton College. A collected edition of his astronomical memoirs would speak of his genius in unmistakable language; but this has not yet been published. (C. P.)

HERSCHEL, SIR JOHN FREDERICK WILLIAM, BART. (1792-1871), the illustrious astronomer, the only son of Sir F. William Herschel, was born at Slough, Bucks, in the year 1792. His early home was a singular one, and eminently adapted to nurture into greatness any child born, as he was, with natural gifts capable of wide development. The examples about him were those of silent but ceaseless industry, busied about things which, at the first view, seemed to have no apparent connexion with the world outside the walls of his abode, but which, at a mature period of his life, he, with rare eloquence, taught his countrymen to appreciate as foremost among those influences which satisfy and exalt the nobler instincts of our nature.

His scholastic education commenced at Eton, but maternal fears or prejudices soon removed him to the house of a private tutor. Thence, at the early age of seventeen, he was sent to St John's College, Cambridge, and the form and method of the mathematical instruction he there received exercised a material influence on the whole complexion of his scientific career. In due time the young student acquired the highest academical distinction of his year, graduating as senior wrangler. It was during his undergraduateship that he and two of his fellow-students who subsequently attained to very high eminence in their respective careers of life, Dean Peacock and Mr Babbage, entered into a sort of moral compact that they would "do their best to leave the world wiser than they found it,"—a compact loyally and successfully carried out by all three to the end. As a commencement of this laudable attempt we find Herschel associated with these two friends in the production of a work on the differential calculus, and on cognate branches of mathematical science, which changed the whole style and aspect of mathematical learning in England, and brought it up to the level of the Continental methods. Two or three memoirs communicated to the Royal Society on new applications of mathematical analysis at once placed him in the front rank of the cultivators of

this branch of knowledge. Of these his father had the gratification of introducing the first, but the others were presented in his own right as a fellow.

His first intention had been to study for the bar, and with this view he left the university, and placed himself under the guidance of an eminent special pleader of that day. Probably this temporary choice of a profession arose from the extraordinary success which for some time had attended the efforts of so many eminent Cambridge mathematicians in legal pursuits. Be that as it may, an early acquaintance with Dr Wollaston in London soon changed the direction of his studies. In 1820, assisted by his father, he completed a mirror of 18 inches diameter and 20 feet focal length, for a reflecting telescope. This, subsequently improved by his own hands, became the instrument which enabled him to effect the astronomical observations which, more than any other of his great works, form the basis of his fame. In 1821-23 we find him associated with Mr South in the re-examination of his father's double stars, by the aid of an achromatic telescope and other appliances, the like of which for excellence and power had not hitherto been collected. For this work in 1826 he received the recognition of the Astronomical Society by the award of their gold medal; the French Institute also presented him with the Lalande medal for the same contribution to astronomical science. It ought also to be mentioned that in 1821 the Royal Society had presented him with the Copley medal for his mathematical contributions to their *Transactions*. From 1824 to 1827 he held the distinguished and responsible post of secretary to that society. In 1827 he was elected to the chair of the Astronomical Society, which office he also filled on two subsequent occasions. In the course of the discharge of his important offices in the last-named society he ennobled its literature by his memorable presidential addresses and obituary notices of deceased fellows, which, it is not too much to say, are, by their combination of eloquence and wisdom, the chief adornments of their printed memoirs. In 1831 the honour of knighthood was conferred on him by William IV., and two years later he again received the recognition of the Royal Society by the award of one of their medals for his memoir "On the Investigation of the Orbits of Revolving Double Stars." There is a significance in this award; the father had been the original discoverer of the extension of gravitation to the remotest boundaries of the visible universe, and the son had now put the crowning stone to this edifice of discovery by the invention of a graphical method whereby the eye could as it were see the two component stars of the binary system revolving before it, after the regularity of the Newtonian law.

Before the end of the year 1833, being then about forty years of age, Sir John Herschel had re-examined all his father's discoveries of double stars and nebulae, and had added many similar bodies to his own list; this alone constituted a gigantic work even for the lifetime of any astronomer in that day. For it should be remembered that the astronomer was not as yet provided with those curious and valuable automatic contrivances for observing and for recording observations which at present most materially abridge the labour and increase the accuracy of astronomical work such as that in which Sir John had been engaged. And he had no assistant. Equatorial clocks for turning the telescope, electrical chronographs for recording the times of the phenomena observed, were at that date unknown.

His scientific life now entered another and very characteristic phase. The bias of his mind, as he subsequently was wont to declare, was towards chemistry and the phenomena of light, rather than towards astronomy. Indeed, very shortly after taking his academical degree at Cambridge, he proposed himself as a candidate for the vacant

chair of chemistry in that university; but, as he said with some humour, the result of the election was that of the votes he had a glorious minority of one. In fact Herschel had become an astronomer from a sense of duty, just as his father had become one by fascination and fixed resolve; hence it was by filial loyalty to his father's memory that he was now impelled to undertake the completion of that work which at Slough had been so grandly commenced. William Herschel had explored the northern heavens; John Herschel determined to explore the heavens of the south, as well as re-explore the north. "I resolved," he said, "to attempt the completion of a survey of the whole surface of the heavens; and for this purpose to transport into the other hemisphere the same instrument which had been employed in this, so as to give a unity to the results of both portions of the survey, and to render them comparable with each other." In accordance with this resolution, he and his family embarked for the Cape on the 13th November 1833; they arrived in Table Bay on the 15th January 1834; and proceedings, he says, "were pushed forward with such effect that on the 22d of February I was enabled to gratify my curiosity by a view of κ Crucis, the nebula about η Argus, and some other remarkable objects in the 20-foot reflector, and on the night of the 4th of March to commence a regular course of sweeping."

To give an adequate description of the vast mass of labour completed during the next four busy years of his life at Feldhausen would require the transcription of a considerable portion of the *Cape Observations*, a volume which probably is not surpassed in varied interest or astronomical importance by any scientific work in existence; although it might perhaps be equalled by a judicious selection from Sir William's "Memoirs," now scattered in some thirty volumes of the *Philosophical Transactions*. It was published, at the sole expense of the late duke of Northumberland, but not till 1847, nine years after the author's return to England, for the very cogent reasons assigned by himself:—"The whole of the observations, as well as the entire work of reducing, arranging, and preparing them for the press, have been executed by myself." There are 164 pages of catalogues of southern nebulae and clusters of stars. There are then careful and elaborate drawings of the southern appearance of the great nebula in Orion, and of the region surrounding the remarkable star of Argo. The labour and the thought bestowed upon some of these objects are almost incredible, several months were well spent upon a minute spot in the heavens containing 1216 stars, but which an ordinary spangle, held at a distance of an arm's length, would eclipse. These catalogues and charts being completed, he proceeds to discuss their significance, which in the eyes of science possesses an absorbing interest. He confirms his father's hypothesis that these wonderful masses of glowing vapours are not irregularly scattered, and without apparent law, hither and thither in the visible heavens, but are collected in a sort of canopy, whose vertex is at the pole of that vast stratum of stars in which our solar system finds its position,—buried in it, as he supposes, at a depth not greater than that of the average distance from us of an eleventh magnitude star. Then follows his catalogue of the relative positions and magnitudes of the southern double stars. And he applies to one of them, γ Virginis, that beautiful graphical method invented by himself, whereby he determines the orbit of the two components round each other, and he had the satisfaction of witnessing with his own eyes the fulfilment of a prediction he had made some years before, viz., that the two stars would, in the course of their orbital movements, appear to close up into a single star, inseparable by any telescopic power. The double stars and their stately revolutions and lustrous colours dismissed, in the next chapter he proceeds to describe the observations which he had made on their varying and relative brightness. It has been already detailed how his father commenced his scientific career by similar observations on the varying magnitudes of many stars, and how his remarks culminated years afterwards in the question whether the variation of the lustre of our sun, by the presence or absence of sun spots, affected our harvests and the price of corn. The son carries his speculations backwards to a still more philosophical depth. The variation from time to time, he remarks, in the lustre of our sun, to the extent of half a magnitude, would account for those strange alternations of a semi-arctic and semi-tropical climate which geological researches have disclosed as having occurred in various regions of our globe.

Herschel returned to his English home in the spring of 1838. As was natural and honourable to all concerned, he was welcomed with an enthusiastic greeting. By the queen

at her coronation he was created a baronet; and, what to him was better than all such rewards, other men caught the contagion of his example, and laboured in fields similar to his own, with an adequate portion of his success. In particular Mr Lassell transported a telescope as large as the celebrated Herschelian telescope to Malta, where with excellent results he "minded the heavens" for the space of four years. He was rewarded there, and at his own English residence near Liverpool, by the discovery of new satellites of Saturn and of Uranus, constituting what Sir John Herschel, animated by a fraternal sympathy, well called an epoch in astronomy. Mr De La Rue also, at Islington and at Cranford, followed zealously and successfully in the wake of the same infectious enthusiasm.

Herschel was a highly accomplished chemist. His discovery of the solvent power of hyposulphite of soda on the otherwise insoluble salts of silver, in 1819, exercised a most important influence on the practical applications of photography twenty years afterwards; and in 1839, the natal era of that valuable art, he, independently of Mr Fox Talbot, had discovered the means of taking and multiplying photographic pictures, and early in the spring of that year exhibited more than twenty photographic pictures to the Royal Society, including one of the old 40-foot telescope. He was the first person to introduce the now well-known terms *positive* and *negative* in photographic images, and to deposit upon glass a sensitized film for the reception of the picture. He also paved the way for Professor Stokes's important discovery of the change which luminous waves may suffer in their period of oscillation, by his addition of the lavender rays to the spectrum, and by his announcement of "epipolic dispersion," as exhibited by sulphate of quinine. Several other important and successful researches of his, connected with the undulatory theory of light, are scattered through the pages of his treatise on "Light" published in the *Encyclopædia Metropolitana*.

To the other varied accomplishments of his gifted mind we must add the graces of a deep poetic feeling. Perhaps no man can become a truly great mathematician or great philosopher, if unendowed with the versatile powers of the imagination. John Herschel possessed this endowment to a large extent; and he had reserved for himself as a selace and enjoyment in old age the translation of the *Iliad* into verse. He had at an earlier period of life translated in a similar manner Schiller's *Walk*. But the main work of his declining years was the collection of all his father's catalogues, combined with his own observations and those of other astronomers of nebulae and double stars, each into a single volume. He lived to complete the former, and to present it to the Royal Society, who have published it in a separate form in the *Philosophical Transactions*. The latter work he had not fully completed at his death; but he bequeathed as much of it as was finished to the Astronomical Society. That society has printed a portion of it, which serves as an index to the observations of various astronomers on double stars up to the year 1866.

A complete list of his various contributions to learned societies will be found in the Royal Society's great catalogue, and from them may be gathered most of the records of his busy scientific life. Sir John Herschel met with an amount of public recognition which was unusual in the time of his illustrious father. Naturally he was a member of almost every important learned society in both hemispheres. For five years he held the office of master of the mint, the same appointment which, more than a century before, had been occupied by Sir Isaac Newton; his friends also offered to propose him as president of the Royal Society and again as a member of parliament for the university of Cambridge, but neither office was within the scope of his own desires.

In private life Sir John Herschel was a firm and most active friend; he had no jealousies; he avoided all scientific feuds; he gladly accorded a helping hand to those who consulted him in scientific difficulties; he never discouraged, and still less disparaged, men younger than or inferior to himself; he was pleased when his own work was appreciated, but that was never an object of his solicitude: it was said of him by a discriminating critic, and without extravagance, that "his was a life full of the serenity of the age and the docile innocence of a child."

He died at Collingwood, his residence near Hawkhurst in Kent, May 11, 1871, in the seventy-ninth year of his age, and his remains are interred in Westminster Abbey close to the grave of Sir Isaac Newton.

Sir John Herschel, independently of the labours connected with his *Cape Observations*, was the author of several books, one of which at least, *On the Study of Natural Philosophy* (1830), possesses an interest which no future advances of the subjects on which he wrote can obliterate from the attention of thoughtful men in any age. In 1849 came the *Outlines of Astronomy*, of which it is enough to say that, notwithstanding the obvious disadvantage arising from the practice of stereotyping text-books which relate to progressive sciences, there is no more instructive volume extant on the subject of which it treats. His articles, "Meteorology," "Physical Géography," and "Telescope," contributed to the 8th edition of the *Encyclopædia Britannica*, were afterwards published separately. There is also another very valuable little book, which originated from a happy peculiarity of Sir John Herschel's dignified simplicity and truthfulness of mind. When he was at the Cape he more than once assisted in the attempts there made to diffuse a love of knowledge among men not engaged in literary pursuits. In one of his addresses he, with a kindly and far-seeing wisdom, told his audience that the advance of a nation's intelligence or a nation's fame did not depend upon a few successful philosophers toiling in their lonely studies, and gathering great reputations for their learning or their discoveries, but that a nation's progress rather lay in the diffusion of their knowledge among the masses of the population. Acting practically on this principle, he, on his return to England, published, in *Good Words* and elsewhere, a series of papers on interesting points of natural philosophy, which have since been collected in a volume called *Familiar Lectures on Scientific Subjects*. None but a deep thinking philosopher could have written this book; none but a clear thinking master of his subjects could have made it what it is, enticingly intelligible. Another volume of his, not so widely known to the public as any of the above works, is his *Collected Addresses*, in which he is seen in his happiest and most instructive mood, walking, as it were, at liberty among sympathizing associates, in his own fields, and enamoured of their beauties. (C. P.)

HERSENT, LOUIS (1777-1860), French painter, was one of David's most distinguished pupils, and became one of the most noted painters of the Restoration. He was born at Paris on 10th March 1777, and obtained the Prix de Rome in 1797; in the Salon of 1802 appeared his *Metamorphosis of Narcissus*, and he continued to exhibit with rare interruptions up to 1831. His most considerable works under the empire were Achilles parting from Briseis, and Atala dying in the arms of Chactas (both engraved in Landon's *Annales du Musée*); an Incident of the life of Fénelon, painted in 1810, found a place at Malmaison, and Passage of the Bridge at Landshut, which belongs to the same date, is now at Versailles. Hersent's typical works, however, belong to the period of the Restoration; Louis XVI. relieving the Afflicted (Versailles) and Daphnis and Chloe (engraved by Langier and by Gelée) were both in the Salon of 1817; at that of 1819 the Abdication of Gustavus Vasa brought to Hersent a medal of honour, but the picture, purchased by the duke of Orleans, was destroyed at the Palais Royal in 1848, and the engraving by Henriquel-Dupont is now its sole record. Ruth, produced in 1822, became the property of Louis XVIII., who from the moment that Hersent rallied to the Restoration zealously patronized him, made him officer of the legion of honour, and pressed his claims at the Institute, where he replaced Van Spaendonck. He continued in favour under Charles X., for whom was executed Monks of Mount St Gotthard, exhibited in 1824: In 1831 Hersent made his

last appearance at the Salon with portraits of Louis Philippe, Marie-Amélie, and the duke of Montpensier; that of the king, though good, is not equal to the portrait of Spontini (Berlin), which is probably Hersent's *chef-d'œuvre*. After this date Hersent ceased to exhibit at the yearly salons. Although in 1846 he sent an excellent likeness of Delphine Gay and one or two other works to the rooms of the Société d'Artistes, he could not be tempted from his usual reserve even by the international contest of 1855. Five years later, on 2d October 1860, he died. His work shows every artistic merit which can be attained by steadily directed intelligence and labour; his skilful arrangement, delicacy of line, and certainty in execution are points which have excited the admiration even of those who find him wanting in feeling, in interest, and in sense of colour. Louis XVI. relieving the Afflicted, the treatment of which indicates the approach of the realistic movement, is less theatrical than Daphnis and Chloe, which combines, in the true spirit of the Restoration, drawing-room graces with a pseudo-classic style; but both show the same dryness and hardness of manner which Hersent had acquired under the influence of the first empire, and from which he never was able to free himself.

HERSFELD, a town of Prussia, capital of a circle in the government district of Cassel, province of Hesse-Nassau, is pleasantly situated at the confluence of the Geisa and Haune with the Fulda, on the railway from Frankfort to Bebra, 10 miles N.N.E. of Fulda. The greater part of its old fortifications remain, but the ramparts and ditches have been laid out as promenades. The principal buildings are the ancient town-house; the parish church, completed in 1320, in the Gothic style, with a fine tower and a large bell; the ruins of the collegiate church in the Byzantine style, erected in the beginning of the 12th century on the site of the cathedral, but burnt down by the French during the Seven Years' War; and outside the town the ancient monastery with its surrounding grounds. Among the public institutions are a gymnasium, a higher town school, an orphanage, and a district infirmary. The town has important manufactures of cloth and leather, as well as dye-works, worsted mills, and soap-boiling works. The population in 1875 was 6929.

Hersfeld owes its origin to a Benedictine abbey which, founded by Lullus, archbishop of Mainz, about 760, was richly endowed by Charlemagne, and became in the 12th century an ecclesiastical principality. In 1370 the town came under the protection of Hesse, and in 1525 it gave in its formal allegiance to it. The abbey was secularized in 1648, but Hersfeld remained the capital of a principality until 1828.

HERSTAL, or in its older form HERISTAL, a market-town of Belgium, on the left bank of the Meuse, 3 or 4 miles north-east of Liège, and skirting the road which leads from that city to Maastricht. Its population, which in 1876 numbered 11,126, is mainly supported by its coal mines and iron industries. Herstal probably derives its name from being a "Heerstelle" or permanent camp of the Franks. It is well known as the birthplace and family seat of Pippin, the major-domo of the Austrasian kingdom, some few traces of whose castle are still pointed out above the town. And though it cannot maintain its claim to be the birthplace also of Charlemagne, it was undoubtedly a frequent place of residence for this greatest of the Carolingians; and in 870 it gave its name to the treaty by which Charles the Bald and Lewis the German decided the partition of Lotharingia. The lordship of Herstal passed to the house of Nassau in 1444; and in 1702, on the death of William III. of England, its possession was disputed between the house of Orange and the king of Prussia. The decision of the courts was given in 1714 in favour of Prussia; but the new possessors, finding the feelings of the people of Herstal against them, sold the lordship to Liège

for 140,000 thalers. Another Herstal, distinguished as the Saxon, was the place where Charlemagne had his winter quarters in the year 797. It is now the village of Herstelle on the Weser, in the government of Minden.

HERTFORD, COUNTY OF, HERTFORDSHIRE, OR HERTS, an inland county in the south-east of England, is situated between $51^{\circ} 36'$ and $52^{\circ} 5' N.$ lat. and $0^{\circ} 13' E.$ and $0^{\circ} 45' W.$ long. It is bounded on the N. by Cambridgeshire, N.W. by Bedfordshire, E. by Essex, S. by Middlesex, and S.W. by Buckinghamshire. The area comprises 391,141 acres or 611 square miles.

The aspect of the county is pleasant and picturesque, its surface being broken by gentle undulations which in some parts form a quick succession of hills and valleys. The highest summit is Kensworth Hill on the border of Bedfordshire, about 910 feet above sea-level. Fine oak and other trees are grown in the hedges, and from being pruned obliquely they form high walls of living timber shading narrow winding lanes. The arable and pasture lands of the farms are intermingled with the parks and ornamental woods of the country seats which are scattered thickly throughout the county. These features, varied by its winding rivers, impart to it a peculiar beauty, while in luxuriance it is not surpassed by any county in England.

The principal rivers are the Lea, which, rising some miles beyond Luton in Bedfordshire and entering Hertfordshire at Hemmell, flows south-east to Hatfield and then east by north to Hertford and Ware, whence it bends southward, and passing along the eastern boundary of the county falls into the Thames a little below London, having received in its course the Maram, the Beane, the Rib, and the Stort, which all flow southward in the north-eastern part of the county, the Stort for some distance forming the boundary between it and Essex; the Colne, which, flowing through the south-western part of the county, falls into the Thames at Brentford, having received in its course the Ver, the Bulborne, and the Gade; the Ivel, which, rising in the north-west of the county, soon passes into Bedfordshire. The New River, one of the water supplies of London, made by Sir Hugh Myddelton (1607-13), has its source in some springs near Ware, and runs parallel for many miles with the Lea. The Grand Junction Canal from London to Birmingham traverses the south-west corner of the county, passing by Watford and Berkhamstead. There are mineral springs in the parishes of Chipping Barnet, Northaw, and Watton.

Geologically the county consists of Cretaceous and Tertiary rocks, the greater part being Lower, Middle, and Upper Chalk, which in the south-eastern part of the county are covered by Tertiary deposits belonging to the London basin. Over a large part of the eastern side of the county there are superficial deposits of glacial origin, and on the western side there are traces of the Lower Tertiary beds having formerly extended over a much wider area, outliers of the beds being of not unfrequent occurrence, and the drift deposits on the chalk hills being largely composed of their debris. The vales traversed by the rivers and streams exhibit in the bottoms a rich sandy loam; the sloping sides are covered by loams of inferior quality; and the flat surface of the high ground is generally formed of a loam of reddish hue tending towards common clay, with which it is often confounded.

The climate is mild, dry, and remarkably salubrious. On this account the London physicians were accustomed to recommend the county for persons in weak health, and it was so much coveted by the noble and wealthy as a place of residence, that it was a common saying—"He who buys a home in Hertfordshire pays two years' purchase for the air."

According to the agricultural returns for 1879, the total area of arable land was 339,137 acres, of which 145,666 acres were under corn crops, 39,443 under green crops, 35,416 under rotation grasses, 97,543 permanent pasture, and 18,111 fallow. The area under woods was 20,714 acres. It will thus be seen that the main produce of Hertfordshire is corn. The principal crop is wheat, which in 1879 occupied 59,363 acres. The varieties mostly grown are white, and they are not surpassed by those of any county in England. Wheathampstead on the river Lea receives its name from the fine quality of the wheat grown in that district. Of barley, which is largely made use of in the county for malting purposes, there were 49,129 acres in 1879, and of oats only 25,779. Little or no rye is grown, and of pease and beans together there were in 1879 only a little over 11,000 acres. Of green crops, turnips and Swedes occupied in 1879 an area of 21,578 acres, while potatoes had only 2576. Vetches are largely grown for the London stables, extending to 8191 acres in 1879. The greater part of the permanent grass is made use of for hay. There are some very rich pastures on the banks of the river Stort, extending from Hertford to Hockeril on the borders of the river Lea, and also near Rickmansworth, where they are watered by the river Colne. The percentage of cultivated area in 1879 was 86.7 instead of 85.1 in 1870; of area under corn crops 37.2 instead of 38.5; under green crops 10.1 instead of 11.5; under rotation grasses 9.8 instead of 10.2; and of permanent pasture 24.9 instead of 22.0. The most common system of rotation is the five-course—turnips or fallow, barley, clover, wheat, oats. In the south-west part of the county large quantities of cherries and apples are grown for the London market. On the best soils nearest to London culinary vegetables are forced by the aid of rich manure, and more than one crop are sometimes obtained in a year.

Generally speaking, the quantity of stock kept is small. Not much attention is paid to the breeds of cattle, but among cows the Suffolk variety is the most common. The number of cattle in 1879 was only 31,754, or an average of 9.3 to every 100 acres under cultivation, the average for England being 11.9, and for the United Kingdom 21.0. Of these the number of cows in milk or in calf was 11,802. The number of horses in 1879 was 15,022, or an average of 4.4 to every 100 acres, the average for England being 4.5 and for the United Kingdom 4.1. The horses used for agricultural purposes are chiefly Suffolk punches. The number of sheep in 1879 was 171,133, or an average of 50.4 to every 100 acres under cultivation, the average for England being 75.3, and for the United Kingdom 68.0. The principal kinds are the Southdown and Wiltshire, and a cross between Cotswolds and Leicesters. Pigs in 1879 numbered 30,404, or an average of 8.9 to every 100 acres under cultivation, the average for England being 7.2, and that for the United Kingdom 6.7.

In Hertfordshire the number of resident proprietors is very large, which circumstance, as well as the proximity to London, has doubtless greatly aided the development of agricultural enterprise. The average extent of the farms is about 200 acres, and the modern improvements are everywhere adopted.

According to the return of owners of land for 1872-73, the soil was divided among 12,387 proprietors, holding land the gross annual rental of which was £1,163,192. Of the owners 77 per cent. held less than one acre, and the total annual value for the county was £2, 17s. 3½d. per acre. There were only eight proprietors who held upwards of 4000 acres, viz., Marquis of Salisbury, Hatfield, 13,389; Abel Smith, Watton, 10,212; Earl Cowper, Panshanger, 10,122; Earl of Verulam, Gorhambury, St Albans, 8625; Earl Brownlow, Ashridge Park, 8551; Lord Deere, The Hoe, Welwyn, 7100; Charles C. Hale, King's Walden, 6558; and Earl of Essex, Cashiobury Park, Watford, 6157. W. H. Baker, Bayfordbury, comes next with 3911 acres.

The staple trade of the county is in corn and malt, most of which is sent to the metropolis. There are numerous flour-mills, as well as breweries, tanneries, tile-works, and coach factories, but the principal manufactures are paper, silk, and straw plait.

Hertfordshire is so much intersected by railways that no place in any part of the county is more than 5 miles distant from a station. On the eastern border there is the Great Eastern, with branches to Hertford and Buntingford. The middle of the county is traversed by the Great Northern, with branches from Hatfield to Hertford, Luton, Dunstable, and St Albans, and from Hitchin to Royston, and thence to Cambridge. The Midland passes through St Albans, with branches to the Great Northern and London and North-Western. The London and North-Western traverses the south-western corner.

The county comprises 8 hundreds, and the municipal boroughs of Hertford and St Albans. The principal towns are the municipal and parliamentary borough of Hertford (municipal borough, 7169), the city of St Albans (8293), Hitchin (7630), Watford (7461), Bishop Stortford (6250), Hemel-Hempstead (5994), Ware (4217), Berkhamstead (4083), Tring (4045), Barnet (3720). For parliamentary representation the county is an undivided constituency, and returns three members, while one member is returned for the borough of Hertford. Hertfordshire is in the south-eastern circuit. There were formerly two courts of quarter sessions, one for the

county and one for the liberty of St Albans, which liberty had also a separate commission of the peace, but the county and the liberty are now amalgamated, though prisoners are tried both at Hertford and St Albans. The jail for the county is at the latter city. The county is divided into fifteen petty sessional divisions, and for some purposes into two divisions, those of Hertford and the liberty of St Albans. The boroughs of Hertford and St Albans have commissions of the peace. Ecclesiastically the county is in the diocese of St Albans, and contains 138 civil parishes, townships, or places, as well as parts of other parishes extending into adjoining counties. The total population in 1871 was 192,226, of whom 93,244 were males and 98,982 females. The population in 1861 was 173,280. Since the first census in 1801 it has increased by 94,833, or 97 per cent.

History and Antiquities.—Previous to the Roman invasion the Celtic inhabitants of Hertfordshire, as of the other parts of South Britain, had been subdued by the Belgæ. In 54 B.C. Cassivelaunus, the chief of the Cassii, led an army to oppose Caesar, but he was defeated, and his capital Verulam, near the present town of St Albans, taken. At Verulam and Berkhamstead traces of ancient British works may yet be seen; and it has been conjectured that British stations existed at Royston, Braughing, and various other places in the county. Numerous British epins have been found at Verulam. Three principal British roads or trackways crossed the county: Watling Street passed through its south-west corner, in a north-west direction by St Albans to Dunstable; Ermine Street entered the south-east corner at Little Heekgate, whence it proceeded by Gough's Oak and Broxbourne Bury to Ware, holding thence much the same course as the present road by Buntingford to Royston; Icknield Street, from Dunstable to Royston, crossed the north-west corner. There are numerous barrows at Royston, and along the range of chalk hills at the northern edge of the county. Hertfordshire was the scene of an important part of the struggle carried on against the Romans by Caractacus about 44 A.D.; and during the rebellion of Boadicea the Romans were defeated on the road from Verulam to Colchester, and Verulam itself was taken and devastated by the Britons. The shire was included within the Roman province of Flavia. Among the Roman stations within its limits were the capital *Verulamium*, which the Romans rebuilt and fortified; *Forum Diane*, not far from Dunstable; *Ad Fines*, supposed to have been near Braughing, where there are remains of a vallum with fosse; and probably others at Royston and Bishop Stortford. Watling Street and Ermine Street were causewayed as Roman roads, and other branch roads traversed the county in various directions. Roman antiquities have been found at Verulam, Braughing, Royston, Wilbury Hill (where there are remains of an ancient camp), Cheshunt, Heinel-Hempstead, and Bishop Stortford. After the conquest of England by the Anglo-Saxons, Hertfordshire was included partly in Mercia and partly in Essex. It was the scene of frequent contests between the Saxons and the Danes. In 896 the Danes, having anchored their vessels in the Lea near the town of Ware, laid siege to Hertford, whereupon Alfred the Great, by dividing the stream into three channels, stranded their vessels and compelled them to retreat to the Severn. After the battle of Senlac in 1066, William the Conqueror, in order to force the earls to hurry home from London to their earldoms, crossed the Thames at Wallingford and marched into Hertfordshire, where at Berkhamstead an attempt was made by the abbot of St Albans to stop his course by cutting down the trees; and at a meeting of nobles held at the town he took an oath to rule according to the ancient laws and customs of the country. The subsequent events of historic importance connected with the county are the capture of Hertford castle by the revolted barons under the French dauphin, December 6, 1216; the battle between the royalists and the armies of the White Rose at St Albans, May 22, 1455, in which Henry VI. was wounded and taken prisoner; a second battle near St Albans, 17th February 1461, in which the earl of Warwick was defeated by Queen Margaret; the defeat near Barnet of the earl of Warwick by Edward IV., 14th April 1471; and the arrest by Cromwell of the high sheriff of the county as he was proceeding to St Albans for the purpose of proclaiming by order of Charles I. that all the Parliamentary commanders were rebels and traitors.

Among the objects of antiquarian interest may be mentioned the cave of Royston, rediscovered in 1742, doubtless at one time used as a hermitage, and containing rude carvings of the crucifixion and other sacred subjects; Waltham cross, in the Pointed style of architecture, (restored in 1833), erected to mark the spot where rested the body of Eleanor, Queen of Edward I., on its way to Westminster for interment; and the Great Bed of Ware referred to in Shakespeare's *Twelfth Night*, for many years shown to visitors at the Crown Inn of that town, and in September 1864 put up to auction at the Saracen's Head for 100 guineas and bought in. The principal monastic buildings are the noble pile of St Albans abbey, founded about 793 in honour of the first Christian martyr of Great Britain; the remains of Sopwell Benedictine nunnery near St Albans, founded in 1140; the remains of the priory of Ware, dedicated to St Francis, and originally a cell to the monastery of St Ebrulf at Utica in Normandy;

and the remains of the priory at Hitchin built by Edward II. for the White Carmelites. Among the more interesting churches may be mentioned those of Abbots Langley and Hemel-Hempstead, both of Late Norman architecture; Baldock, a handsome Gothic building supposed to have been erected by the Knights Templars in the reign of Stephen; Royston, formerly connected with the priory of the canons regular; Hitchin, built in the 15th century on the site of an older structure, with a fine porch in the Perpendicular style and an altarpiece by Rubens; Hatfield, dating from the 13th century; Berkhamstead, chiefly in the Perpendicular style, with a tower of the 16th century. The ruins of secular buildings of importance are the massive remains of Berkhamstead castle, Hertford castle, Hatfield palace, the slight traces at Bishop Stortford, and the earthworks at Anstie. Of the numerous mansions of interest only a few can be mentioned:—the Rye House, erected in the reign of Henry VI., tenanted by Rumbold, one of the principal agents in the plot to assassinate Charles II.; Moor Park, Rickmansworth, at one time the property of St Albans abbey, granted by Henry VII. to John de Vere, earl of Oxford, for some time in the possession of Cardinal Wolsey and subsequently of the duke of Monmouth, who built the present mansion, which, however, after it was sold by the duchess of Monmouth to Mr Styles, was eased with Portland stone, and received various other additions at a cost of £150,000; Knebworth, the seat of the Lyttons, originally a Norman fortress, rebuilt in the time of Elizabeth in the Tudor style, and restored in the present century; Hatfield House, the manor of which was granted to the abbey of St Ethelred at Ely by King Edgar, and with the palace was made over to Henry VIII., from whose reign it remained a royal residence until the time of James I., who exchanged it for the palace of Theobalds with Sir Robert Cecil, afterwards earl of Salisbury, by whom the present mansion in the Elizabethan style was erected, being founded in 1611; Panshanger House, now the principal seat of the Cowpers, a splendid mansion in the Gothic style erected at the beginning of the present century; Cashibury House, the seat of the earls of Essex, supposed to derive its name from the old British tribe Cassii, and the manor of which was formerly held by the abbot of St Albans, rebuilt in the beginning of the present century from designs by Wyatt, somewhat resembling those of Windsor Castle; Gorhambury House, formerly the seat of the Bacons, and the residence of the great chancellor, but rebuilt by the Grimstons. Among the eminent persons connected with the county were Nicholas Brakespear (Pope Adrian IV.), Francis Bacon, Sir John Mandeville, William Cowper, Charles Lamb, and Lord Lytton.

The old histories of Hertfordshire by Cox, Salmon, and Chauncey have been superseded by the splendid work of Clutterbuck, 3 vols. folio, 1815-27, and the laborious compilation now in course of publication by John Edwin Cussans.

HERTFORD, a town of England, capital of the above county, is situated in a sheltered valley on the river Lea, and on the Great Northern and Great Eastern Railways, 26 miles north of London by rail. It is somewhat irregularly built, but is neat, clean, and well-paved. The principal buildings are the shire-house or town-hall, erected on the site of the former edifice, and finished in 1771; the corn exchange, erected in 1858; the church of All Saints recently restored, a cruciform structure of the 14th century, with a square tower surmounted by a spire; the new church of St Andrews, occupying the site of the old one; the brick edifice which occupies the site of the ancient castle, and includes some portions of the old building; and the infirmary. The county jail has lately been sold under the provisions of the new Prisons Act. There are a large number of educational institutions, including the preparatory school for Christ's Hospital, London; Hale's grammar school for boys, the Cowper Testimonial school for boys, the Abel Smith Memorial school for girls, and the Green Coat school for boys and girls of poor parents who have never received alms. The town depends for its prosperity chiefly on agriculture. The trade is principally in wheat and wool, and a large quantity of malt is made for the London breweries. There are also breweries, iron foundries, and flour and oil mills. The population of the municipal borough in 1871 was 7169, and of the parliamentary borough 7894. The area of the municipal borough is 864 acres, and of the parliamentary borough 1123 acres.

The name Hertford is identified by Bede with *Herulford*, meaning red ford, but more probably it is a corruption of Hereford, meaning army ford, and indeed it is spelt in this way by Saxon authorities and in some monastic charters. In 673 a council was convened at Hertford by Theodore, Archbishop of Canterbury, at which two

Saxon-kings attended. The castle was erected about 905 by Edward the Elder, who at the same time rebuilt the town, which had in all probability been devastated by the Danes. Its custody and the government of the town were given by William the Conqueror to Peter de Valoignes. Subsequently it was surrendered to the crown. In the reign of John it was captured by the revolted barons headed by the dauphin of France. By Edward III. the castle was made the occasional prison of John II. king of France and David king of Scotland. Hertford is recorded as a borough in Domesday. It received its first charter from Queen Mary in 1554, and this was renewed and modified by Elizabeth, and confirmed and extended by James I. and Charles II. The borough sent two members to parliament from the reign of Edward I. to the 50th of Edward III., when the privilege was suspended until the reign of James I. Since the Reform Act of 1867 it has returned only one member.

HERTZ, HENRIK (1798–1870), Danish poet, was born of Jewish parents in Copenhagen, August 25, 1798. At that date it was unusual for Jews to enjoy a professional education, but young Hertz showed such marked literary bias that in 1817 he was sent to the university. His father having died in his infancy, and the family property having been destroyed in the bombardment of 1807, the boy was brought up by his relative, M. L. Nathanson, for many years editor of the principal Danish newspaper. Young Hertz was destined for the law, and passed his juridical examination in 1825. But his taste was all for polite literature, and in 1827 he came forward as a dramatic author by the publication of two plays, *Herr Burchardt and his Family and Love and Policy*; the latter enjoyed considerable success on the stage. In 1828 followed the comedy of *Flyttedagen*, which occupied itself with the humours of moving house on quarter-day. In 1830 he brought out what was a complete novelty in Danish literature, a drama in rhymed verse, *Amor's Strokes of Genius*. In the same year Hertz published anonymously *Gjengangerbrevene*, or Letters from a Ghost, which he pretended were written by Baggesen, who had died in 1826, and which were full of satirical humour and fine critical insight. The success of this book was overwhelming; Copenhagen talked of nothing else for a whole season; but Hertz preserved his anonymity, and the secret was not known until many years later. In 1832 he published a didactic poem, *Nature and Art*, and *Four Poetical Epistles*. *A Day on the Island of Als* was his next comedy, followed in 1835 by *The Only Fault*. Hertz passed through Germany and Switzerland into Italy in 1833; he spent the winter there, and returned the following autumn through France to Denmark. In 1836 his comedy of *The Savings Bank* enjoyed a great success. But it was not till 1837 that he developed his most important talent by writing the romantic drama of *Svend Dyring's House*, a beautiful and original piece, which still holds the stage. His historical tragedy *Valdemar Atterdag* was not so well received in 1839; but in 1845 he achieved an immense success with his lyrical drama *King René's Daughter*, which has been translated into almost every European language, and successfully acted all over the civilized world. To this succeeded the tragedy of *Ninon* in 1848, the romantic comedy of *Tonietta* in 1849, *A Sacrifice* in 1853, *The Youngest* in 1854. His lyrical poems appeared in successive collections, dated 1832, 1840, and 1844. From 1858 to 1859 he edited a very interesting literary journal entitled *Weekly Leaves*. He died in 1870. Hertz is one of the first of Danish lyrical poets. His poems are full of colour and passion, his versification has more witchcraft in it than any other poet's of his age, and his style is grace itself. He has all the sensuous fire of Keats without his proclivity to the antique. As a romantic dramatist he is scarcely less original. He has bequeathed to the Danish theatre, in *Svend Dyring's House* and *King René's Daughter*, two pieces which have survived the vicissitudes of forty years, and which are as popular as ever. He is a troubadour by instinct; he has little or

nothing of Scandinavian local colouring, and succeeds best when he is describing the scenery or the emotions of the glowing south.

HERTZEN, ALEXANDER (1812–1870), was born at Moscow in 1812, a very short time before the occupation of that city by the French. His father, Ivan Yakovlev, after a personal interview with Napoleon, was allowed to leave, when the invaders arrived, as the bearer of a letter from the French to the Russian emperor. His family attended him to the Russian lines. Then the mother of the infant Alexander (a young German Protestant of Jewish extraction from Stuttgart, according to A. von Wurzbach), only seventeen years old, and quite unable to speak Russian, was forced to seek shelter for some time in a peasant's hut. A year later the family returned to Moscow, where Herzen passed his youth,—remaining there, after completing his studies at the university, till 1834, when he was arrested and tried on a charge of having assisted, with some other youths, at a festival during which verses by Sokolovsky, of a nature uncomplimentary to the emperor, were sung. The special commission appointed to try the youthful culprits found him guilty, and in 1835 he was banished to Viatka. There he remained till the visit to that city of the hereditary grand-duke (afterwards Alexander II.), accompanied by the poet Joukofsky, led to his being allowed to quit Viatka for Vladimir, where he was appointed editor of the official gazette of that city. In 1840 he obtained a post in the ministry of the interior at St Petersburg; but in consequence of having spoken too frankly about a death due to a police officer's violence, he was sent to Novgorod, where he led an official life, with the title of "state councillor," till 1842. In 1846 his father died, leaving him by his will a very large property. Early in 1847 he left Russia, never to return. From Italy, on hearing of the revolution of 1848, he hastened to Paris, whence he afterwards went to Switzerland. In 1852 he quitted Geneva for London, where he settled for some years. In 1864 he returned to Geneva, and after some time went to Paris, where he died, January 21, 1870.

His literary career began in 1842 with the publication of an essay, in Russian, on *Dilettantism in Science*, under the pseudonym of "Iskander," the Turkish form of his Christian name,—convicts, even when pardoned, not being allowed in those days to publish under their own names. His second work, also in Russian, was his *Letters on the Study of Nature* (1845–6). In 1847 appeared his novel *Kto Vinovat?* (Whose Fault?), and about the same time were published in Russian periodicals the stories which were afterwards collected and printed in London in 1854, under the title of *Prervannuie Razskazui* (Interrupted Tales). In 1850 two works appeared, translated from the Russian manuscript, *Vom anderen Ufer* (From another Shore) and *Lettres de France et d'Italie*. In French appeared also his essay *Du Développement des idées révolutionnaires en Russie*, and his memoirs, which, after being printed in Russian, were translated under the title of *Le Monde russe et la Révolution* (3 vols. 1860–62), and were in part translated into English as *My Exile to Siberia* (2 vols., 1855). From a literary point of view his most important work is *Kto Vinovat?* a story describing how the domestic happiness of a young tutor, who marries the unacknowledged daughter of a Russian sensualist of the old type, dull, ignorant, and genial, is troubled by a Russian sensualist of the new school, intelligent, accomplished, and callous, without there being any possibility of saying who is most to be blamed for the tragic termination. But it was as a political writer that Herzen gained the vast reputation which he at one time enjoyed. Having founded in London his "Free Russian Press," of the fortunes of which, during ten years, he gave an interesting account in a book published (in Rus-

asian) in 1863, he issued from it a great number of Russian works, all levelled against the system of government prevailing in Russia. Some of these were essays, such as his *Baptized Property*, an attack on serfdom; others were periodical publications, the *Polyarnaya Zvezda* (or Polar Star), the *Kolokol* (or Bell), and the *Golosa iz Rossii* (or Voices from Russia). The *Kolokol* soon obtained an immense circulation, and exercised an extraordinary influence. For three years, it is true, the founders of the "Free Press" went on printing, "not only without selling a single copy, but scarcely being able to get a single copy introduced into Russia;" so that when at last a bookseller bought ten shillings' worth of *Baptized Property*, the half sovereign was set aside by the surprised editors in a special place of honour. But the death of the emperor Nicholas in 1855 produced an entire change. Herten's writings, and the journals he edited, were smuggled wholesale into Russia, and their words resounded throughout that country, as well as all over Europe. Their influence became overwhelming. Evil deeds long hidden, evil-doers who had long prospered, were suddenly dragged into light and disgrace. His bold and vigorous language aptly expressed the thoughts which had long been secretly stirring Russian minds, and were now beginning to find a timid utterance at home. For some years his influence in Russia was a living force, the circulation of his writings was a vocation zealously pursued. Stories tell how on one occasion a merchant, who had bought several cases of sardines at Nijni-Novgorod, found that they contained forbidden print instead of fish, and at another time a supposititious copy of the *Kolokol* was printed for the emperor's special use, in which a telling attack upon a leading statesman, which had appeared in the genuine number, was omitted. At length the sweeping changes introduced by Alexander II. greatly diminished the need for and appreciation of Herten's assistance in the work of reform. The freedom he had demanded for the serfs was granted, the law-courts he had so long denounced were remodelled, trial by jury was established, liberty was to a great extent conceded to the press. It became clear that Herten's occupation was gone. When the Polish insurrection of 1863 broke out, and he pleaded the insurgents' cause, his reputation in Russia received its death-blow. From that time it was only with the revolutionary party that he was in full accord, and it is by that section of Russian Liberals alone that his opinions are now considered of authority. For the great reforms, however, which followed the Crimean War, Russia is much indebted to the outspoken utterances of Alexander Herten, and will be so in all probability for the constitutional changes which are likely to follow the repressive measures of 1879.

In 1873 a collection of his works in French was commenced in Paris. A volume of posthumous works, in Russian, was published at Geneva in 1870. His *Memoirs* supply the principal information about his life, a sketch of which appears also in A. von Wurzbach's *Zeitgenossen*, pt. 7, Vienna, 1871. See also the *Revue des Deux Mondes* for July 15 and Sept. 1, 1854. *Kto Vinovat* has been translated into German under the title of *Wer ist Schuld?* in Wolfsohn's *Russlands Novellendichter*, vol. iii. The title of *My Exile in Siberia* is misleading; he was never in that country. (W. R. S. R.)

HERULI, ÆRULI, or ERULI, a nomadic and warlike German tribe who inhabited the northern shores of the Black Sea, but afterwards divided into various sections and wandered into different parts of Europe. They made their first appearance in history in the 3d century, as taking part with the Goths in their incursions against the eastern provinces of the Roman empire. In the 4th century they acknowledged the overlordship of the Gothic king Ermanric, but when Attila, king of the Huns, made his descent upon Gaul, they joined his standard. After the overthrow of the Huns, in which they suffered considerably, they established an organized and distinct confederacy on the banks

of the Danube, and under the leadership of Odoacer, assisted in 476 in the overthrow of the Western empire. Under their king Rudolf they in the beginning of the 6th century attempted the subjugation of the Longobardi, but were defeated and dispersed, some of them proceeding to Scandinavia, and others being allowed by the emperor Anastasius to settle on the south bank of the Danube. In the time of Justinian some of them embraced Christianity. A large portion of them afterwards joined the Gepidæ in their wars against the Eastern empire; but others who remained afforded Justinian important assistance in his wars against the Vandals and East Goths, so that they frequently fought against one another. About the end of the 6th century they became submerged and lost in other nations, and disappeared from historical records. The Heruli were bold, hardy, and extremely pugnacious. For a considerable period they retained intact their strong individuality, and presented a firm resistance to the influences of surrounding civilizations. They put to death without mercy the sick and the aged, and are said even to have offered human sacrifices.

HERVEY, JAMES (1714-1758), a popular religious writer of the 18th century, was born at Hardington, near Northampton, on February 26, 1714, and was educated at the grammar school of Northampton, whence in 1731 he passed to Lincoln College, Oxford. At the university he came under the influence of John Wesley and others of that school, and for some time manifested an inclination towards their theology; ultimately, however, while retaining his regard for the men and his sympathy with their religious aims, he adopted a thoroughly Calvinistic creed, and resolved to retain connexion with the Established Church. Having taken holy orders in 1737, he became curate to his father in the family livings of Weston Favell and Collingtree, to which he himself succeeded in 1752. There, under the disadvantage of very weak health, he laboured with great diligence in the discharge of his parochial duties, and also wrote numerous religious works, which, though of but slight literary or theological value, rapidly became highly popular, and in many English and Scottish houses, especially of the humbler class, took a place on the same shelf with the *Pilgrim's Progress* and the *Whole Duty of Man*. His earliest work, *Meditations and Contemplations*, containing "Meditations among the Tombs," "Reflexions on a Flower Garden," and a "Descant on Creation" (1746), and "Contemplation on the Night and Starry Heavens" (1747), said to have been modelled on Boyle's *Occasional Reflexions on various Subjects*, within fourteen years passed through as many editions. *Theron and Aspasio*, or a *Series of Letters upon the most important and interesting Subjects*, which appeared in 1755, and was equally well received, called forth some adverse criticism even from Calvinists, on account of tendencies which were considered to lead to antinomianism, and was strongly objected to by Wesley in his *Preservative against unsettled Notions in Religion*. Besides carrying into England the theological disputes to which Fisher's *Marrow of Modern Divinity* had given rise in Scotland, it also led to what is known as the Sandemanian controversy as to the nature of saving faith. Hervey died on December 25, 1758. A "new and complete" edition of his *Works*, with a memoir, appeared in 1797. See also *Collection of the Letters of James Hervey, to which is prefixed an account of his Life and Death* (1760).

HERVEY, JOHN HERVEY, LORD (1696-1743), the "Narcissus," "Sporus," and "Lord Fanny" of Pope's satire, a nobleman of political and social distinction in the reign of George II., was son of John first earl of Bristol, and was born on October 13, 1696. Educated and trained for public life at Westminster and Clare Hall, Cambridge, he became a

favourite at the court of the prince and princess (afterwards George, II. and Queen Caroline), to which Pope, Gay, Arbuthnot, Chesterfield, and other wits resorted, and which was celebrated for the beauty and accomplishments of its ladies, such as Miss Bellenden (afterwards duchess of Argyll), Miss Howe, Miss Lepell, and Mrs Howard, whose names will live for ever in the poetry of Pope, Gay, and Swift, and in the lively memoirs and correspondence of that brilliant circle. Hervey was married to Miss Lepell in 1720. Having entered the House of Commons as member for Bury (1725), he in 1730 received the appointment of vice-chamberlain to the king; in 1733 Sir Robert Walpole called him up to the House of Lords, where he proved a frequent and effective speaker; and in 1740 he succeeded Lord Godolphin as lord privy seal, which office he held until the Walpole administration was driven from power in 1742. Notwithstanding miserable health he continued to take an active part in politics until his death, which occurred on August 8, 1743. He was survived by four sons, three of whom became successively earls of Bristol. Destitute of any commanding talents or solid principle, a sceptic in religion and a profligate in morals, Lord Hervey was yet far above the intellectual rank assigned him by his merciless satirist, Pope. He wrote and spoke vigorously on public questions, was studious and laborious, a fair scholar, and a writer of pleasing occasional verses. The origin of the hostility which led to the allusion in the *Dunciad* (iv. 104) in 1728, and afterwards to the attacks in the *Prologue* and *Epilogue to the Satires*, remains obscure. "It would be now idle," as Mr Croker remarks, "to seek for a cause of quarrel which the parties were, a hundred years ago, unable or unwilling to explain; but may it not be sufficiently accounted for by the jealousies almost inevitable between persons of such similar and therefore discordant tastes and tempers, living together in a circle of tittle-tattle, scandal, and pasquinades?" Political differences had probably something to do with it, Lord Hervey and Lady Mary Wortley Montague (who shared with him the poet's enmity) having at the accession of George II. adhered to Walpole, while Pope and his brother wits were chiefly associated with the opposition. Lord Hervey left behind him *Memoirs of the Reign of George the Second, from his Accession to the Death of Queen Caroline*, which were not published until 1848, when they appeared in two volumes, edited, with a biographical notice, by Mr Croker. The work throws much light on the interior of the court—its coarseness, dulness, and immorality; but it is as degrading to the author as it is to the English monarchy, for Lord Hervey appears rather in the light of a court parasite and malignant gossip than in that of a fair historian or an English gentleman.

HERZEGOVINA, an Illyrian province, ethnographically belonging to the Serbo-Croatian nationality, under the titular dominion of the Turkish sultan, but since 1878 administered by Austria-Hungary. The Turks included it in the vilayet of Bosnia. It is bounded N. and E. by Bosnia, S. by Montenegro, and W. by Dalmatia, only touching the Adriatic by the narrow enclaves of Klek and Sutornia. The province extends about 117 miles in a south-east direction between 17° 10' and 20° 15' E. long. By the treaty of Berlin the Herzegovinian districts of Niksic and Dormitor have been placed under the government of the prince of Montenegro.

Population.—The Austrians have not yet (1879) had time to complete trustworthy statistics as to the population and resources of the province, and those published in the days of Turkish administration must be received with great reserve. The best statistical accounts of Herzegovina are those collected for the Austrian Government by the staff-

officers Majors Roskiewicz and Thoemmel, and their discrepancy is the best proof of the difficulties which have hitherto prevented an exact calculation.

According to Roskiewicz the population of Herzegovina amounted in 1868 to 230,000 souls. Thoemmel (in 1867) gives it as 207,970, of whom 101,348 were Slavoslavs or adherents of the Orthodox Greek Church, 56,000 Mahometans, 49,217 Roman Catholics, 1340 Gipsies, and 65 Jews. Dr Blau (late Prussian consul-general at Serajevo) fixes the Herzegovinian population in 1872 approximately at 230,000, viz., 130,000 of the Orthodox Greek Church, 55,000 Mussulmans, 42,000 Roman Catholics, 2500 Gipsies, and 500 Jews. Klaich, however, the most recent Slavonic authority on the province (1878), reduces the total population to 185,421. During the troubles that ensued on the insurrection of 1875, about two-thirds of the Christian population fled beyond the Dalmatian and Montenegrin border, and the fearful mortality among these refugees has largely diminished the Herzegovinian population during the last three years.

With the exception of the Gipsies, the Jews, and a small sprinkling of Osmanli officials, the whole population is Slavonic, the Mahometans being for the most part renegade descendants of the feudal nobility that had formed itself here before the Turkish conquest. Much of the old Slavonic customs and family life still holds among the Herzegovinian Mussulmans, and here as in Bosnia polygamy is unknown. The Herzegovinians are tall, broad, and darker, and of greater personal bravery than the Bosnians; they are brachycephalic. In frame as well as character they approach very nearly to the Montenegrin type, and in the mountain districts they are divided, like the Montenegrins and Albanians, into clans or nahias, whose loyalty is reserved for their own waiwodes or military chiefs. Their temperament is pre-eminently poetic, in so much that the recent insurrection has already given rise to many epic lays, which are recited to the sound of the guzla or Serbian lyre by the national minstrels. The Serbo-Croatian language is spoken in its purest form in Herzegovina, and the Narenta valley has been called the Serbian Val d'Arno. The Orthodox Greek population is chiefly settled in the district east of the Narenta; to the west of that river the population is mostly Roman Catholic, and the Mahometans inhabit the larger towns. According to the *Schematismus* of the Franciscan P. Bakula, the population of the capital Mostar amounted in 1873 to 29,116, of whom 20,306 were Mahometans, 5008 Greeks, and 2821 Roman Catholics. Of the other towns, Ijubuski has, according to Klaich, a population of about 3000 souls, Stolatz 3500, Foeha 10,000, Niksic (now under Montenegro) 4000, and Trebinje 8000.

Natural Features.—Herzegovina, which has been described as the Turkish Switzerland, is divided into a variety of mountain plateaus by the parallel ranges of the Dinaric Alps; and the whole country is bisected by the river Narenta, which cleaves its way through the mountains from the Bosnian frontier towards the Adriatic. The valley of the Narenta and its tributaries forms the main artery of the province. There is situated the capital Mostar; and a fine highroad, the only avenue of communication between Serajevo (Bosna Serai) and the Adriatic, follows the river bank from the Dalmatian frontier to the Bosnian. The "polyes" or mountain plateaus are the most characteristic feature of the country. The smaller towns and villages group themselves on their level and comparatively fertile surface, and the districts or cantons thus formed are walled round by a natural rampart of white limestone mountains. These "polyes" may be described as oases in what is otherwise a desert expanse of mountains. The surface of some, as

notably the great Mostarsko Blato, is marshy, and in spring forms a lake; others are watered by streams which disappear in swallow-holes of the rock, and make their way by underground channels either to the sea or the Narenta. The most conspicuous example of these is the Trebinjstina, which disappears in two swallow-holes in Popovopolje, and after making its way by a subterranean passage through a range of mountains, wells up in the mighty source of Ombla near Ragusa, and hurries in undiminished volume to the Adriatic. The climate of Herzegovina is cold in winter and oppressively hot (maximum 100° Fahr. in shade) in summer. The scirocco is a prevalent wind, as well as the bora, the fearful north-north-easter of Illyria, which, sweeping down the lateral valleys of the Dinaric Alps, overwhelms everything in its path. The snow-fall is slight, and, except on a few of the loftier peaks, the snow soon melts. In the valleys, as that of the Narenta, the flora approaches that of Dalmatia and Southern Italy, and olives, mulberries, figs, melons, pomegranates, grapes, rice, and maize flourish. The Dinaric Alps, which stretch across the province from N.W. to S.E., are as a rule barer and loftier than those of Bosnia. To the west of the Narenta, indeed, their flanks are in places covered with a forest growth of beech and pine, but north-east of that river they present for the most part a scene of lunar desolation. They are of the Tertiary formation common to the Mediterranean geological zone, but their limestone has a more dolomitic character than that of the Bosnian ranges. The group of mountains in the north-west bend of the Narenta, the Krabac, Lipeta, and Porim Planinae, attain altitudes varying from 4000 to 5000 feet; the dolomitic peaks of Orobac, Samotica, and Veliki Cap rise over 6000; Orien on the Dalmatian-Montenegrin frontier 6300; and Mount Dormitor, in the tract of Herzegovina now ceded to Montenegro, reaches a height of 8500 feet. The river Narenta is navigable for small steamers as far as Metkovitch, the Dalmatian frontier station, and for *trabacoli* as far as Chaplina beyond Gabella, but the narrow and rocky bed of the stream beyond this point makes it doubtful whether the navigation can ever be extended as far as Mostar.

Produce and Industries.—In mineral wealth Herzegovina cannot compete with Bosnia. Lignite exists in considerable abundance in the Narenta valley near Mostar, at Konjica, and at Stolac. Mineral springs occur near Ljubuska; asphalt towards Metkovitch and Drazovo on the Dalmatian frontier. Rice is cultivated in the Trebisat valley and about Ljubuska. Mulberries are cultivated in the Narenta valley for silkworms, which were introduced here by the famous vizier Ali Pasha, but the culture is at present small. The wine of Konjica and Mostar resembles Dalmatian, and might be excellent, and the Trebinje tobacco is celebrated. Previous to the insurrection the chief wealth of the inhabitants consisted in cattle. Roskiewicz estimates the numbers as 100,000 horned cattle, 1,200,000 sheep and goats, and 100,000 swine; but there has been a terrible decrease during the three years of anarchy. Before the insurrection the annual value of the exports of the province, consisting principally of sheep's wool, hides, wax, wine, and tobacco, amounted to about 18,170,000 piastres (£163,530). The imports, principally cloth and woollen goods, were estimated at 17,500,000 piastres (£157,500).

History.—The old Serbian zupa of Chelm or Zachlumje was incorporated in the banat of Bosnia by the ban Stephen in 1326. Afterwards exchanged for Primerje with the king of Hungary, it was reannexed by the ban Stephen Tvartko, afterwards first king of Bosnia, who granted it as a fief to his distinguished general Vlatko Hranich. Vlatko's grandson, known as Stephen Cosaccia from his birthplace Cosac, took advantage of the weakness of King Tvartko III. of Bosnia to transfer the immediate suzerainty of his county to the emperor Frederick IV., who in 1440 created him duke, or, as his Slavonic subject, borrowing the German word, expressed it, *Herzega*, of St Sava. This and the further title of keeper of St Sava's

sepulchre he derived from the tomb of the patron saint of Serbia in his monastery of Milesevo. From this time the Slav population of Illyria begins to know the dominions of Cosaccia as the "Herzegovina" or duchy, a general term which embraced, besides the former county of Chelm, the two old Serbian zupas of Tribunja and Primorje, also governed by the "Herzega." The original Herzegovina thus extended from the sea-coast of Dalmatia to the confines of Rascia. The duke was prevailed on at the parliament of Konjica to recognize the suzerainty of the Bosnian king; he fixed his residence at Mostar, which he greatly enlarged, and which has since remained the capital of Herzegovina. The shrewd policy of Stephen Cosaccia, which offered an asylum for the Bogomiles or Puritans of Bosnia, hounded from their homes by the bigotry of a priest-ridden king, was greatly instrumental in warding off for a while from the duchy the blow that overwhelmed Bosnia. The duke managed with Bogomilian help to defend Herzegovina with some success; and though in 1464 the country was overrun and rendered tributary by the sultan's hordes, it was not till 1483, twenty years after the final conquest and extinction of the Bosnian kingdom, that the Turkish Beglerbeg succeeded in dispossessing Stephen Cosaccia's son and successor Duke Vladislav. The whole country was now incorporated in the Sandjakate of Bosnia. At different times the Venetians succeeded in recovering for Christendom parts of Herzegovina, and by the peace of Carlowitz in 1699 and that of Passarowitz in 1718 Primorje or the Herzegovinian coast-land, Castelnuovo, and Risano were finally merged in Venetian Dalmatia, and have thus descended to the Austrians. The only remaining strips of Herzegovinian sea-coast, the narrow enclaves of Klek and Sutorina, were left to the Turks by Ragusan dread of Venetian contact, supported by the good offices of England. The history of Herzegovina under the Turks is to a great extent a blank: the viziers of Herzegovina who resided at Mostar imitated by their quasi-independence of their Bosnian superiors the defiant attitude adopted by the duke of St Sava to his Bosnian suzerain. Feudalism under a Mahometan guise continued to survive here. The spahis, begs, or agas were merely mediæval lords who had apostatized to Islam. They kept their ancestral castles, their banners, their mediæval title deeds and patents of nobility. They exacted feudal service from their serfs and retainers. They indulged in the mediæval passion for hawking. One of these Mahometan nobles, Ali, aga of Stolac, did such good service for Sultan Mahmoud in his struggle with the Bosnian magnates that he was made vizier of Herzegovina, which was freed for a while from dependence on the Bosnian government. The reforms of Sultan Mahmoud did not by any means remove the grievances of the royal population of Herzegovina. The serfs had now to satisfy the extortion of imperial tax-farmers and excisemen as well as the demands of their feudal lords. The begs and agas continued to exact their forced labour and a third of the produce; the central Government levied a tithe which at the date of the outbreak had become an eighth. Three kinds of cattle tax, the tax for exemption from military service levied on every infant in arms, forced labour on the roads, forced loan of horses, a heavy excise on grapes and tobacco, and a variety of lesser taxes combined to burden the Christian peasants; but what was more galling than the amount, was the manner in which these various taxes were extorted,—the iniquitous assessment of tax-farmers and excisemen, and the brutal licence of the zapchiehs who were quartered on recalcitrant villagers. Meanwhile the prodigal expenditure of the imperial voluptuary at Stambul and the peculation of his ministers hurried on the crisis. The public bankruptcy of Turkey put the last straw on the royal's back. On July 1, 1875, the villagers of Nevesinje, which gives its name to a mountain plateau east of Mostar, unable to bear the extortion of the tax-farmers, and goaded to madness by the outrages inflicted on them by the zapchiehs and bashi-bazouks, rose against their oppressors. The insurrection rapidly spread through Herzegovina and thence to Bosnia. The Herzegovinians under their leaders Peko Pavlovich, Socica, Ljubibratic, and others held out for a year against all the forces that Turkey could dispatch against them, and in two struggles in the gorge of Muratovizza alone the Turks lost over 2000 men. In July 1876 the principalities joined in the struggle; the Russo-Turkish war followed, and by the treaty of Berlin the government of Bosnia and Herzegovina was confided to Austria-Hungary, while Niksich and the country about Mount Dormitor were detached from Herzegovina and annexed to Montenegro. On July 31, 1878, the Austrian troops crossed the Herzegovinian frontier, and the news roused the Mahometan fanatics to a desperate effort. On August 2d the Mahometans of Mostar, imitating the example of Seraievo, and believing themselves betrayed by the Turkish Government, rose *en masse*, murdered the Turkish governor and officials, and proclaimed a ulema head of a provisional government. The Austrians, however, pressed forward, and crushing some ineffectual efforts at resistance entered Mostar on the 6th of August. By the 29th of September the reduction of Herzegovina was completed by the capture of the hillfort of Klobuk. Since the completion of the occupation, the government of the province has been under the military governor at Seraievo, controlled by the foreign office at Vienna. The sultan still remains sovereign *de jure*, nor

have the Austro-Hungarian administrators as yet been able to regulate the agrarian difficulty which lies at the root of all the evils that have afflicted the province.

HERZOGENBUSCH, or 's HERTOGENBOSCH. See BOIS-LE-DUC.

HESEKIEL, GEORGE LOUIS (1818-1874), German author and journalist, was born August 12, 1818, in Halle, where his father, a man of considerable distinction, was a preacher and inspector of schools. Hesekiel studied history and philosophy in Halle, Jena, and Berlin, and devoted himself in early life to journalism and literature. In 1848 he settled in Berlin, where he lived till his death, February 26, 1874, achieving a considerable reputation both as a writer of books and as editor of the *Neue Preussische Zeitung*. He attempted many different kinds of literary work, the most ambitious being perhaps his patriotic songs, of which he published a volume during the revolutionary excitement of 1848-49. Another collection—*Neue Preussenlieder*—appeared in 1864 after the Danish war, and there was a third in 1870—*Gegen die Franzosen, Preussische Kriegs- und Königslieder*. Among his novels may be mentioned *Vier Junker* (1864) and *Der Schultheiss vom Zeyst* (1875). By far the best known of his works is his life of Prince Bismarck—*Das Buch vom Fürsten Bismarck* (3d edition, enlarged, 1873). This biography, which has been translated into English by R. H. Mackenzie, is written from the point of view of an ardent admirer of the great chancellor. It is of no value as an estimate of his political importance, but it has acquired a certain popularity because of the mass of more or less interesting anecdotes which the author has brought together respecting both the public and the private life of his hero. It has lately, however, been rather thrust into the shade by the more piquant revelations of Herr Busch.

HESIOD, the father of didactic poetry in Greece, is placed by Herodotus before Homer, but not more than 400 years before his own epoch; and, though the settlement of the question must depend on the internal evidence of the Hesiodic poems, this testimony is corroborated by the Parian marble and the historian Ephorus. He probably flourished about nine centuries before Christ. His father had migrated from Cyme in Æolia to Bœotia, exchanging there a seafaring life for agriculture; and Hesiod and his brother, a scapegrace named Perses, were born at Ascra, near the base of Helicon and under the mountains which encircle Bœotia. Of this locality—whose claim to be his birth-place was disputed by the city Orchomenus on the score of possession of his relics—Hesiod's description differs from that of modern topographers in pronouncing the climate ungenial, with alternations of excessive heat and cold; but the poet's prejudice may have been influenced by the injustice of Bœotian law-courts, and it was at any rate here, as he fed his father's flocks beside Helicon, that he received his commission from the Muses to be their prophet and poet—a commission which he recognized by dedicating to them an eared tripod won by him in a contest of song at funeral

games in Eubœa, and extant at Helicon in the age of Pausanias (*Theog.*, 20-34; Pausan., ix. 31, § 3). But to this call were linked, no doubt, literary antecedents in Æolia, as well as local associations of music and poetry in Hellas. His earliest poem, the famous *Works and Days*, embodies the experiences of his life afield, and, interwoven with episodes of fable, allegory, and personal history, forms a sort of Bœotian shepherd's calendar. The first portion is an ethical enforcement of honest labour and dissuasive of strife and idleness (1-383); the second consists of hints and rules as to husbandry (384-764); and the third is a religious calendar of the months, with remarks on the days most lucky or the contrary for rural or nautical employments. The connecting link of the whole poem is the author's advice to his brother, who appears to have bribed the corrupt judges to deprive Hesiod of his already scantier inheritance, and to whom, as he wasted his substance lounging in the agora, the poet more than once returned good for evil, though he tells him there will be a limit to this unmerited kindness. In the *Works and Days* the episodes which rise above an even didactic level are the "Creation and Equipment of Pandora," the "Five Ages of the World," and the much-admired "Description of Winter" (by some critics judged post-Hesiodic). It is in the *Works and Days* especially that we glean indications of Hesiod's rank and condition in life, that of a stay-at-home farmer of the lower class, whose sole experience of the sea was a single voyage of 40 yards across the Euripus, and an old-fashioned bachelor whose misogynic views and prejudice against matrimony have been conjecturally traced to his brother Perses having a wife as extravagant as himself.

The other poem attributed to Hesiod or his school which has come down in great part to modern times is *The Theogony*, a work of grander scope, inspired alike by older traditions and abundant local associations. It seems that no more congenial task could have suggested itself to the Ascraean shepherd than to work into system, as none had essayed to do before, the floating legends of the gods and goddesses and their offspring. This task Herodotus attributes to him, and he is quoted by Plato in his *Symposium* (p. 178 B) as the author of the *Theogony*. The first to question his claim to this distinction was Pausanias, the geographer (200 A.D.). The Alexandrian grammarians had no doubt on the subject; and indications of the hand that wrote the *Works and Days* may be found in the severe strictures on women, in the high esteem for the wealth-giver Plutus, and in coincidences of verbal expression. If, too, as commentators assert, the proper beginning of the *Works and Days* is at verse 11—

Οὐκ ἄρα μόνον ἐὼν Ἐπίδων γένος, ἀλλ' ἐπι γαῖαν
ἔϊσι δῶμα,

it is hard to avoid the conclusion that the poet there corrects a statement made in his *Theogony* (225), where he had described Eris, the daughter of Night, as one and indivisible. One thing is clear, that, as Mr Grote puts it, it was the aim of Hesiod, or the member of his school who composed the *Theogony*, "to cast the divine functions into a systematic sequence,"—so welding into intelligible coherence the generations and genealogies of the deities of Hellas, whom Homer had dealt with in passing and scattered notices only. The *Theogony* consists of three divisions—(1) a cosmogony, or creation; (2) a theogony proper, recounting the history of the dynasties of Zeus and Cronus; and (3) a brief and abruptly terminated heroogony, or generation of heroes by immortal sires from mortal mothers; the starting-point not improbably of the Hesiodic poem, the *Eoiai*, or "Catalogues of Women," of which all but a few fragments are lost. Prefaced by an account of the Muses' visit to their bard, the *Theogony*

proceeds, from the spontaneous generation of Erebus and Night from Chaos, to detail a cosmogonic order at first corresponding with the Mosaic. The first ruler of creation, Uranus, is disabled and dethroned by Cronus, and Cronus in turn by his sixth son by Rhea, Zeus; but the chronicling of Titans and Cyclopes, of Nereids and Oceanids, divine rivers and water-nymphs, defies even the briefest enumeration. The poet has interwoven several episodes of rare merit, such as the contest of Zeus and the Olympian gods with the Titans, or the description of the prison-house in which the vanquished Titans are confined, with the Giants for keepers and Day and Night for janitors (735 seq.). Notable also is the version of the legend of Pandora given in the *Theogony* as compared with that in the *Works and Days*. The *Theogony* omits the part played in the earlier poem by Epimetheus in accepting Pandora at Jove's hands in spite of the counsel of Prometheus, as well as the mention of the casket of evils from which in the *Works and Days* Pandora lifts the lid with such woeful results.

The only other approach to a poem of Hesiod is the so-called *Shield of Hercules*, a piece of patchwork with which interpolators have done their worst. The opening verses are attributed by a nameless grammarian to the fourth book of *Æoiæi*. The theme of the piece is the expedition of Hercules and Iolaus against the robber Cycnus; but its main object apparently is to describe the shield of Hercules (141-317). C. O. Müller deems this description worthy of a place beside Homer's shield of Achilles in *Il. xiii.*, and recognizes in it the genuine spirit of the Hesiodic school. Titles and fragments of other lost poems of Hesiod have come down to us: didactic, as the *Maxims of Chiron*; genealogic, as the *Ægimius*; and mythic, as the *Marriage of Ceyx* and the *Descent of Theseus to Hades*.

A strong characteristic of Hesiod's style is his sententious and proverbial philosophy (as in *Works and Days*, 24-5, 40, 218, 345, 371). There is naturally less of this in the *Theogony*, yet there too not a few sentiments take the form of the saw or adage. With the poet's history, apart from the evidence of his poems, we have little acquaintance. There is reason to suppose that in later life he removed from Ascræ to Orchomenus, where, according to Pausanias, were his sepulchre and epitaph. Tradition has assigned a tragical ending to a life seemingly placid and unemotional; but the story that he met a violent death near the Locrian Cœneon in the territory of Naupactus, by reason of an intrigue with a sister of his host, or a guilty knowledge of such intrigue, is probably valueless except as evidence of the hero-worship of Hesiod in Locris and Bœotia (cf. Friedel, *Die Sage vom Tode Hesiods*, Leipzig, 1879). The poet will be remembered as the first of didactic poets, the accredited systematizer of Greek mythology, and the rough but not unpoetical sketcher of the lines on which Virgil wrought out his exquisitely finished *Georgics*.

Among the older editions of the Hesiodic poems may be mentioned those published at Venice in 1495 and 1537, and those of Heinsius (Leyd. 1622), Schrevelius (Leyd. 1650), Grævius (Amst. 1701), Robinson (Oxf. 1737); and among those of modern date, Paley (Lond. 1861), Lehrs (Leips. 1840, new ed. 1868), Schömann (Berl. 1869), Köchly and Kinkel (Leip. 1870), Flach (Berl. 1874). The *Works and Days* has been edited apart by Spohn (Leip. 1819), Vollbehr (Kiel, 1844), Lennep (Amst. 1847); and the *Theogony* by F. A. Wolf (Halle, 1783), Lennep (Amst. 1843), Schömann (Berl. 1869), and Flach (Berl. 1873). The *Fragments* were collected by Markscheffel (Leip. 1840). The many disputed questions associated with the name of Hesiod have given rise to a vast critical and polemic literature. In regard to the language of the poems the student may consult W. Clemm, "Krit. Beiträge zur Lehre vom Digamma" in Curtius, *Studien*, ix.; Dr H. Flach, *Das dialektische Digamma des Hesiodos* (Berl. 1876); Alois Rzach, *Der Dialekt des Hesiodus* (Leip. 1876). The composition and system

of the *Theogony* have been investigated by Kock (Breslau, 1842), Gerhard (Berl. 1856), Wolcker (Eberf. 1865), Leitschuh (Wurzburg, 1867), Schömann (Berl. 1868), Flach (Leip. 1874), Fritz Ehlung (Clausthal, 1875); and special studies on the *Works and Days* have been contributed by Twisten (Kiel, 1815), Ranke (Götting, 1838), Steitz (Leip. 1869), Betke (Münster, 1872), and Canina (Tur. 1874). Works of more general criticism are Creuzer and Hermann, *Briefe über Homer und Hesiod* (Heidelb. 1817); Thiersch, *Ueber die Gedichte des Hesiods* (Munich, 1813); J. P. Mahaffy, "Studies in Greek Literature" in *Hermæthena*, iv. The MSS. are discussed by Flach, *Die beiden ältesten Handschriften des Hesiod* (Leip. 1877); Kinkel, *De codic. Hesiodicis nonnullis in Anglia asservatis* (Heidelb. 1866); Wrobel, "Über eine neue Hesiodhandschrift" in *Sitzungsber.* of Vienna Academy, 1879. There are English translations of the Hesiodic poems by Cooke (Lond. 1728), Elton (Lond. 1815), and Banks (Lond. 1856); German translations by J. H. Voss (Heidelb. 1806) and Uschner (Berl. 1865); French translations by Leconte de Lisle (Par. 1869) and Patin (Par. 1872-3); and Italian by Chioldi (Cosenza, 1867) and Pozzuolo (Milan, 1873). (J. DA.)

HESPERIDES, maidens whose number is variously given as three, four, or seven, who guarded the golden apples which Earth gave Hera at her marriage to Zeus. They live far away in the west at the borders of Ocean, in other words at that point of heaven where the sun sets. Hence the sun (according to Mimnermus) sails in the golden bowl that Hephæstus made from the abode of the Hesperides to the land where he rises again. According to other accounts they dwell among the Hyperboreans, who live in quietness and calm, *i.e.*, they dwell in heaven among the souls of them that have died on earth. The golden apples grow on a tree which is guarded by an ever-watchful dragon. The sun is often in German and Lithuanian legends described as the apple that hangs on the tree of the nightly heaven, like the fleece of the sun-ram that was sacrificed and skinned, and the dragon, the envious power, keeps the light back from men till some beneficent power takes it from him. Heracles is the hero who brings back the golden apples to mankind again. Like Perseus, he first applies to the Nymphs, who help him to learn where the garden is. Arrived there he slays the dragon and carries the apples to Argos; and finally, like Perseus, he gives them to Athene. The Hesperides are, like the Sirens, beautiful singers, *λύφωροι*. They are said to be the daughters of Atlas; or, according to other accounts, they are the children of Erebus and Night, or Phorcys and Ceto, and are thus sisters of the Grææ, who also receive into their care the setting sun. Hesperides are introduced into the Argonautic legend, but it is doubtful if this is really antique, or only a poetic embellishment of the wanderings of the Argonauts.

HESS. Amongst numerous German artists of this name, the following particularly deserve attention.

HEINRICH MARIA HESS—VON HESS, after he received a patent of personal nobility—was born at Düsseldorf in 1798, and brought up to the profession of art by his father, the engraver Karl Ernst Christoph Hess. Karl Hess had already acquired a name when in 1806 the elector of Bavaria, having been raised to a kingship by Napoleon, transferred the Düsseldorf academy and gallery to Munich. Karl Hess accompanied the academy to its new home, and there continued the education of his children. In time Heinrich Hess became sufficiently master of his art to attract the attention of King Maximilian. He was sent with a stipend to Rome, where a copy which he made of Raphael's Parnassus, and the study of great examples of monumental design, probably caused him to become a painter of ecclesiastical subjects on a large scale. In 1828 he was made professor of painting and director of all the art collections at Munich. He decorated the Aukirche, the Glyptothek, and the Allerheiligencapelle at Munich with frescos; and his cartoons were selected for glass windows in the cathedrals of Cologne and Ratisbon. Then came the great cycle of frescos in the basilica of St Boniface at Munich,

and the monumental picture of the Virgin and Child enthroned between the four doctors, and receiving the homage of the four patrons of the Munich churches (now in the Pinakothek). His last work, the Lord's Supper, was found unfinished in his atelier after his death in 1863. Before testing his strength as a composer Heinrich Hess tried genre, an example of which is the Pilgrims entering Rome, now in the Munich Gallery. He also executed portraits, and twice had sittings from Thorwaldsen (Pinakothek und Schack collections). But his fame will rest on the frescos representing scenes from the Old and New Testaments in the Allerheiligencapelle, and the episodes from the life of St Boniface and other German apostles in the basilica of Munich. Here he holds rank second to none but Overbeck in monumental painting, being always true to nature though mindful of the traditions of Christian art, earnest and simple in feeling, yet lifelike and powerful in expression. Through him and his pupils the sentiment of religious art has been preserved and extended in the Munich school, and will not easily die out.

PETER HESS—afterwards Von Hess—was born at Düsseldorf in 1792, and accompanied his younger brother Heinrich Maria to Munich in 1806. Being of an age to receive vivid impressions, he felt the stirring impulses of the time, and became a painter of skirmishes and battles. In 1813–15 he was allowed to join the staff of General Wrede, who commanded the Bavarians in the military operations which led to the abdication of Napoleon; and there he gained novel experiences of war and a taste for extensive travel. In the course of years he successively visited Austria, Switzerland, and Italy. On Prince Otho's election to the Greek throne King Louis sent Peter Hess to Athens to gather materials for pictures of the war of liberation. The sketches which he then made were placed, forty in number, in the Pinakothek, after being copied in wax on a large scale (and little to the edification of German feeling) by Nilsen, in the northern arcades of the Hofgarten at Munich. King Otho's entrance into Nauplia was the subject of a large and crowded canvas now in the Pinakothek, which Hess executed in person. From these, and from battlepieces on a scale of great size in the Royal Palace, as well as from military episodes executed for the czar Nicholas, and the battle of Waterloo now in the Munich Gallery, we gather that Hess was a clever painter of horses. His conception of subject was lifelike, and his drawing invariably correct, but his style is not so congenial to modern taste as that of the painters of touch. He finished almost too carefully with thin medium and pointed tools; and on that account he lacked to a certain extent the boldness of Horace Vernet, to whom he was not unaptly compared. He died suddenly, full of honours, at Munich, in April 1871. Several of his genre pictures, horse hunts, and brigand scenes may be found in the gallery of Munich.

KARL HESS, the third son of Karl Christoph Hess, born at Düsseldorf in 1801, was also taught by his father, who hoped that he would obtain distinction as an engraver. Karl, however, after engraving one plate after Adrian Ostade, turned to painting under the guidance of Wagenbauer of Munich, and then studied under his elder brother Peter. But historical composition proved to be as contrary to his taste as engraving, and he gave himself exclusively at last to illustrations of peasant life in the hill country of Bavaria. He became clever alike in representing the people, the animals, and the landscape of the Alps, and with constant means of reference to nature in the neighbourhood of Reichenhall, where he at last resided, he never produced anything that was not impressed with the true stamp of a kindly realism. Some of his pictures in the museum of Munich will serve as examples of his manner. He died at Reichenhall on the 16th of November 1874.

HESSE, or HESSIA (in German *Hessen*), an old country of Germany, situated on both banks of the Rhine and Main, north and south of Frankfort, has had different boundaries at different times. Its greatest length was about 95 miles, while its breadth has varied considerably. Several detached portions of territory were also included in Hesse.

The earliest recorded inhabitants of the district were the Chatti, whose chief settlement Mattium, probably near Gudensberg, was destroyed by Germanicus in 15 A.D. The Chatti, merged in the Franks, migrated westward, and their place in Hesse was taken by the Saxons. Among these, when conquered by the German kings, several "gaus" or earldoms were founded, some of whose possessors after the death of Charlemagne rose to great power. Two families—those of Werner and of Giso, count of Gudensberg—became latterly the most important. In 1130 the heiress of the Gisos married the landgrave of Thuringia, who thus became the overlord of Hesse. In 1247 the Thuringian male line became extinct, and Hesse, along with the other possessions of the landgrave, was involved in a prolonged war of succession. In 1263 Sophia, duchess of Brabant and niece of the last landgrave, received by treaty the landgraviate of Hesse, as it was from that time called, and two years later resigned it in favour of her son, Henry the Child, the ancestor of the present house of Hesse. Till the death of Philip the Magnanimous in 1567, Hesse continued to be regarded as one state, though sometimes shared by two rulers; but at that date Philip's four sons divided the landgraviate into Hesse-Cassel, Hesse-Marburg, Hesse-Rheinfels, and Hesse-Darmstadt. Of these the second and third lapsed by inheritance in 1583 and 1604 to the others, which became the chief lines. The small landgraviate of Hesse-Homburg was formed in 1596 of part of Hesse-Darmstadt. Hesse-Darmstadt, since the annexation of the other two to Prussia in 1866, has been the only independent part of Hesse left, and generally receives the common name.

Hesse-Nassau is a province of Prussia, formed in 1866 from parts of Hesse-Cassel and the dukedom of Nassau. Hesse-Philippsthal was a collateral line of the house of Hesse-Cassel, founded in 1630, and extinct in 1820. Hess-Barchfeld, Hesse-Butzbach, Hesse-Rothenburg, Hesse-Rumpenheim, and Hesse-Wanfried were collateral lines of little importance.

For further information see Teuthorn, *Ausführliche Geschichte des Hessen*, 1777–80; Wenck, *Hessische Landesgeschichte*, 1783 and 1803; Pfister, *Ueber den Chattischen und Hessischen Stamm und die älteste Geschichte des Chattischen Stammes*, 1863; Hoffmeister, *Historisch-genealogisches Handbuch über alle Linien des Regentenhauses Hessen*, 1874; Rommel, *Geschichte von Hessen*, 1820–58, 10 vols.; Hejpe, *Hessische Kirchengeschichte*, 1876.

HESSE-CASSEL, in German *KURHESSEN*, *i.e.*, Electoral Hesse, now forming the government district of Cassel in the Prussian province of Nassau, was till 1866 a landgraviate and electorate of Germany, consisting of several detached masses of territory, to the N.E. of Frankfort-on-the-Main. It contained a superficial area of 3699 square miles, and its population in 1861 was 745,063.

The line of Hesse-Cassel was founded by William IV., surnamed the Wise, eldest son of Philip the Magnanimous. On his father's death in 1567 he received one half of Hesse, with Cassel as his capital; and this formed the landgraviate of Hesse-Cassel. Additions were made to it by inheritance from his brother's possessions, while, as compensation for losses sustained in the Thirty Years' War, a large part of the countship of Schaumburg and other territory was acquired towards the middle of the 17th century. Charles I., who ascended the throne in 1670, was the first ruler who adopted the system of hiring his soldiers out to foreign powers as mercenaries, as a means of improving the national finances. Frederick I., the next landgrave, had become by marriage king of Sweden, and on his death was succeeded in the landgraviate by his brother William VIII., who fought as an ally of England during the Seven Years' War. From his successor Frederick II., who had become a Roman Catholic, 22,000 Hessian troops were hired by

England for about £3,191,000, to assist in the war against the North American colonies. The reign of the next landgrave, William IX., was an important epoch in the history of Hesse-Cassel. Ascending the throne in 1785, he took part in the war against France a few years later, but in 1795 peace was arranged by the treaty of Basel. For the loss in 1801 of his possessions on the left bank of the Rhine he was in 1803 compensated by some of the former French territory round Mainz, and at the same time was raised to the dignity of Kurfürst or Elector William I. In 1806 he made a treaty of neutrality with Napoleon, but after the battle of Jena the latter, suspecting William's designs, occupied his country, and expelled him. Hesse-Cassel was then added to Jerome Bonaparte's new kingdom of Westphalia; but after the battle of Leipsic in 1813 the French were driven out and the elector restored. By the Vienna congress, where he intrigued in vain to be recognized as a king, several changes in the extent of his dominion were made. On his return to his sovereignty, William promised to grant his people a new and popular constitution; but just as the draft was ready to become law by his signature, he drew back, dissolved the diet, and continued to rule without again summoning it. His son, William II., who succeeded in 1821, pursued the same line of policy, and carried on the government without reference to the diet. The discontent which this conduct excited was intensified by the elector's shameless connexion with the countess of Reichenbach. Disturbances took place, and the elector, after attempting to pacify his people, appointed his son as regent in 1831, and withdrew to Frankfort, where he died in 1847. The regent, becoming Elector Frederick William I., startled by the Paris revolution of 1848, made many promises to the people, and carried some of them into effect, but on the reaction of 1850, which spread over all Germany, snatched at the first pretext for returning to the former order of things. He attempted to levy the usual taxes without obtaining the consent of his chambers, but the commotion thus caused was so great that he was forced to retire to Wilhelmshad, along with his very unpopular minister, Hassenpflug. He induced the diet of princes then assembled at Frankfort to support him, and Austrian and Bavarian troops entered Hesse-Cassel to enforce obedience. Prussia, in alarm, immediately occupied the northern part of the country, and a civil war was barely avoided by arrangement. The elector, however, scarcely changed his policy, and the next sixteen years were occupied with disputes between the chambers and the Government. In 1866 Hesse-Cassel joined Austria against Prussia. Prussian troops immediately overran the country, and on the treaty with Austria, the electorate was annexed to the Prussian kingdom. The elector was carried a prisoner to Stettin, and was only released on resigning his claims to the throne of Hesse-Cassel. He died in 1875.

See Wippermann, *Kurhessen seit den Freiheitskriegen*, 1850; Röth, *Geschichte von Hessen-Kassel*, 1856; Grafe, *Der Verfassungskampf in Kurhessen*, 1851; and works under HESSE.

HESSE-DARMSTADT, GRAND-DUCHY OF, the actual Hesse of the present day, is a state of Germany situated on the Rhine and Main, between Prussia on the north and Baden on the south. It consists of two large and several small detached portions of territory. The more northerly of the large portions forms the province of Oberhessen, and is completely surrounded by Prussia. The other, divided by the Rhine into the provinces of Starkenburg and Rheinhessen, is bounded on the N. by Hesse-Nassau, on the W. by the Rhine Palatinate and Rhenish Prussia, on the S. by Baden, and on the E. by Baden and Bavaria. The extent of the duchy is about 2965 square miles. Oberhessen is mountainous, having the Vogelsberg in the east with Tanfstein (2579 feet) as the highest summit in the country, and the Hausberg, a branch of the Taunus, in the south-west. In the south-east of Starkenburg is the Odenwald. Rheinhessen is occupied by fertile hills. The chief rivers are the Rhine, Main, Neckar, Lahn, and Fulda, with their tributaries. There are no lakes, but mineral springs abound in all the provinces. The climate is pleasant and mild in the river valleys and plains, but severe on the heights, especially in Oberhessen. Besides the usual domestic animals, deer of various kinds, wild swine, foxes, martens, and otters are found. Agriculture, including the breeding of horses and cattle, is actively encouraged by Government, and is the principal industry of the people. Forestry and vine-growing are also important, the latter being practised almost exclusively in Rheinhessen. The principal crops are millet, buckwheat, oats, and potatoes: but rabe (for oil), hemp, flax, tobacco,

and fruit are also cultivated. The manufactures embrace leather (enamelled and coloured), tobacco, cigars, shoes, furniture, pocket-books and similar goods, chemicals, matches, machinery, and various textile fabrics. Mining is carried on chiefly in Oberhessen. Iron, copper, manganese, graphite, lignite, salt, marble, and clay are the principal minerals, which are worked for home consumption. In 1878 there were produced in Hesse 45,300 tons of lignite, 91,724 tons of iron ore, and 13,250 tons of salt, representing in value about £62,100. Trade is tolerably important in Hesse. The following numbers of persons engaged in the various industries are taken from the industrial census of 1875:—Horticulturists, 292; fishermen, 65; miners, 1556; workers in stone, clay, glass, 4715; in metals, 8266; in machines, instruments, &c., 7202; in chemical industries, 2153; in lighting materials, soap, resins, &c., 1190; in textile industries, 8274; in paper and leather, 7600; in wood, 11,142; in food and drink, 19,923; in dress and washing, 21,629; in building, 1291; in polygraphic industries, 1291; in artistic industries, 412; in mercantile business, 17,593; in conveyance, 2273; in lodging and boarding, 6016—total, 134,383. The people are well educated; of the recruits in 1878–79 only 21 per cent. were unable either to read or write. There is a university at Giessen, and the schools, ordinary, technical, and theological, throughout the country are very numerous. The Protestant religion predominates, though the Roman Catholic faith is also recognized by the state. Darmstadt is the capital; Offenbach is the chief manufacturing town; Mainz has perhaps the most active trade. The other chief towns are Alsfeld, Lauterbach, Friedberg, Bingen, Bensheim, and Worms. The population in 1875 was 884,218. The government since 1820 has been a constitutional hereditary monarchy, assisted by two chambers, modified in 1856—the one of life members, mostly from among the nobility, the other of popular representatives, elected indirectly. The chambers must meet at least once every three years. The ministry of three is responsible to the nation. Hesse is represented in the imperial federal council by 3 votes, and in the reichstag by 9. The annual revenue for the finance-period 1876–78 was £872,375, and the expenditure £872,481. The estimated annual revenue for the period 1879–82 is £1,011,762, and the estimated expenditure £857,124. The public debt in 1879 was £2,041,397, chiefly incurred for railways. For additional statistics see GERMANY.

George I., youngest son of Philip the Magnanimous, received on his father's death in 1567 the upper countship of Katzenelnbogen, and, selecting Darmstadt as his residence, became the founder of the Hesse-Darmstadt line. Additions to the territory were made both in his reign and in that of his son, Louis V. The landgraviate, as it was at first styled, suffered severely from war and its attendant famines and plagues. The Thirty Years' War, a war of succession with Hesse-Cassel, and the Seven Years' War dealt heavy blows at its prosperity. Louis X., who succeeded his father in 1790, involved it in further contests. Joining at first the allies against France, he was compelled in 1793 by the latter power to sign a treaty of neutrality. By the treaty of Lunéville he gave up his possessions on the left bank of the Rhine, receiving as compensation a very much larger district on the right bank. From 1805 till 1813 he was compelled to supply Napoleon with a contingent of troops against the other Germans. In 1806, as member of the Confederation of the Rhine, he assumed the title of grand-duke Louis I. of Hesse. After the battle of Leipsic in 1813, when Napoleon was defeated, Louis again joined the allies. By the decision of the Vienna congress in 1815 considerable change in his dominions was made; but though he was forced to recognize the independence of Hesse-Homburg, which since the beginning of the century had been incorporated with Hesse-Darmstadt, his title of grand-duke was confirmed. Within his country a growing desire for political liberty had been making itself apparent, and in 1820 the grand-duke promulgated a new constitution. This was rejected by the people, and attempts were made in vain by successive diets to frame a constitution pleasing alike to the ruler and the ruled. Louis II.

succeeded his father in 1830. His policy in no degree lessened the popular discontent. His son Louis III., who succeeded in 1848, alarmed by the events in Paris of that year, and by commotions in his own country, gave way a little, but under the reaction of 1850 he again restored matters to their old state. Since that time, although no radical change has been effected, the liberal party in the state has been steadily gaining ground. In 1866 Hesse-Darmstadt supported Austria against Prussia, with the result that it had to pay a heavy indemnity and cede certain provinces, including the lately acquired Hesse-Homburg, to Prussia. In 1867 it entered the North German Confederation, and in 1870 the German Confederation. Louis IV. succeeded his uncle in 1877.

A list of works on Hesse is to be found in Walther's *Literarisches Handbuch für Geschichte und Landeskunde von Hessen*, 1841. See also Steiner, *Geschichte des Grossherzogthums Hessen*, 5 vols., 1833-4; Türckheim, *Histoire généalogique de la maison de Hesse*, 1819-20; Heber, *Geschichte des Grossherzogthums Hessen*, 1837; Dieffenbach, *Das Grossherzogthum Hessen in Vergangenheit und Gegenwart*, 1875; Voltz, *Uebersicht der geologischen Verhältnisse des Grossherzogthums Hessen*, 1852; and works under Hesse.

HE SSE-HOMBURG, a former landgraviate of Germany, consisted of two parts, the province of Homburg-vor-der-Höhe, on the right bank of the Rhine, and the lordship of Meisenheim (added in 1815), on the left bank, to the north of Frankfort-on-the-Main. It comprehended an area of 106 square miles; and its population in 1864 was 27,374. Homburg now forms part of the Prussian government district of Wiesbaden, and Meisenheim of the government district of Coblenz.

Hesse-Homburg was formed into a separate landgraviate in 1596, by Frederick I., son of George I. of Hesse-Darmstadt. By his two sons it was divided into the parts Hesse-Homburg and Hesse-Homburg-Bingenheim; but the latter returned by inheritance to the original line in 1681. In the reign of Frederick V. (1751-1820) Hesse-Homburg was in 1806 incorporated with Hesse-Darmstadt, but that state was obliged by the Vienna congress to recognize the independence of Hesse-Homburg, which at the same time was increased by the district of Meisenheim. Frederick V. became a member of the German Confederation in 1817. After his death, his five sons successively filled the throne. The last, Ferdinand Henry Frederick, granted a liberal constitution to his people, but in the reaction of 1850 cancelled it. On his death on March 24, 1866, the landgraviate reverted by inheritance to the grand-duke of Hesse-Darmstadt; but in September of the same year that ruler was forced to cede it to Prussia, in consequence of having supported Austria in the Seven Weeks' War.

HESSIAN FLY, a name originally given in the United States in 1776 during the War of Independence to a small fly very destructive to wheat, supposed to have been brought over in straw by the Hessian troops employed on the British side. It is a species of *Cecidomyia*, described under the name *C. destructor* by the American entomologist Say, and belonging to the Dipterous family *Cecidomyiidae*, the numerous members of which produce galls, distortions, and other injuries in the plants they attack. It was often thought that this insect occurred in England; but the indigenous English wheat-midge, also very destructive, is an allied species, *Diplosis tritici*. A species found in Hungary and Germany, where it has committed great damage, has been supposed to be the true Hessian fly, which has also been recorded from Minorca and Naples; Cohn notices its ravages in Silesia, and Künstler in Austria; and Kaltenbach (who identifies *C. secalina*, Loew, with it) says it is more or less common in Germany, and that it originally came from Europe. Nevertheless, many good authorities have considered that the destructive European fly is not identical with the North American insect, though closely allied to it, and of similar habits. In the United States this minute midge has been a dreadful scourge at times, even to the extent of causing local famine. The female lays 20 or 30 eggs in a crease of the leaf of the young plant, and the larvæ when hatched work their way between the leaf and the stalk, till they come to a joint, a little below the surface, where they remain, head down, sucking the sap, and turn to pupæ enclosed in a covering; this is known as the "flax-seed" condition. The injury occasioned is not detected until the plant grows higher. There are

two broods every year, one reaching the fly state in May, the other in August or early in September; as the fly only lives a few weeks, wheat that is sown so late as not to come up until the second brood has disappeared escapes harm. The usual result of the attack is that small aborted ears only are formed, the few grains of which shrivel and will scarcely ripen, the straw also being of inferior quality. The perfect insect is smaller than the common gnat, which it somewhat resembles, and from which its size and more simple antennæ distinguish it. The larvæ are spindle-shaped and reddish-white, with the intestinal canal showing through the skin when full grown; they are about one-seventh of an inch long, and are provided with small hooks near the head; at this stage they group themselves in regular rings round the stem attacked. A very minute natural parasite, *Semioteilus destructor*, belonging to the division *Pteromalides* of the Hymenopterous family *Chalcididae* is, luckily for agriculturists, usually so plentiful as to be able to keep down the fly, on the larvæ and pupæ of which its own larvæ feed.

Besides the original account by Say (in the *Journal of the Academy of Natural Science*, Philadelphia, 1817), his countryman, Dr Asa Fitch, has published a history of this insect in the *Transactions of the New York State Agricultural Society*, 1846; and in England the celebrated entomologist Kirby gave an account of it in the *Magazine of Natural History*, 1829. It is figured in the *American Naturalist*, vol. ii. p. 163. A map showing its distribution will be found in Hayden's Report of the United States Geological and Geographical Survey for 1875.

HESSUS, HELIUS EOBANUS (1488-1540), a distinguished German humanist of the 16th century, was born January 6, 1488, at Bockendorf near Frankenberg in Hesse. His family name is not known: the baptismal name Eobanus he owed to a local saint; Hesus merely indicates the land of his origin; while the prenomem Helius was assumed by himself partly with reference to the sun-god, patron of poets, and partly also, it is said, with reference to the fact that he had been born on a Sunday. His early education was received in the monastery of Haina, where his father held a menial position, and afterwards at Frankenberg; in 1503 he entered the university of Erfurt, where in 1505 Crotus Rubianus and Ulrich von Hutten became his fellow-students and his firm friends. Though devoting himself enthusiastically to the composition of Latin verse, in which he soon became an acknowledged master, he was far from neglecting the other studies of the place, and shortly after his graduation he held for a short time the post of rector of the St Severus school. Compelled by disturbances to leave Erfurt in 1510, he for five years led a somewhat wandering life, in the course of which he passed some time in Leipsic as a student of law; in 1515 he returned to his former post at Erfurt, and in 1516 became professor of belles-lettres. He was now prominently associated with Reuchlin, Peutingier, Mutianus, as well as with Crotus Rubianus and Hutten; and from the first he fully identified himself with the cause of Luther and the Reformation. In 1526 he went as teacher of rhetoric and poetry to Nuremberg, but in 1534 returned to Erfurt, whence in 1536 he was called to the chair of poetry and history in Marburg. There he died October 5, 1540.

Hesus was generally regarded by his contemporaries both in Germany and elsewhere as the foremost Latin poet of the age; "if Erasmus was the modern Cicero, Eobanus was Virgil and Ovid." His most popular works were a translation into Latin distichs of the Psalms, which passed through more than forty editions, and Latin hexameter translations of Theocritus and of the *Iliad*. He also published *Silvæ*, a collection of idylls, epigrams, and occasional pieces, and a series of Christian *Heroidæ*, in imitation of Ovid. His *Epistolæ* were edited by his friend Joachim Camerarius, who also published his Life (1553). See the monographs of Herz (*H. E. Hesus, ein Lehrer u. Dichterleben aus der Reformationszeit*, 1860), Schwetzel (*H. E. Hesus, ein Lebensbild aus der Reformationszeit*, 1874), and Krause (*H. E. Hesus, sein Leben u. seine Werke*, 1879); also Strauss, *Ulrich von Hutten* (1858; 2d ed. 1871; Engl. transl. 1874).

HESTIA, a Greek goddess, who is probably the latest in origin of the greater deities. She seems to belong to a particular stage in the advance of civilization, and to embody the religious sanction that confirmed the social system then reached. When we compare her worship with that of Agni, the nearest parallel in the Vedic period, we see that the Greeks made this advance after they had separated from the Aryau conquerors of India. Agni is invoked in the *Rig Veda* as the brother, friend, and helper of men, as dwelling with them and mediating between them and the gods. But beyond this Hestia is the hearth-fire as the centre of an association, wider or narrower, which meets in common at the hearth. She is not mentioned in Homer; in the *Odyssey* sometimes one swears by Zeus, the table and the hearth, *i.e.*, by Zeus as the god of the family both in its external relation of hospitality and its internal unity round its own hearth. Hence we have the Zeus *ἑστίαναξ*, *ἑστίουχος*, *ἑφέστιος*. The former of these two ideas is too delicate and fine ever to become more than a mere aspect of Zeus, but the second gradually formed itself into a distinct worship, in which the already existing worship of the fire was merged. The fact that Hestia is not mentioned in Homer shows that her worship was not so universally acknowledged at the time which these poems reveal to us. Perhaps we may see in the connexion of the Latin Jupiter and Vesta at Lavinium a relic of the original connexion of the two; and the fact that the worship of this same goddess under the same name (they are only two forms of the feminine of the passive participle of the root *vas*, burn) is found in Latium and Greece affords strong evidence of a specially close connexion between the two races. We find therefore in Hestia relics of the old pre-Greek worship; she is the altar-fire, presiding over all sacrifices, and sharing in the honours of all the gods. The opening sacrifice was offered to Hestia; to her at the sacrificial meal the first and the last libations were poured. The fire of Hestia was always kept burning, or if by any mischance it were extinguished, only sacred fire made by friction, or got direct from the sun, might be used to rekindle it (see Kuhn, *Herabkunft*). But beyond this she is the goddess of the family union, the personification of the idea of home (see Welcker, *Gr. Gött.*, ii. 694), the protectress along with Zeus of the suppliants who fled for refuge to the hearth. To her therefore is ascribed the art of housebuilding. Hestia and Hermes are often united as the representatives of home and private life on the one hand, and of all business and outdoor life on the other. The city union, moreover, is just the family union on a large scale; it has its centre in the prytaneum, where the common hearth-fire round which the magistrates meet is always burning, and where the sacred rites that sanctify the concord of city life are performed. From this fire, as the representative of the life of the city, was taken the fire wherewith that on the hearth of a new colony was kindled. As patroness of the deliberations held in the prytaneum, Hestia is surnamed *βουλαία*. Even larger unions than the city had their central fire: in Tegea was the Hestia of the Arcadians; and it is probable that the Achæans had theirs at Æginium. In the later mystic philosophy Hestia became the hearth of the universe, the eternal fire at the centre of the world.

As Hestia had her home in the prytaneum, special temples to her rarely occur. There was one in Hermione, where the only symbol of the goddess was a fire always burning on the hearth. We also hear of her house at Olympia. Her statue stood in the prytaneum at Athens beside that of Peace. Though many statues of the Roman Vesta are preserved, more or less based on the Greek conception of Hestia, yet no really Greek representation of the goddess has come down to us.

HESYCHASTS (*ἡσυχασταί* or *ἡσυχάζοντες*, also called *ὀμφαλόφυγοι*, Umbilicani, and sometimes referred to as Euchites, Massalians, or Palamites), a quietistic sect which arose among the monks of the Greek Church, and especially of Mount Athos, during the later period of the Byzantine empire, and owing to various adventitious circumstances came into great prominence politically and ecclesiastically for a few years about the middle of the 14th century. Their opinion and practice will be best represented in the words of one of their early teachers (quoted by Gibbon, *Decline and Fall*, c. 63):—"When thou art alone in thy cell shut thy door, and seat thyself in a corner; raise thy mind above all things vain and transitory; recline thy head and chin on thy breast; turn thine eyes and thy thought towards the middle of thy belly, the region of the navel; and search the place of the heart, the seat of the soul. At first all will be dark and comfortless; but if thou persevere day and night, thou wilt feel an ineffable joy; and no sooner has the soul discovered the place of the heart than it is involved in a mystic and ethereal light." About the year 1337 this Hesychasm, the affinity of which with certain well-known forms of Oriental mysticism is obvious, attracted the attention of the learned and versatile Barlaam, a Calabrian monk, who at that time held the office of abbot in the Basilian monastery of St Saviour's in Constantinople, and who had visited the fraternities of Mount Athos on a tour of inspection. Amid much that he disapproved, what he specially took exception to as heretical and blasphemous was the doctrine entertained as to the nature of this divine light, the fruition of which was the supposed reward of Hesychastic contemplation. It was maintained to be the pure and perfect essence of God Himself, that eternal light which had been manifested to the disciples on Mount Tabor at the transfiguration. This Barlaam held to be polytheistic, inasmuch as it postulated two eternal substances, a visible and an invisible God. On the Hesychastic side the controversy was taken up by Gregory Palamas, afterwards archbishop of Thessalonica, who laboured to establish a distinction between eternal *οὐσία* and eternal *ἐνέργεια*. In 1341 the dispute came before a synod held at Constantinople; the decision, which no doubt was to a large extent determined by the excessive veneration in which the writings of the pseudo-Dionysius were held in the Eastern Church, was adverse to Barlaam, who in consequence returned to Calabria, and afterwards became bishop of Hierace in the Latin communion. Three other synods in relation to the same subject were subsequently held; and at the last of these, held in 1351 under the presidency of the emperor John Cantacuzenus, the uncreated light of Mount Tabor was established as an article of faith for the Greeks, who ever since have been ready to recognize it as an additional ground of separation from the Roman Church. The contemporary historians Cantacuzenus and Nicephorus Gregoras have both dealt very copiously with this subject, which is also more or less discussed in all the church histories. See Engelhardt's article on the Arsenians and Hesychasts in Illgen's *Zeitschr. f. Hist. Theol.*, viii. 48, and the account of the Hesychasts in Herzog's *Encyklopädie*. It may be mentioned that in the time of Justinian the word Hesychast was applied to monks in general simply as descriptive of the quiet and contemplative character of their pursuits.

HESYCHIUS was a grammarian of Alexandria, as we learn from a letter prefixed to his great work. From the fact that he was apparently unknown to Hesychius the Milesian and other writers of the time of Justinian, M. Schmidt considers that he must have flourished later than 530 A.D. On the other hand he cannot have been later than 642 A.D., when the school of Alexandria was scattered by the Saracen conquest. Many bad Greek words occur-

ring in his book show that he belonged to this late period. Welcker (*Rh. Mus.*, ii. 269) places him in the latter part of the 4th century. Belonging to the school of Alexandria, he was probably a pagan; and the explanations of words from Gregory Nazianzen and other Christian writers (*glossæ sacre*) are interpolations of a later time. He has left a Greek dictionary, containing a copious list of peculiar words, forms, and phrases, with an explanation of their meaning, and often with a reference to the author who used them or to the district of Greece where they were current. Hence the book is of great value to the student of the Greek dialects; while in the restoration of the text of the classical authors generally, and particularly of such writers as Æschylus and Theocritus, who used many unusual words, its value can hardly be exaggerated. The explanations given of many epithets and phrases reveal to us numberless facts about religion and social life, which are of the highest importance in the study of antiquities. In a prefatory letter addressed to his friend Eudocius (who is probably the Eudocius Scholasticus mentioned in the *Etymologicum Magnum* and elsewhere), Hesychius mentions that his work is based on the lexicon of Diogenianus, but that he has also used similar works by Aristarchus, Apion, Heliodorus, &c. (about whom see M. Schmidt's edition, vol. iv.). The text is very corrupt, and the order of the words has often been disturbed. There is no doubt that many interpolations, besides the Christian glosses, have been made.

HETTSTÄDT, or **HETTSTEDT**, a town of Prussian Saxony, in the circle of Mansfeld, and the government district of Merseburg, is situated on both banks of the Wipper, about 23 miles N.W. of Halle. It is the seat of a commission of justice, and has manufactures of machinery, pianofortes, and artificial manure. The population in 1875 was 5988. In the neighbourhood are mines of argentiferous copper, and the surrounding district and villages are occupied with smelting and similar works. Silver and sulphuric acid are the other chief products; nickel and gold are also found in small quantities. Hettstädt is mentioned as early as 1046; in 1220 it possessed a castle; and in 1380 it received the privileges of a town. When the countship of Mansfeld was sequestered, Hettstädt came into the possession of the Saxons, from whom it passed to the Prussians in 1815.

HEUGLIN, **THEODOR VON** (1824-1876), an eminent African and Arctic traveller, was born 20th March 1824 at Hirschlanden near Leonberg in Württemberg, and died at Stuttgart, 5th November 1876. His father was a Protestant pastor, and he was originally trained to be a mining engineer, but his own early ambition was to contribute to scientific progress by his personal explorations, and he prepared himself for his task by careful and multifarious discipline, studying the natural sciences, and more particularly zoology, acquiring the more serviceable of the modern languages, strengthening his physique by gymnastic exercises, and learning to use with equal skill his pencil and his gun. Supplied with funds by his mother's liberality, Heuglin went to Egypt in 1851, and till 1865 the north-eastern regions of Africa were the main scene of his labours. In 1852 he accompanied Dr Reitz, the Austrian consul at Khartum, in his fatal journey to Abyssinia; in 1853, having been appointed Dr Reitz's successor in the consulate, he visited Kordofan and the lower course of the White Nile; and in 1857, on his return after about two years' absence in Europe, he was commissioned by the grand-duke Ferdinand Maximilian of Austria to explore the countries along the west coast of the Red Sea. From the latter part of 1858 to the latter part of 1860 he was again in Europe; but in 1861 he was placed at the head of the Vogel search expedition, which included Munzinger,

Stuedner, Kinzellbach, &c., and was expected to make its way to Wadai. Having reached Mai-schecha, however, the explorers broke up into three parties, Heuglin turning along with Stuedner and Schubert in the direction of Adoa, Gondar, and the Galla lands. At Khartum they joined Miss Tinne's party, and proceeded to Lake Rey and the Kosanga river, but Stuedner died on 10th April 1863, and Heuglin was compelled by sickness to retrace his steps. He returned to Europe in 1865. In 1870 and 1871 he made a valuable series of explorations in Spitzbergen and Novaya Zemlya; but 1875 found him again in North-East Africa, in the country of the Beni Amer and Habab. An invitation from the khedive took him abroad again in 1876, but receiving no definite appointment he returned to Europe. Later in the same year he was engaged in preparing for an exploration of the island of Socotra, when he was suddenly carried off by inflammation of the lungs. He was buried beside Mauch, the African traveller, and a statue has been erected over his grave.

His principal works are *Systematische Uebersicht der Vögel Nordost-Afrika's*, 1855; *Reisen in Nordost-Afrika*, 1852-1853 (Gotba, 1857); *Syst. Uebersicht der Säugethiere Nordost-Afrika's* (Vienna, 1867); *Reise nach Abessinien, den Galla-Ländern, &c.*, 1861-62 (Jena, 1868); *Reise in das Gebiet des Weissen Nil*, 1862-1864 (Leipzig, 1869); *Reisen nach dem Nordpolarmeer*, 1870-71 (Brunswick, 1872-74); *Ornithologie von Nordost-Afrika's* (Cassel, 1869-75); *Reise in Nordost-Afrika* (Brunswick, 1877, 2 vols.). It is principally by his zoological, and more especially his ornithological, labours that Heuglin has taken rank as an independent authority. A list of the more important of his numerous contributions to Petermann's *Mittheilungen* will be found in that serial for 1877 at the close of the neurological notice.

HEUSCH, **WILLEM** or **GULLIAM DE**, a landscape painter in the 17th century at Utrecht. The dates of this artist's birth and death are unknown. Nothing certain is recorded of him except that he presided over the guild of Utrecht, whilst Cornelis Poelenburg, Jan Both, and Jan Weenix formed the council of that body, in 1649. According to the majority of historians, Heusch was born in 1638, and was taught by Jan Both. But each of these statements seems open to doubt; and although it is obvious that the style of Heusch is identical with that of Both, it may be that the two masters during their travels in Italy fell under the influence of Claude Lorraine, whose "Areadian" art they imitated. Heusch certainly painted the same effects of evening in wide expanses of country varied by rock formations and lofty thin-leaved arborescence as Both. There is little to distinguish one master from the other, except that of the two Both is perhaps the more delicate colourist. The guild of Utrecht in the middle of the 17th century was composed of artists who clung faithfully to each other. Poelenburg, who painted figures for Jan Both, did the same duty for Heusch. Sometimes Heusch sketched landscapes for the battlepieces of Molaer. The most important examples of Heusch are in the galleries of the Hague and Rotterdam, in the Belvedere at Vienna, the Städel at Frankfurt, and the Louvre. His pictures are signed with the full name, beginning with a monogram combining a G (for Gulliam), D, and H. Heusch's etchings, of which thirteen are known, are also in the character of those of Both. After Gulliam there also flourished at Utrecht his nephew, Jacob de Heusch, who signs like his uncle, substituting an initial J for the initial G. He was born at Utrecht in 1657, learnt drawing from his uncle, and travelled early to Rome, where he acquired friends and patrons for whom he executed pictures after his return. He settled for a time at Berlin, but finally retired to Utrecht, where he died in 1701. Jac. was an "Areadian," like his relative, and an imitator of Both, and he chiefly painted Italian harbour views. But his pictures are now scarce. Two of his canvases, the Ponte Rotto at Rome, in the Brunswick Gallery, and a lake harbour with

shipping in the Lichtenstein collection at Vienna, are dated 1696. A harbour with a tower and distant mountains, in the Belvedere at Vienna, was executed in 1699. Other examples may be found in English private galleries, in the Hermitage of St Petersburg, and the museums of Rouen and Montpellier.

HEVELIUS, HEVEL, HEWEL, HEWELKE, or HÖVELKE, JOHANN (1611–1687), astronomer, was born at Dantzic on January 28, 1611, and died there on January 28, 1687 (see *ASTRONOMY*, vol. ii. p. 754).

HEXHAM, a market-town of England, county of Northumberland, is situated on the south bank of the river Tyne, crossed there by a handsome stone bridge of nine arches, 20 miles west from Newcastle and 36 east from Carlisle, and on the line of railway connecting those towns. It is somewhat irregularly built, and consists chiefly of several narrow streets diverging from the market-place, a spacious square. Its defects in architecture and arrangement are, however, compensated for by its pleasant situation and the imposing remains of the old priory church. This church, begun by Wilfrid in 674, and completed by Acca, his successor, remained uninjured till 875, when every part of the monastery but the stone work was destroyed by the Danes. It was built of stones used in an earlier work, and many of them bear Roman inscriptions. Originally in dimensions and splendour it was unsurpassed on this side of the Alps, and doubtless had no small influence on ecclesiastical architecture in various parts of England. The building as renovated in the 12th century consisted of nave and transepts, choir and aisles, and a massive central tower; but the nave was burned by the Scots in 1296, and has never been rebuilt. The style is Early English with Transition details. The crypt, discovered in 1726, is a fine example of Saxon architecture, of which there appear also to be some traces in the choir. Among the interesting old monuments which have been collected in the transept is a sculptured stone slab of Oswulf, king of Northumbria, of the date 788. To the west of the church there are still some remains of the conventual buildings. Near the market-place there are two old castellated towers. A vessel containing about 8000 Saxon coins was discovered in the churchyard in 1832. The "Seal," formerly the park of the monks, is now used as a promenade, and from an eminence within its bounds a fine view is obtained. Hexham possesses a new town-hall and corn exchange, erected in 1866 in the Italian style, and a large board school. A hydropathic establishment has recently been opened. Leather gloves are the principal manufacture of the town; and it has tanneries, wool-staplers' yards, a brewery, and an iron and brass foundry. In the neighbourhood there are extensive market gardens and nurseries. The population of the township in 1871 was 5331, and of the parish 6437.

Hexham is supposed by some to have been the Axeldunum of the Romans, but although in all probability it was a Roman station, the similarity in the names is too slight to establish the identity. By the Saxons it was called Hextoldesham and Halgulstad from two of the neighbouring streams. Wilfrid, who founded the monastery and church in 673, received from Queen Etheldreda a grant of the town and a large surrounding tract of country. In 681 the southern portion of Bernicia was formed into the diocese of Hexham, which comprised the county of Durham and the greater part of Northumberland. In 821 Hexham was united to the diocese of Lindisfarne, after which it formed part of Durham, then of York until 1837, when it was restored to Durham. In 875 the town was plundered by the Danes and the monastery destroyed. In 1138 the monastery was plundered by the Scots, and in 1296 they again attacked the town and destroyed the nave of the conventual church. In the reign of Henry VIII. the last prior of Hexham was in 1536 hanged at the gate of the monastery for being concerned in the insurrection called the Pilgrimage of Grace.

Hexham, its Chroniclers, Endowments, and Annals, edited for the Surtees Society by James Raine, 1864–65; Hewitt, *A Handbook to Hexham and its Antiquities*, Hexham, 1879.

HEYDEN, JAN VAN DER, was born at Gorcum in 1637, and died at Amsterdam on the 12th of September 1712. He was an architectural landscape painter, a contemporary of Hobbema and Jacob Ruysdael, with the advantage, which they lacked, of a certain professional versatility; for, whilst they painted admirable pictures and starved, he varied the practice of art with the study of mechanics, improved the fire engine, and died superintendent of the lighting and director of the firemen's company at Amsterdam. Till 1672 he painted in partnership with Adrian van der Velde. After Adrian's death, and probably because of the loss which that event entailed upon him, he accepted the offices to which allusion has just been made. At no period of artistic activity had the system of division of labour been more fully or more constantly applied to art than it was in Holland towards the close of the 17th century. Van der Heyden, who was perfect as an architectural draughtsman in so far as he painted the outside of buildings and thoroughly mastered linear perspective, seldom turned his hand to the delineation of anything but brick houses and churches in streets and squares, or rows along canals, or "moated granges," common in his native country. He was a travelled man, had seen the Hague, Ghent, and Brussels, and had ascended the Rhine past Xanten to Cologne, where he copied over and over again the tower and crane of the great cathedral. But he cared nothing for hill or vale, or stream or wood. He could reproduce the rows of bricks in a square of Dutch houses sparkling in the sun, or stunted trees and lines of dwellings varied by steeples, all in light or thrown into passing shadow by moving cloud. He had the art of painting microscopically without loss of breadth or keeping. But he could draw neither man nor beast, nor ships nor carts; and this was his disadvantage. His good genius under these circumstances was Adrian van der Velde, who enlivened his compositions with spirited figures; and the joint labour of both is a delicate, minute, transparent work, radiant with glow and atmosphere, and most pleasant to look at. Almost all Van der Heyden's pieces are inscribed with his name alone, as if Van der Velde had been but a sleeping partner in his work. Like Heusch, he formed the first letters of his name into a monogrammatic interlacement. Very few of his pictures are dated. One, a street in a Dutch town, of 1666, is in the Hope collection in London. Two of 1667, a bridge on a canal, lined with houses casting their reflexions into the water, and the town-house at Amsterdam, are in the galleries of the Hague and Florence. Another view of the dam and town-hall at Amsterdam, dated 1668, is in the Louvre. A church and houses in the museum of Dresden is inscribed 1673. In all there are seventy or more of Van der Heyden's works fairly accessible to the public—those which are least so being chiefly in English private collections. Eight capital examples are in the Hermitage at St Petersburg, two of which are views in Cologne. Four are in the London National Gallery, four at Amsterdam and Dresden. Munich and Cassel have two apiece, and two very fine ones are in Buckingham Palace. The rest are in public and private galleries in Vienna, Paris, Frankfurt, and Carlsruhe.

HEYDUKE. See HAJDUK.

HEYLIN, PETER (1599–1662), an historical and polemical writer, born at Burford, Oxfordshire, 29th November 1599, was the second son of Henry Heylin, gentleman, who belonged to an old Montgomeryshire family. Being of a studious turn of mind, Heylin was entered at Hart Hall, Oxford, in 1613; was of Magdalen College, 1615; B.A., July 1617; M.A., 1620; B.D., 1629; D.D., 1633. In July

1618 he began to read college lectures on cosmography (*i.e.*, geography) with such acceptance that his associates made him fellow of Magdalen. The lectures, under the title of *Microcosmos*, were published in 1621; and many editions of this useful book, each somewhat enlarged, subsequently appeared, until scarcely any scholar's library was without a copy. In 1625 he published his observations on a journey to France. This book—which was frequently reprinted—Southey termed “one of our liveliest books of travel in its lighter parts, and one of the wisest and most replete with information that was ever written by a young man.” After obtaining the patronage of Laud, whose life he wrote, Heylin was made chaplain to Charles I. His legendary and learned *History of St George of Cappadocia* procured for him the rectory of Hemmingford, Hunts; his hearty attachment to the High-Anglican party brought many other preferments; and his analysis of Prynne's *Histriomastix* was rewarded by the rectory of Islip. He was also made a prebendary of Westminster (9th November 1631), treasurer to the chapter (1637), and subsequently sub-dean. Here he was the bitter opponent of the rule of Bishop Williams, the commendatory dean. With great ardour Heylin entered into the religious controversies which preceded the war, being equally hostile to the Puritan element within and without the church. He was consequently singled out for punishment by the committees of the Long Parliament, who deprived him of benefices worth £800, and heavily fined him. An amusing anecdote he tells affords proof of his unpopularity in London, and at the same time shows how his *Cosmography* was appreciated. As he passed along the street a fellow “shouldered” him with the remark, “Geography is better than Divinity.” For seven years, he says, his name was in almost every libel. He retired to his Hampshire parsonage of Alresford until Waller's army disturbed him. Robbed there of his library, valued at £1000, and his property, he went to Oxford, where from 1st June 1643 he edited *Mercurius Aulicus*, a vivacious but virulent news-sheet which greatly annoyed the Parliamentarians. His *Extraneus Vapulans*, written against L'Estrange (who wittily retorted that a prelate should be “no striker”), refers to his sufferings and hardships. The necessary quiet for his literary pursuits was ultimately found at Lacy's Court, Abingdon, whence were dated several books and pamphlets against those of his own communion whose opinions were not as unyielding as his, as also against the Presbyterians and others, controversies in which Ussher, Fuller, Baxter, and Harrington were concerned. His works, all more or less marred by political or theological rancour, were upwards of fifty in number; and they comprise histories of Episcopacy, of the Reformation, and of the Presbyterians, with a useful *Help to English History*. Some verses of merit also came from his active pen; and his poetical memorial of Bishop Waynflete was published by the Caxton Society in 1851. Heylin was a diligent writer and investigator, a good ecclesiastical lawyer, and had his learning always at command. His principles, to which he was honestly attached, were defended with ability; but his efforts to uphold the church passed unrecognized at the Restoration. His sight began to fail him; yet he rejoiced that his “old bad eyes” had seen the king's return. Upon that event he preached a jubilant sermon in Westminster Abbey to a great audience, 29th May 1661. He died on 8th May in the following year, and was buried two days after under his sub-dean's seat.

Lives of Heylin were written by Dr John Barnard, his son-in-law, and by George Vernon. Barnard's work was very carefully reprinted, with notes, in the *History of the Reformation*, published, 1849, by the Ecclesiastical History Society.

HEYNE, CHRISTIAN GOTTLÖB (1729–1812), one of the most distinguished critics and archæologists of the modern

school of which Ernesti and Gesner were the founders, was born on the 25th of September 1729, in a suburb of the city of Chemnitz in Saxony, where his father, who had been compelled by some religious persecutions to abandon his native country of Silesia, earned a precarious support for his family by exercising the trade of a weaver. It was only by the liberality of his godfathers that Heyne was enabled to obtain his primary instruction in the elementary school of Chemnitz, and afterwards to prosecute his classical studies in the gymnasium of that city. In 1748 he entered the university of Leipsic, with the professed intention of studying for the legal profession. There he was so scantily supported by those on whose assistance he relied that he was frequently in want even of the common necessaries of life, and was sometimes indebted for food to the generosity of a maid-servant in the house where he lodged. In this situation, without even the hope of future distinction, he continued to struggle on against every difficulty and disappointment in the acquisition of knowledge. For six months he is said to have allowed only two nights in the week to sleep, and he was at the same time forced to endure his godfather's reproaches for negligence in the prosecution of his studies. His distress had almost amounted to despair, when he procured the situation of tutor in the family of a French merchant resident in Leipsic. He was thus enabled to continue his studies, though with much interruption,—the emoluments of his appointment being sufficient to support him, in what was at least comparative comfort. Under Ernesti he was initiated into the criticism of the classical authors; from the prelections of the celebrated Bach he acquired a competent knowledge of Roman jurisprudence; and by Christius, who lectured on archæology, his attention was strongly directed to the works of ancient art. Even after he had finished his studies at the university, he was exposed for many years to all the accumulated distresses of poverty and neglect. The first situation he was able to procure was that of copyist in the library of Count von Brühl in Dresden, with a salary of somewhat less than twenty pounds sterling, which he obtained in the year 1753. From the necessity of adding something to this scanty pittance, he was forced to employ himself in the drudgery of translation; and, besides some French novels, he rendered into German the Greek romance of Chariton. He published his first edition of *Tibullus* in 1755, and in 1756 his *Epicetetus*. In the latter year the Seven Years' War broke out; Dresden was entered, and the Saxon archives seized; the Brühl ministry fell, and Heyne was once more in a state of absolute destitution. In 1757 he was offered a tutorship in the household of Frau von Schönberg, and there he first became acquainted with Teresa Weiss, whom he subsequently married. In January 1759 he accompanied his pupil to the university of Wittenberg, at which more than a year was spent in the study of philosophy and German history, but from which he was driven in 1760 by the Prussian cannon. The bombardment of Dresden (to which city he had meanwhile returned) on July 18, 1760; destroyed not only his humble lodging but also all his worldly possessions, which included amongst other valuable papers an almost finished edition of Lucian based on a valuable codex of the Dresden Library. In the summer of 1761 he married, although still without any fixed means of support; and for some time he found it necessary wholly to suspend his literary pursuits that he might devote himself to the duties of the office of land-steward, to which he had been charitably appointed in the household of the Baron von Lüben in Lusatia. He was enabled, however, to return to Dresden in the end of 1763, where he was commissioned by Lippert to prepare the Latin text of the third volume of his *Dactylotheca*. At length, in the commencement of the year 1763, Heyne's

merit met with its reward, and a new and illustrious career was opened to him. On the death of Johann Matthias Gesner at Göttingen in 1761, the appointment to the vacant chair had been first offered to Ernesti, who, however, declined leaving the university of Leipsic, but proposed Ruhnken of Leyden or Saxe of Utrecht for the appointment. Ruhnken likewise refused it, but having been strongly impressed with the taste and learning displayed by the editor of Tibullus and Epictetus, he advised Münchhausen, the Hanoverian minister and principal curator of the university of Göttingen, to bestow the professorship on Heyne, whose merit, though known to few, he was confident would do honour to the choice. The minister had the good sense to acquiesce in the recommendation of this great scholar, and Heyne, after some delay, became professor of eloquence in Göttingen. Though his appointments were at first few and his emoluments inconsiderable, these were gradually augmented in proportion as his usefulness was proved, and his growing celebrity rendered it an object with the other Governments of Germany to secure the services of so distinguished a scholar. He refused the most advantageous and honourable overtures from Cassel, Berlin, and Dresden. As professor, principal librarian, member of the Royal Society, and chief editor of the *Gelehrte Anzeigen*, and still more by his publications, he greatly contributed to raise the university of Göttingen to the distinguished rank it still holds among the seminaries of Europe. After a long and useful career, graced with all the distinctions which in Germany are conferred on literary eminence, he died, full of years and honour, on the 14th of July 1812.

Besides Tibullus (1755; 4th ed. by Wunderlich in 1817) and the *Enchiridion* of Epictetus (1756; 2d ed. 1776), he edited Virgil (1767-75; new ed. by Wagner, 1830-44), Pindar (1773; 3d ed. 1817), the *Bibliotheca Græca* of Apollodorus (1782; 2d ed. 1803), and the *Iliad* (1802),—all illustrated with copious commentaries. His *Opuscula Academica*, in six vols. (1785-1812), contain a series of more than a hundred academical dissertations, of which the most valuable are those respecting the colonies of Greece and the antiquities of Etruscan art and history. He left also a great number of papers on almost every subject of erudition, more especially on ancient mythology, among the *Commentationes Societatis Regiæ Göttingensis*. His *Antiquarische Aufsätze*, in two vols., comprise a valuable collection of essays connected with the history of ancient art. His contributions to the *Göttinger Gelehrte Anzeigen* are said by Heeren to have been between 7000 and 8000 in number. In the earlier part of his life he translated, or rather wrote anew, a great part of the *Universal History*. See Heeren, *Heyne's Biographie* (1813), which forms the basis of the interesting essay by Carlyle, originally published in the *Foreign Review* (1828), and now reprinted in his *Miscellanies*, vol. ii.

HEYWOOD, a manufacturing town of Lancashire, is situated on the Roch, and on the Lancashire and Yorkshire Railway, 3 miles east of Bury and the same distance southwest of Rochdale. It possesses several handsome churches and chapels, among which may be mentioned St Luke's church, erected in 1860, with a tall spire and a peal of bells. The other principal buildings are the national school, the mechanics' institute, the new Conservative club-house, and the market-hall. A new park—the Queen's Park—purchased and laid out at the cost of £11,000 with money which devolved to Her Majesty in right of her duchy and county palatine of Lancaster, was publicly opened on the 2d of August 1879. Heywood Hall in the neighbourhood of the town was at one time the residence of Peter Heywood, who contributed to the discovery of the Gunpowder Plot. Heywood owes its rise to the enterprise of the Peels, its first manufactures having been introduced by the father of the first Sir Robert Peel. It is an important seat of the cotton manufacture, in connexion with which it has upwards of fifty factories, and there are in addition power-loom factories, iron foundries, boiler-works, and railway waggon works. Coal is wrought extensively in the neighbourhood. The population in 1871 was 21,248.

HEYWOOD, JOHN (c. 1500-1565), sometimes styled "the Epigrammatist," was born, it is not known in what year, at North Mims near St Albans. He was educated at Oxford, and afterwards made the acquaintance of Sir Thomas More, who introduced him at court. His skill in music and his inexhaustible fund of ready wit made him a special favourite of Henry VIII., and afterwards of his daughter Mary. On the accession of Elizabeth, Heywood, who was a zealous Catholic, retired to Malines in Belgium, where he died in 1565. A collection of his works was published in 1562.

His longest single composition is the allegorical work, written in the octave stanza, entitled *The Spider and the Fly* (1556), in which the flies are the Roman Catholics and the spiders the Protestants, while Queen Mary is represented by the housemaid with her broom (the sword), executing the commands of her master (Christ) and her mistress (the church). It has been justly characterized by Warton as dull, tedious, and trifling. Of greater literary interest are the Interludes (*A Play between Johan the Husband, Tyb the Wife, and Sir Johan the Priest; A merry Play between the Pardoner and the Friar, the Curate and Neighbour Prat; The play called the four P's, a new and very merry Interlude of a Palmer, a Pardoner, a Polycur, and a Pedlar; A Play of Gentelness and Nobility; A Play of Love; A Play of the Weather*) which form a connecting link between the old moralities and the modern drama, and were extremely popular in their day. They generally represent some ludicrous incident of a homely kind in a style of the broadest farce, but in their way display considerable skill and talent. Other works of Heywood are a comic poem in long verse entitled *A Dialogue containing in effect the number of all the Proverbs in the English tongue compact in a matter concerning two marriages*; and three collections of Epigrams.

HEYWOOD, THOMAS, a voluminous dramatist and miscellaneous author of the 16th and 17th centuries, was born in Lincolnshire and was educated at Cambridge, where he became a fellow of Peterhouse. The dates of his birth and death are alike unknown, and the few facts of his life that are preserved have been gleaned chiefly from his own writings. He is mentioned in the MS. book of Henslowe as having written a book or play for the Lord Admiral's Company in October 1596; and from the same source we learn that in 1598 he was regularly engaged as a player and a sharer in that company. In the preface to *The English Traveller*, written in 1633, he describes himself as having had "an entire hand or at least a main-finger in two hundred and twenty plays." Of this number, which probably afterwards was considerably exceeded (for we find him still writing in 1640, and indeed his last published piece did not appear until 1655), only three and twenty survive; but they amply attest that had he chosen to concentrate his powers, he might easily have ranked with the Massingers, Fords, and others of his great contemporaries. "Heywood," says Charles Lamb, "is a sort of prose Shakespeare; his scenes are to the full as natural and affecting." His facility and variety are almost without a parallel, his fancy was inexhaustible, and his invention never at a loss; but he delighted to excess in what he called "merry accidents, intermixed with apt and witty jests," or in other words, in the broadest and coarsest farce. His best pieces, such as *A Woman Killed with Kindness*, *Fortune by Land and Sea*, *The English Traveller*, and *The Fair Maid of the West*, lie chiefly in the department of what has been called the domestic drama.

Besides his dramatic works, which were partly reprinted by the "Shakespeare Society," and were published in a complete edition of six vols. with notes and illustrations in 1874, he was the author of *Troia Britannica or Great Britain's Troy* (1609), a poem in seventeen cantos "intermixed with many pleasant poetical tales" and "concluding with an universal chronicle from the creation until the present time;" *An Apology for Actors, containing three brief treatises* (1612); *Γυναίκεϊον or nine books of various history concerning women* (1624); *England's Elizabeth, her Life and Troubles during her minority from the Cradle to the Crown* (1631); *The Hierarchy of the Blessed Angels* (1635); *Pleasant Dialogues and Dramas selected out of Lucian, &c.* (1637); and *The Life of Merten surnamed Ambrosius* (1641).

HEZEKIAH (הֶזְקִיָּא, הֶזְקִיָּה, הֶזְקִיָּהוּ or הֶזְקִיָּהוּ "Jehovah makes strong"; Ἐζεκίας; *Ezechias*; the *Ha-za-ki-ya-hu* or *Ha-za-ki-a-hu* of the Assyrian inscriptions), one of the greatest and best of the kings of Judah, succeeded his father Ahaz when still a young man (at the age of twenty-five according to 2 Kings xviii. 2; and this is probably correct if the LXX. be followed in reading "twenty-five" instead of "twenty" in 2 Chr. xxviii. 1; cf. 2 Kings xvi. 2). The year of his accession was most probably 717 B.C.;¹ and he ruled for twenty-nine years with a vigour and a success that deeply impressed later historians; "he trusted in the Lord God of Israel; so that after him was none like him among all the kings of Judah, nor any that were before him" (3 Kings xviii. 5; cf. *Ecclus.* xlviii. 17-25). The very outset of his reign was marked by an emphatic reversal, both in foreign and in domestic affairs, of the policy which had been so disastrously followed by his weak and foolish predecessor. While Ahaz had shown distinctly paganizing tendencies in religion, Hezekiah was ardent in his zeal for the exclusive worship of Jehovah, which he sought to simplify, centralize, and refine even at the expense of abolishing many cherished institutions which had the sanction of ancient usage. "He removed the high places, and brake the pillars, and cut down the Asherah, and brake in pieces the brazen serpent that Moses had made; for unto these days the children of Israel did burn incense to it; and he [or, perhaps, they] called it Nehushtan" (*i.e.*, according to the A.V., "brazen"); but, if this was the popular name, it is probably derived from *nahash*, serpent; see 2 Kings xviii. 4). How great were the strength of conviction and the courage which were necessary to such reforms as these is incidentally shown by the appeal to conservative feeling which some years afterwards could still be made by a skilful diplomatist with at least some hope of success (2 Kings xviii. 22). The details of the reforming activities of Hezekiah, extending even to the northern kingdom, as given with characteristic fulness and minuteness by the compiler of the book of Chronicles, are not now accepted by the majority of critics as absolutely trustworthy, a prevalent opinion being that actions have been attributed to Hezekiah which ought really to have been assigned to Josiah, and that some at least of the chronology is imaginary; but it is obvious that the influence of such prophets as Isaiah and Micah must have been powerful enough to bring about many thorough-going changes even during the earlier reign. As in the internal religious affairs of the theocratic kingdom so in its relations with foreign powers Hezekiah innovated very conspicuously on the policy of his father, although not here entirely on the lines laid down by the great contemporary prophet. Confirmed in the consciousness of military strength by a successful war against the Philistines (2 Kings xviii. 8), and having no longer anything to fear either from Damascus or from Samaria, he began to cherish the hope (at least with Egyptian support and the active co-operation of Egyptian cavalry) of being able to shake off entirely the yoke of Assyria, and with this view he set about extensive fortifications and other engineering works in and about Jerusalem. "He made

the pool and the conduit and brought the water into the city," "stopping the upper outlet of Gihon and bringing it straight by an underground way;" he also "built up all the wall that was broken, and raised thereupon towers" (2 Kings xx. 20; 2 Chr. xxxii. 5, 30; and cf. *Isa.* xxii. 8-11, which also has been referred by the sagacity of Ewald to this period). It is not clear from the sacred historians how far Judah was affected by the successful expedition of Sargon against Ashdod in 711 B.C., which is mentioned in *Isa.* xx. 1 (and in which possibly Sennacherib may have held the rank of a rabsaki or general); but Ewald's brilliant conjecture, to the effect that *Isa.* xxii. 1 *sqq.* alludes to hardships suffered by the people of Hezekiah at that time, is remarkably confirmed by the cuneiform inscriptions. It was not, however, until after the accession of Sennacherib (705) and the resolution of that monarch to direct one of his great expeditions against Egypt (c. 701), that matters were brought to a sharp and immediate crisis between Nineveh and Jerusalem. The capture of all his "fenced cities," Jerusalem excepted, coupled with the inactivity of Egypt, convinced Hezekiah of the uselessness of a struggle with the greatest military power of his century, in a way that Isaiah, with often repeated admonitions, had failed to do; and the payment of a large sum of money by way of tribute readily purchased a temporary relief. But when Sennacherib sent from Lachish his "tartan," or commander-in-chief, along with the "rab-saris," or head eunuch, and the "rab-shakeh," or chief of the staff (the rendering "chief cup-bearer" seems based on a wrong etymology), with a large force to demand the surrender of Jerusalem itself, it was felt by king and prophet alike that the time for resistance to the utmost had come. Probably the resolution thus formed was in part, at least, due to the fact that the main body of the Assyrian army was already finding it necessary to fall back before Tirhakah, the Ethiopian king of Egypt, from Lachish to Libnah; it was at all events justified, not only by the indecisive battle at Altaku near Ekron, but also by the pestilence (2 Kings xix. 35) which speedily compelled the withdrawal of Sennacherib with the remains of his army from Libnah to Nineveh. The relation between the accounts of this retreat given by Sennacherib himself, by the sacred historians, and by Herodotus (ii. 141) will be considered in the article SENNACHERIB. The sickness and recovery of Hezekiah, recorded in 2 Kings xx. 1-11 and (with additional details) in *Isa.* xxxviii., seem to have preceded the invasion of Sennacherib by three years at most; they were almost immediately followed by the arrival of the messengers of Merodach (not Berodach) Baladan, the son of Baladan, who for some six months, until repressed by Sennacherib, usurped the throne of Babylon about the year 703. The excessive courtesy shown to these ambassadors gave occasion, it is recorded (2 Kings xx. 17, 18), to a prediction by Isaiah of the Babylonian exile, which took place more than a century afterwards. Of the later portion of Hezekiah's reign no details have been preserved; but it appears to have been characterized by peace and prosperity. He was succeeded in 688 by Manasseh, his son by Hephzibah, born apparently about 702. Besides being a patron of literature (*Prov.* xxv. 1), Hezekiah was himself a poet; and his sole remaining production (*Isa.* xxxviii. 10-20), if somewhat deficient in originality, abounds in depth and tenderness of religious and poetic feeling.

HIBERNATION (frequently, but less correctly, written **HYBERNATION**) is the term employed by naturalists to denote the peculiar state of torpor in which many animals which inhabit cold or temperate climates pass the winter. In hot and dry countries, on the contrary, various animals pass into a similar condition during the hottest season of the year; and this state is called "Aestivation."—Several

¹ Hales and Ussher gave respectively 727 and 725 B.C.; and these dates were accepted as close approximations by all subsequent chronologists until the decipherment of the Assyrian inscriptions, when it became apparent that the destruction of Samaria by Sargon and the Egypto-Palestinian expedition of Sennacherib were separated by a wider interval than eight years, and therefore that 2 Kings xviii. 10 and 2 Kings xviii. 13 cannot both be right. In the present article the chronology of Schrader (art. "Sanherib," in Schenkel's *Bibel-Lexicon*, 1; comp. *Die Keilinschriften u. das Alte Testament*) is that which is substantially followed. A full exposition of the bearings of the cuneiform inscriptions on the chronology of the Bible must be postponed to the article on the history of Israel. See also **BABYLONIA**, vol. iii. p. 187.

of the animals which hibernate during the winter are liable to fall into a similar state at intervals during mild weather, and Dr Marshall Hall has applied the term "Diurnation" to the day-sleep of bats, which he regards as precisely analogous to hibernation.

MAMMALIA.—Although comparatively few mammals hibernate, the phenomena of hibernation and similar conditions have been better studied in this class than in any other. Dr Marshall Hall has laid down the principle that the amount of respiration is inversely as the degree of irritability of the muscular fibre. Every gradation may be met with between ordinary sleep, the imperfect or abnormal hibernation of some animals, and the profound hibernation of others, in which all the functions of life are almost suspended. Such a condition is always accompanied by reduced respiration, and increased irritability of the muscular fibre. If the respiration is reduced without this irritability being increased, death results from torpor and asphyxia, whereas, if the respiration is increased simultaneously with increased irritability (as when an animal is aroused too suddenly), death likewise results from too great stimulation of the vital powers. The well-known danger of suddenly awakening a patient from a state of somnambulism is doubtless due to a similar cause.

Hibernation, however, is a physiological condition, and not produced simply by cold, though it is favoured by it, because cold induces sleep, which may afterwards pass into hibernation. It is an error to suppose that hibernating animals are capable of resisting any amount of cold, though their capacity of doing so must vary according to their species and to the climate which they inhabit. They always seek secure hiding-places where they may be protected from too great a degree of cold, as well as from interference. During hibernation the temperature of their bodies sinks to a point corresponding nearly to that of the surrounding atmosphere; but if they are exposed to an unusual amount of cold, they are first awakened by it, and then sink into a fatal torpor like other animals. Many hibernating animals perish in this manner during severe winters.

Respiration being almost suspended during hibernation, the maintenance of vitality depends almost wholly on the action of the heart, which will continue for a long time after an hibernating animal has been decapitated. Animals may also be placed in carbonic acid or under water for several hours, without injury, when in this condition, though they would die in a very few minutes if they were in their normal state.

Man.—Long-continued suspension of consciousness in man, whether voluntary or otherwise, is rare in temperate climates, but it is more frequent in India, where some religious ascetics are stated on unimpeachable authority to possess the power of throwing themselves into a state closely resembling hibernation for an indefinite period. Many curious cases have been recorded by Mr Braid in his small treatise on *Human Hybernation*, published in 1850, the most celebrated of which is that of a fakir who was actually buried alive at Lahore, in 1837, in the presence of Runjeet Singh and Sir Claude Wade, and who was dug up and restored to consciousness several months afterwards, after every precaution had been taken to prevent any one from disturbing the grave in the interval.

Bats.—Dr Marshall Hall says that the hibernating bat never wakes at all, except from warmth or excitement, and that the digestive functions are suspended to a far greater degree than in the dormouse or hedgehog. Respiration is also suspended, and when the animal is disturbed it quickly subsides again into total quiescence, after a few feeble respirations. It is to be regretted that Dr Hall has not stated to which species of bat his remarks refer, as the

habits of the various species differ. Earlier or later in autumn, according to the species, they retire to caves, hollow trees, and similar hiding-places, where they cluster together, hanging head downwards by their hinder claws, and clinging to each other, as well as to the walls and sides of their retreat, so that a great number can crowd themselves into an amazingly small space. Although such assemblies frequently consist of more than one species, yet the various species do not all retire to their winter quarters at the same period; the noctule is rarely seen abroad later than July, whereas the pipistrelle may be seen flying on mild evenings almost every month in the year. It is only natural to suppose that the hibernation of the former species is much more profound than that of the latter, which doubtless feeds in winter as well as summer; for though insects are far less numerous in winter than in summer, yet some species appear only at that season of the year.

Bear and Badger.—These animals retire to winter quarters in northern climates, and pass the greater part of their time in sleep; but the brown bear and badger do not fall into a state of genuine hibernation. When the bear retires for the winter, he is very fat, and it is said that the black bear will not hibernate if this is not the case. Digestion is suspended, and his intestines become stopped up with an indigestible mass chiefly composed of pine leaves, which is not discharged till spring. The brown bear of Europe and Siberia is very dangerous if disturbed during the winter; but the black bear of America can scarcely be aroused from his torpor, which there is thus reason to believe is a state of true hibernation, differing from that in which the former species passes the winter.

Hedgehog.—This animal hibernates more completely than almost any other. In the autumn it retires to a hole among rocks or under the roots of a tree, where it remains for the winter, seldom or never awakening till spring, and of course taking no food until then. If a sleeping hedgehog is disturbed, it merely stirs, and then coils itself up more closely; but if a hibernating hedgehog is interfered with, it takes a deep sonorous inspiration, followed by a few feeble respirations, and then by total quiescence. The tenrec, an allied animal found in Madagascar, sleeps for three months in its burrow during the hottest period of the year.

Rodentia.—Several animals belonging to this order hibernate more or less completely, among which we may mention the hamster, the porcupine, the dormouse, the squirrel, and the marmot. Several of these awake at intervals to feed, and therefore lay up a store of provisions before they retire, although they all become very fat before winter. Other species of this order hibernate less perfectly, or only occasionally, like the hare which will lie beneath deep snow in a small cavity, just large enough to receive her body, for some weeks unharmed. But this is not true hibernation, as respiration is maintained during the whole time, a small air-hole being always kept open by the warm breath of the animal. In a similar manner sheep (though belonging to a very different order of animals) have sometimes been buried in snow-drifts in Scotland for several weeks without sustaining any injury. The dormouse not only hibernates in the strict sense of the term, but will sleep at intervals for several days together during mild weather. When a *Myoxus*, an allied animal inhabiting Africa, was brought to Europe, it hibernated as if this were its normal habit. Whether it aestivates in its native country is not known, but its hibernating in Europe shows a greater power of adapting itself to changed conditions of life than we should have been inclined to suspect.

AVES AND PISCES.—It was formerly supposed that various species of swallows hibernated, and it was even asserted that the sand martin was accustomed to bury itself

in the mud at the bottom of the water; but this has long been regarded as an exploded error. For the hibernation of fish, compare the article on ICHTHOLOGY.

AMPHIBIA AND REPTILIA.—All the animals belonging to these classes hibernate in cold or temperate climates. Land tortoises bury themselves in holes in the ground, and fresh-water tortoises in the banks or at the bottom of lakes and rivers. Lizards and snakes retire to holes in trees, under stones, or among dead leaves, where many species congregate in large numbers, and pass the winter closely entwined, and in a still more torpid condition than that of the hibernating mammals, their digestion and respiration being entirely suspended. Many tortoises, crocodiles, and serpents bury themselves in mud in both South America and Africa, and æstivate in the hard-baked ground during the dry season of the year. When the viper is disturbed during the winter its bite is harmless; but this is not the case with the venomous serpents which æstivate in tropical countries.

Frogs generally hibernate in masses in the mud at the bottom of the water, and if awakened from hibernation by warmth can remain eight times longer under water without drowning than frogs in the breeding season. We should hardly expect the habits of such an animal as the frog to be greatly affected by domestication, but Professor Bell was acquainted with a gentleman living at Kingston, whose kitchen was built on the banks of the Thames, and whose servants made a pet of a frog which had his hole in the skirting. It was unnecessary for the frog to hibernate, and instead of doing so he came out of his hole every evening to bask before the kitchen fire for three successive winters. It is impossible to say how long frogs and toads may continue to retain a dormant life, if the mud in which they bury themselves should become hardened around them during hibernation. Too many circumstantial accounts of the discovery of live toads embedded in solid rock, and even in coal, have been published to allow us to dismiss them all as fabulous, notwithstanding the difficulty and obscurity in which this subject is still involved.

MOLLUSCA.—Many species hibernate. The land-snails bury themselves in the ground, or conceal themselves under the back of trees, in holes in walls, or even in the stems of large umbelliferous plants. They close the mouth of the shell with a calcareous plate, technically called an epiphragm, which they secrete by means of their mantle, and which is perforated by a small hole to admit the air. In winter they bury themselves with the head upwards, and do not grow at all during the winter; but while growing they bury themselves in summer, with the head downwards, at occasional intervals, for several days together, and then grow very rapidly. Snails are not considered in season at Paris till after the first frost, when they are closed with a white epiphragm. In dry weather, and during the heat of summer, snails also close their shells with an epiphragm, to protect themselves from drought, but this covering is thinner than that which they construct during the winter. In the British Museum is preserved the shell of a specimen of *Helix desertorum*, from Egypt, which revived after having been gummed to a board for four years' in the Museum, and lived for two years afterwards. Other instances of the revival of land-shells after a still longer period are equally well authenticated. Some species

Helix Desertorum.

the ground, and become torpid during frosts or droughts, but it is doubtful whether their condition is that of genuine hibernation. The fresh-water mussels (*Anodonta*) hibernate before the close of autumn, and bury themselves in the mud till the beginning of spring. It is believed that many of the marine *Mollusca* also hibernate, but very little is known of their habits at present.

INSECTA.—Most of the insects which pass the winter as larvæ or perfect insects hibernate during the period that they can obtain no food. Larvæ which are full grown in autumn frequently lie dormant during the winter, and do not assume the pupa state till spring. In the case of insects which have more than one brood in the year, the last brood generally hibernates, sometimes retiring to winter quarters quite early in the autumn, while the perfect insects of the previous brood are still flying about, and while the weather is still fine and warm. Insects which hibernate in the perfect state do not pair till spring, and are probably not fully developed till after hibernation. Hive-bees probably do not hibernate, and it is well known that they require food during the winter. It is asserted that the aphides, on whose sweet secretion ants chiefly subsist in inclement weather, become torpid at exactly the same low temperature as the ants themselves.

CONCLUDING REMARKS.—The seeds of many plants, and the eggs of many of the lower forms of animal life, may remain dormant for years in cold or dry climates, until heat or moisture awakes them to vitality. Many plants die down in winter, the roots remaining in the ground, while many trees then shed their leaves, the sap retiring to the roots. Similar phenomena take place in tropical countries during the hot, dry season, wherever the amount of humidity in the atmosphere is insufficient to maintain a perennial vegetation during the year. These phenomena in the vegetable world are regarded as analogous to those of hibernation in animals, and the term "hibernation of plants" is sometimes applied to them.

HICKES, GEORGE (1642-1715), a learned English divine of the nonjuring party, and an eminent Anglo-Saxon scholar, was born at Newsham near Thirsk, Yorkshire, on June 20, 1642. In 1659 he entered St John's College, Oxford, whence after the Restoration he removed first to Magdalen College and subsequently to Magdalen Hall. In 1664 he was chosen fellow of Lincoln College, and in the following year proceeded M.A. On his return from a Continental tour in 1673 he graduated in divinity, and in 1675 he was appointed rector of St Ebbe's, Oxford; in the following year he as private chaplain accompanied the duke of Lauderdale, the royal commissioner, to Scotland; and shortly afterwards he received the degree of D.D. from the university of Glasgow. In 1680 he became vicar of All Hallows, Barking, London; and after having been made chaplain to the king in 1681, he was in 1683 promoted to the deanery of Worcester. At the revolution of 1688, having declined to take the oath of allegiance to William and Mary, he was first suspended and afterwards deprived,—he meanwhile affixing to the cathedral doors a "protestation and claim of right" that he was, and still did "continue to be, the only rightful and legal dean of this cathedral church of Worcester." After remaining some time in concealment in London, he was employed by Sancroft and the other nonjurors as a mission to the Continent on matters connected with the proposed action of his party relative to the continuance of their episcopal succession; upon his return he was himself consecrated by Lloyd, White, and

Turner suffragan bishop of Thetford in 1694. His later years were largely occupied in controversies the interest of which has now almost wholly passed away; but to them we owe the two works which constitute his chief claim to an enduring reputation, the learned *Institutiones Grammaticæ Anglo-Saxonicæ et Mæso-Gothicæ* (1689), and *Linguarum veterum Septentrionalium Thesaurus grammatico-criticus et archaeologicus* (1703–1705). In 1713 he united with Bishops Campbell and Gadderar to consecrate Jeremy Collier, Samuel Hawes, and Nathaniel Spinkes to be bishops in the nonjuring church. He died December 15, 1715.

Even apart from the two works already mentioned, Hickes was a very voluminous and laborious author. His earliest performances, which were anonymous, were suggested by contemporary events in Scotland that gave him great satisfaction,—the execution of Mitchel on a charge of having been implicated in the murder of Archbishop Sharp, and that of Kid and King, Presbyterian ministers, “for high treason and rebellion” (*Ravillac Redivivus*, 1678; *The Spirit of Popery speaking out of the Mouths of Phanatical Protestants*, 1680). In his *Jovian* (an answer to Johnson’s *Julian the Apostate*, 1683), he endeavoured to show that the Roman empire was not hereditary, and that the Christians under Julian had recognized the duty of passive obedience. His *Two Treatises*, one “On the Christian Priesthood” and the other “On the Dignity of the Episcopal Order,” originally published in 1707, have been more than once reprinted, and form three volumes of the *Library of Anglo-Catholic Theology* (1847). In 1705 and 1710 were published *Collections of Controversial Letters*, in 1711 a collection of *Sermons*, and in 1726 a volume of *Posthumous Discourses*. Other treatises, such as the *Apologetical Vindication of the Church of England*, are to be met with in Gibson’s *Preservative against Popery*.

HICKORY. The hickory trees are natives of North America, and belong to the genus *Carya* of botanists. They are closely allied to the walnuts (*Juglans*), the chief or at least one very obvious difference being that, whilst in *Carya* the husk which covers the shell of the nut separates into four valves, in *Juglans* it consists of but one piece, which bursts irregularly. The hickory trees are of lofty growth, and are held in high estimation, both on account of their durable timber, and from the excellent nuts which some of the species produce. The timber is both strong and heavy, and remarkable for its extreme elasticity, but it is not much used either for shipbuilding or for architectural purposes, as it decays rapidly when exposed to heat and moisture, and is peculiarly subject to the attacks of worms. It is very extensively employed in manufacturing musket stocks, axle-trees, screws, rake teeth, the bows of yokes, the wooden rings used on the rigging of vessels, chair backs, axe-handles, whip-handles, and other purposes requiring great strength and elasticity. Its principal use in America is for hoop-making; and when it is remembered how large a proportion of the productions of the United States is packed in barrels, some estimate may be formed of the consumption of hoops and of the consequent demand for hickory wood, which is the only American wood found perfectly fit for that purpose.

The wood of the hickory is of great value as fuel, on account of the brilliancy with which it burns and the ardent heat which it gives out, the charcoal being heavy, compact, and long-lived. The species which furnish the best wood are *Carya alba* (shell-bark hickory), *C. tomentosa* (mockernut), *C. olivæformis* (pecan or pacane nut), and *C. porcina* (pig-nut), that of the last-named, on account of its extreme tenacity, being preferred for axle-trees and axe-handles. The wood of *C. alba* splits very easily and is very elastic, so that it is much used for making whip-handles and baskets; the whip-handles are greatly esteemed for their suppleness, and considerable numbers of them are annually imported into England. The wood of this species is also used in the neighbourhood of New York and Philadelphia for making the back bows of Windsor chairs. The timber of *C. amara* and *C. aquatica* is considered to be of inferior quality.

Most of the hickories form fine-looking noble trees of from 60 to 90 feet in height, with straight, symmetrical

trunks, well-balanced ample heads, and bold, handsome pinnated foliage. When confined in the forest they shoot up 50 or 60 feet without branches, but when standing alone they expand into a fine head, and produce a lofty round-headed pyramid of foliage. They have, observes Downing, all the qualities which are necessary to constitute fine graceful park trees, and are justly entitled to a place in every considerable plantation. The most ornamental of the

FIG. 1.—Shell-bark Hickory (*Carya alba*) in flower ($\frac{1}{2}$ nat. size). 1, Female flower (nat. size); 2, portion of male inflorescence (nat. size).

species are *C. olivæformis*, *C. alba*, and *C. porcina*, the last two also producing delicious nuts, and being worthy of cultivation for their fruit alone.

The husk of the hickory nut, as already stated, breaks up into four equal valves or separates into four equal portions in the upper part, while the nut itself is tolerably even on the surface, but has four or more blunt angles in its transverse outline. The hickory nuts of the American markets are the produce of *C. alba*, which is called the

FIG. 2.—1, Fruit of *Carya alba*; 2, hickory nut; 3, cross section of nut; 4, vertical section of the seed. All natural size.

shell-bark hickory because of the roughness of its bark, which becomes loosened from the trunk in long scales bending outwards at the extremities and adhering only by the middle. The nuts are much esteemed in all parts of the States, and are exported in considerable quantities to Europe. The pecan-nuts, which come from the Western States, are from an inch to an inch and a half long, smooth, cylindrical, pointed at the ends, and thin-shelled, with the kernels full, not like those of most of the hickories divided by partitions, and of delicate and agreeable flavour. The thick-shelled fruits of the pig-nut are generally left on the ground for swine, squirrels, &c., to devour. In *C. amara* the kernel is so bitter that even the squirrels refuse to eat it.

HICKS, ELIAS (1748–1830), founder of the Hicksites, one of the two great sections into which the Society of Friends in America has since 1828 been divided (see **QUAKERS**), was born at Hempstead, Long Island, on March 19, 1748. During the earlier part of his life he followed the business of a carpenter and housebuilder; but this occupation he latterly exchanged for that of farming. Reared in a Quaker family, he began, when about twenty-seven years of age, to “have openings leading to the ministry,” and to be “deeply engaged for the right administration of discipline and order in the church.” In the intervals of business, accordingly, he began to visit the meetings and families of Friends throughout an extensive range of country; and soon he established a very considerable reputation as an efficient and popular itinerant preacher. His first literary effort seems to have been made no earlier than 1811, when he published *Observations on Slavery*; those doctrinal divergences from the received orthodox creed of the Friends, by which his name was brought into the prominence it now possesses, appear not to have become visible until 1820, when he wrote a *Doctrinal Epistle* (published in 1824), which was followed by much controversy, and resulted in 1828 in the formal separation from the Hicksites of their more orthodox Quaker brethren. The points involved were justly considered to affect the fundamental doctrines of the Christian religion, such as those of the Trinity, the Incarnation, and the supreme authority of Scripture. Hicks died at Jericho, Long Island, on February 27, 1830. See *Journal of the Life and Labours of Elias Hicks* (Philadelphia, 1828).

HIERAPOLIS. Of the many cities in the Greek world bearing this name the following are the most important.

1. A city of Syria Cyrrhestica, situated on some hills about 16 miles south-west from the junction of the Euphrates and the Sajur. Besides the natural strength of its position, it was important as lying on the line of intercourse between Northern Syria and Mesopotamia, and was always a great trading city. Its early history is quite unknown. It is not mentioned during the Assyrian wars in this part of Syria (see Sayce, *Academy*, October 1876). Abul Faráz asserts that Josiah was defeated there by Pharaoh Necho (611 B.C.) on his march towards Carchemish; but according to 2 Chron. xxxv. 20 the battle took place at Carchemish, which lay on the Euphrates a little further north on the site of the modern Jerablús, or Jerabis; and probably Abul Faráz confounded the two cities. The same confusion perhaps has caused the statement of Ammianus that Hierapolis was identical with Ninus Vetus on the Euphrates. Jerablús is clearly a corruption of Hierapolis, by which name therefore Carchemish must at some time have been styled by the Greeks; but it is surprising to find two great cities of the same name so near one another. No proof exists that Hierapolis was an important city before the time of the Seleucidæ, and Professor Sayce suggests that it then succeeded to the trade and name of the older city, which had now decayed. Its original name is given in Greek as Βαμβύκη, which points back to a form Bambyg or Mambog, while the Syrian form is given by Pliny as Mabog, i.e., Mabbog for Mambog. The romance of trade by which this name has become naturalized in many European languages deserves a passing notice. As the city lay on the highway to the East, cotton and silk were important branches of its trade. Probably cotton plantations existed there in old time; and after the cultivation of silk was introduced to western Asia in the time of the Sassanian kings, large groves of mulberry trees surrounded the city. The name Mambe was afterwards confounded with the Persian word pambe, silk; and the Greek form Βαμβύκη also was similarly mixed up with the

word βόμβυξ,¹ which originally denoted the fly supposed to spin on trees the cotton or silk (for the two substances were confused by the Greeks and Romans) which men then gathered off the trees (Virg., *Georg.*, ii. 121). Hence the “Bombycinæ vestes” of the Roman writers; while the city itself is called “Bombycina urbs.” In Asia cotton seems to have been known as a distinct article, and was named after the city which was the chief seat of its manufacture, as muslin is from Mosul. By the crusaders the stuff and the name were carried to Europe, and the latter exists in English in the form “bombazine.” The Syrian goddess Atargatis, called by the Greeks Derceto, a personification of the nature power worshipped under different names over the whole of western Asia, had one of her most famous temples in the city; and perhaps Mambe may have been a local name of the goddess. Hence in the 3d century B.C., when, under the Seleucid kings, Bambyco became a great Greek city and the most important station between Antioch and Seleucia, it was called Hierapolis or Hieropolis. The latter form is found on coins, the former is used in classical literature. The coinage of Hierapolis begins under the Seleucidæ. The autonomous coins, probably for commercial reasons, imitate closely the coins of Antioch. The temple was plundered by Crassus on his Parthian expedition (53 B.C.). Under Diocletian or Constantine, Hierapolis became the capital of the new province of Euphratensis, a name which soon gave place to the older name Commagene. As paganism decayed, Hierapolis ceased to be the sacred city, and recovered its ancient name; at the same time its importance and population declined. In the time of Julian, who concentrated there the Roman troops for the fatal Parthian campaign, it was still one of the greatest cities of Syria; but under Justinian, who made some attempt to restore it, great part of its area was a desert, and the once strong fortifications were so decayed that the place was not defensible against the Parthian king Chosroes. At the Arab conquest it passed into the hands of the caliphs. Haroun-al-Raschid (786–808) restored it and strengthened its walls, and it is mentioned about 1150 by Edrisi as a strong city. As the empire of the caliphs dwindled, Mambedj became a frontier post in the struggle between Christians and Mahometans, and its possession carried with it the rule in this part of Syria. The emperor Romanus Diogenes captured it in his gallant struggle against the Turks (1068). Recaptured by the Seljuk Turks, it soon afterwards fell into the power of the crusaders, until it was stormed by Saladin (1175). It was for some time the headquarters of the Mongol host under Hulagu Khan; and, as with many other Syrian cities, its desolation dates from this time. The ruins which still exist called Kara Bambucho or Buyuk Mambedj, have been described by Pococke and others, and most carefully by Chesney (*Euphrates Expedition*, i. 420).

Strabo (xvi. p. 748) confuses this Hierapolis with Edessa in Mesopotamia. A very full account of the city to supplement the brief outline here given may be found in Ritter, *Erkunde*, x. 1011–65.

2. A city in Phrygia, at the junction of the Lycus and Meander, on the road from Apanca to Sardis. In it there were warm springs which had and still have a remarkable power of forming incrustations. Its name Hierapolis is due to the sanctity conferred on it by these hot springs, and by the Plutonium, a small cave under a projecting rock, from which there constantly emanated a dark vapour deadly to man and beast (Strabo, xiii. 629; Vitruv., viii. 3; Apuleius, *De Mundo*, p. 65). In reference to this we find sometimes on its coins Pluto carrying off Proserpine.

¹ Βόμβυξ is borrowed from the Persian word (Benfey, *Wurzeltz.*, ii. 113), though the form it has taken in Greek is influenced by the word βουβίω, to buzz. It is used by Aristotle, &c., to denote a gnat found in Asia Minor, which has certainly nothing to do with silk.

The water was also much used for dyeing. Nothing is known of the origin of the city; from the legend ἀρχαγγέλως on coins, with a radiate head of the sun-god, Eckhel concludes that a Greek foundation was made under the guidance of Apollo; but a native city may have already existed there. The native name of the sun-god was Λαοβργος, which often occurs on coins; he was probably a Phrygian form of the Greek Zeus. The goddess of healthful drinking, Euposia, is also seen on coins. Cybele also, who is found on the coins, was one of the chief deities of the place. Little is known of the history of the city. The philosopher Epictetus was born there; and there St Paul founded a church (Coloss. iv. 13). The very considerable ruins which still exist, called Pambuk Kalessi ("Cotton Castle"), have been described by Pococke, Leake, &c. The ancient theatre and gymnasium are in a state of remarkable preservation.

HIERARCHY. From *ιεράρχης*, meaning a steward or guardian of holy things, is derived *ιεραρχία*, naturally signifying the office of such a steward or guardian (not a "ruler of priests" or "priestly ruler"; see Boeckh, *Corp. Inscr. Gr.*, No. 1570), but most commonly used in ecclesiastical language to denote the aggregate of those persons who exercise authority within the Christian Church,—the patriarchate, episcopate, or entire threefold order of the clergy. The word, which does not occur in any classical Greek writer, owes its present extensive currency to the celebrated writings of Dionysius Pseudo-Areopagita, which, originating probably in the age of Justinian, exerted during the 9th and following centuries so remarkable an influence on the current of theological speculation, both in the Eastern and in the Western Church. Of these the most important are the two which treat of the celestial and of the ecclesiastical hierarchy respectively. Defining hierarchy as the "function which comprises all sacred things," or, more fully, as "a sacred order and science and activity, assimilated as far as possible to the godlike, and elevated to the imitation of God proportionately to the Divine illuminations conceded to it," the author proceeds to enumerate the nine orders of the heavenly host, which are subdivided again into hierarchies or triads, in descending order, thus:—Seraphim, Cherubim, Thrones; Dominations, Virtues, Powers; Principalities, Archangels, Angels. These all exist for the common object of raising men through ascending stages of purification and illumination to perfection. The ecclesiastical or earthly hierarchy is the counterpart of the other. In it the first or highest triad is formed by baptism, communion, and chrism. The second triad consists of the three orders of the ministry, bishop or hierarch, priest, and minister or deacon (*ιεράρχης, ιερέυς, λειτουργός*); this is the earliest known instance in which the title hierarch is applied to a bishop. The third or lowest triad is made up of monks, "initiated," and catechumens. To Dionysius may be traced, through Thomas Aquinas and other Catholic writers of the intervening period, the definition of the term usually given by Roman Catholic writers—"cœtus seu ordo præsidum et sacrorum ministrorum ad regendam ecclesiam gignendamque in hominibus sanctitatem divinitus institutus"¹—although it immediately rests upon the authority of the sixth canon of the twenty-third session of the council of Trent, in which anathema is pronounced upon all who deny the existence within the Catholic Church of a hierarchy instituted by divine appointment, and consisting of bishops, priests, and ministers.² This definition, however, relates only to what is called the "hierarchy of orders," to which hierarchy, it must further

be borne in mind, belong the lesser orders of sub-deacon, acolyth, exorcist, lector, and doorkeeper (to which that of singer is sometimes added); though these are to be regarded as institutions of ecclesiastical authority only, while the other three are of divine right, and therefore pre-eminently "holy." The "hierarchy of jurisdiction," as distinguished from that of "orders," is represented by the Roman pontiff alone, who enjoys supreme authority over all bishops, even when these are assembled in general council. This supreme authority he holds by divine right as the successor of Peter, who received immediately from Christ the primacy of honour and of jurisdiction over the universal church.³ Between the pope and the bishops occur the metropolitans or archbishops and the patriarchs; but these intermediate grades are not regarded as essential, and, for the present at least, the rank of patriarch may almost be said to be, in the Roman communion, purely titular. The Greek Church, like the Roman, recognizes a threefold clerical order, distinct *jure divino* from other Christians, of bishops, priests, and deacons. The five patriarchs, of equal dignity, hold the highest rank in the episcopate; and the episcopal body united in a general council represents the church, and infallibly decides, under the guidance of the Holy Ghost, all matters of faith and ecclesiastical life. The Anglican Church acknowledges the superior and divinely conferred authority of the episcopal order, but, seeking its hierarchical doctrine in the records of a comparatively early period of church history, holds the substantial equality of all bishops, and, while acknowledging the validity, does not maintain the necessary infallibility, of their decisions when met in general council. Thus in form of government the Roman Church may be said to be a hierarchical monarchy, the Greek in some sense a patriarchal oligarchy, and the Anglican an episcopal aristocracy. For historical and other details relating to the growth and development of the hierarchical system the reader is referred to the articles APOSTLE, ARCHBISHOP, BISHOP, CARDINAL, CHURCH, CLERGY, COUNCIL, DIOCESE, EPISCOPACY, EXARCH, PATRIARCH, POPE, &c.

Some kind of hierarchy, both of orders and of jurisdiction, may, from the nature of the case, be looked for in every religious system that has attained any considerable degree of visibility and external organization. The ancient Jewish and Egyptian hierarchies, for example, find parallels in Parsism and Mahometanism; while in some regions Buddhism has attained a degree of complexity in its ecclesiastical government strikingly suggestive of many features of the present Roman hierarchy.

HIERAX, or **HIERACAS**, a learned ascetic who flourished about the end of the 3d century at Leontopolis in Egypt, where he lived to the age of ninety, supporting himself by calligraphy and devoting his leisure to scientific and literary pursuits, especially to the study of the Bible. He was the author of Biblical commentaries both in Greek and Coptic, and is said to have composed many hymns. He ultimately became leader of the so-called sect of the Hieracites, an ascetic society from which persons living in the married state were excluded, and of which one of the leading tenets was that only the celibate could enter the Kingdom of heaven. This doctrine was based on a somewhat too literal interpretation of the parable of the ten virgins; on other points, however, Hierax followed Origen in allegorizing Scripture; thus he thought that the narrative of the fall and the doctrine of the resurrection ought both to be taken in a spiritual sense. It is upon this apparently Manichean view of matrimony, taken along with his denial of the resurrection and of a visible paradise, and his assertion that infants, as incapable of "striving lawfully," can-

not inherit the kingdom of God, that his reputation as a heretic chiefly depends.

HIERO, the name of two rulers of Syracuse.

HIERO I., displacing his infant nephew, succeeded his famous brother Gelon as tyrant of Syracuse in 478 B.C. His rule was more tyrannical than Gelon's had been, and his jealousy of his more popular brother Polyzelus (who was at the head of the army, and had married Gelon's widow Demarete, daughter of Theron of Agrigentum) ended in an open quarrel, in which Theron sided with Polyzelus. The brothers, however, were reconciled, and Hiero married Theron's sister. From the slight information extant regarding Hiero, his influence seems to have been very great. He removed the inhabitants of Naxos and Catana to Leontini, and peopled Catana, which he renamed *Ætaa*, with Dorians. He was also an important factor in the history of Agrigentum, of Rhegium, and of Locri; and he saved the Greeks of Campania from the Etruscans, whose naval power he destroyed by his great victory at Cumæ (474 B.C.). Though despotic in his rule, he was a hearty patron of literature, and numbered among his friends such names as *Æschylus*, *Bacchylides*, *Epicharmus*, *Simonides*, and *Pindar*—the last of whom celebrated his victories in the Grecian games. He died at Catana in 467 B.C.

HIERO II., king of Syracuse, was the illegitimate son of a Syracusan noble, Hierocles, who claimed descent from Gelon (see *GELON*). His birth must have taken place before the year 306 B.C. On the departure of Pyrrhus from Sicily (in 275 or end of 276 B.C.), the Syracusan army and citizens alike marked their approval of Hiero's military and popular qualities by placing him at the head of the troops, and he materially strengthened his position by marrying the daughter of Leptines, the leading citizen. A body of Campanian mercenaries, who had been employed by King Agathocles of Syracuse, had taken the designation of Mamertines, and occupied Messana. From this stronghold they harassed the Syracusans. Hiero led his army against them, and in the engagement that ensued he abandoned to the enemy his mercenary troops, whose fickle disposition he distrusted, and retreated with the rest of his soldiers to Syracuse. There he raised a native force, with which he drove the Mamertines into the corner of the island, defeated them in a pitched battle, and was prevented from capturing Messana only by Carthaginian interference. His grateful countrymen then chose him king (270 B.C.). In 264 he again returned to the attack, and the Mamertines called in the aid of Rome. Hiero at once joined the Punic leader Hanno, who had newly landed in Sicily; but being defeated by the consul Appius Claudius, he withdrew to Syracuse. Pressed by the Roman forces, he was in 263 compelled to conclude a treaty with Rome, by which he was to rule over the south-east of Sicily and the eastern coast to Taormenium. From this time till his death in 216 he remained the fast friend of Rome, rendering frequent and valuable service during the First Punic War by supplying men, material, and provisions. Presents were sent him in acknowledgment of these good offices; but the strong desire of the Romans to occupy Sicily prevented his receiving any accession of territory at the close of the war. When the Second Punic War broke out, he was faithful as ever, joined his fleet to that of Sempronius, and offered supplies of food and clothing. At home, he was a wise and just ruler. He retained the republican senate, and governed as a constitutional monarch. Munificent in his gifts to foreigners—witness his presents to Olympia, to the Rhodians, to King Ptolemy, and above all to the Romans—and in the erection of public buildings within his own domain, he was exceedingly simple in his personal tastes; he wore a citizen's dress, and was not attended by guards. So wise were his financial arrangements that they were re-

tained by the Romans after the reduction of Sicily. He kept up a powerful fleet for defensive purposes, and employed his famous kinsman Archimedes in the construction of those engines that, at a later date, played so important a part during the siege of Syracuse by the Romans. His only son, Gelon, predeceased him, and he was succeeded by his grandson Hieronymus.

HIEROCLES, a Roman proconsul, first of Bithynia and afterwards of Alexandria, flourished during the reign of Diocletian (284–305 A.D.), and is said to have been the instigator of the fierce persecution of the Christians under Galerius Cæsar in 303. He was a man of considerable intellectual culture, and wrote a work entitled *λόγοι φιλαλήθεις πρὸς τοὺς Χριστιανοὺς* in two books, in which he endeavoured to persuade the Christians that their sacred books were full of contradictions, and that in moral influence and miraculous power Christ was inferior to Apollonius of Tyana. For our knowledge of the nature of this treatise, which has not come down to our times, we are dependent on Lactantius (*Instit. Div.*, v. 2), and still more on Eusebius, who is the author of a refutation entitled *ἀντιπύρρητικός πρὸς τὰ Ἱεροκλέους*.

HIEROCLES, a Neo-Platonic writer of the 5th century A.D., was apparently a native of Alexandria. He was born most probably about the beginning of the 5th century, studied under the celebrated Neo-Platonist Plutarch at Athens, and taught for some years in his native town. He seems to have been banished from Alexandria and to have taken up his abode in Constantinople, where he endured some persecution for his religious opinions. His death must be referred to the closing decade of the 5th century, probably about 490. The only complete work of his which has come down to us is the commentary on the great Pythagorean *Carmen Aureum*, but several other writings, specially one on Providence or Foreknowledge, are quoted or referred to by Photius and Stobæus. The commentary contains several remarkable utterances, and is written with much elegance. Philosophy is there regarded in its practical aspect, as a discipline for purifying or elevating the mind by inculcating virtue and leading to truth. The most curious doctrines contained in the work are those bearing on providence and the human soul. The activity of the Divine Being, the supreme God, although eternal and all-reaching, is viewed as extending specially or immediately only to spiritual existences, or rather to the genera of such existences. The individuals are not directly the objects of divine operation, but are left to natural chance or law. In more modern phraseology there is only, according to Hierocles, general, not particular, providence. As against divine foreknowledge, perfect freedom of individual will is maintained. All that is preordained is but the connexion between volitions and their natural consequents. As regards the human soul, the teaching of Hierocles in the main resembles Neo-Pythagoreanism. He states the doctrine of transmigration and pre-existence, holds that there is an ethereal body which is purified by trial along with the soul, and regards the world as the means by which judgment upon the past actions of the individual spirit is carried out.

The earliest edition of the commentary is the Latin translation by Aurispa in 1474; the Greek text was first given by Curterius in 1583. The fragments of the works on Providence and Fate were published in 1593 by Morellus. Later editions of all that is preserved appeared in 1654–5, 1673, and 1709. The commentary alone has been edited by Ashton (1742), by Wolf (1710), by Gaisford in his edition of Stobæus (1850), and finally by Mullach (1853). The best-book entitled *δοκτεία* (edited by Schier, 1748, and Eberhard, 1869), though frequently attributed to this author, is certainly the work of a later hand. The most complete information regarding Hierocles is to be found in Mullach's edition, and in the relative portions of his *Fragmenta Phil. Græcorum*, 1860, i. 408 sq. Cf. Zeller, *Phil. d. Griechen* (2d ed.), iii. 2, pp. 681–7.

HIEROGLYPHICS

INTRODUCTION.

THE term hieroglyphics is used, with others, by Greek and Latin writers to describe the sacred characters of the ancient Egyptian language in its classical phase. It is used by the moderns for various systems of writing in which figures of objects take the place of conventional signs. This article is limited to an account of Egyptian hieroglyphics, with some notice of the derived systems called hieratic and demotic.

It is no longer necessary in an article like the present to give a history of the interpretation of hieroglyphics and a sketch of the grammar of ancient Egyptian. What students need is a statement of the main results as to the Egyptian characters themselves and a systematic bibliography.

The written language of the ancient Egyptians remained the same from the date of the earliest monuments (Third Dynasty) until the age of the Ethiopian kings (B.C. cir. 700), when a vulgar dialect expressing the common speech is first found in written documents. Then, if not earlier, the older phase of the language became the classical Egyptian, sometimes called the sacred dialect, to distinguish it from the vulgar dialect. The classical Egyptian was used almost as late as the fall of paganism generally for all documents but legal and commercial ones, for which the vulgar dialect was used.¹

It is necessary to observe that although Egyptian is not proved to be a Semitic language, it contains in its oldest known form undoubted Semitic elements, both in structure and roots. The constant comparison with the Semitic languages which is here necessary is therefore not merely employed for the sake of the analogies that may be discovered, but on the ground of partial affinity, which, however, must not be strained.

It must also be borne in mind that the grammar of ancient Egyptian is in its infancy. We know many of its principal facts, but we do not know them accurately. For instance, we know the forms of many tenses of the verb, and can perhaps place these tenses in groups, as past, present, and future, but we cannot define the different senses of the various tenses of each group. Similarly, in Coptic we do not always know the shades of difference within a group of tenses. It may be that in Coptic these shades have disappeared through the decay of the language, but it would be rash to affirm this of the classical Egyptian. Thus this essential part of the grammar will not be understood until the verb has been thoroughly worked downwards from the oldest texts through the classical language, then through the demotic, and then the Coptic, and again in inverted order from the Coptic upwards. The same labour has to be performed for the whole grammar in each of the three phases of the language, before we can speak with any certainty of Egyptian grammar. This is said in no disparagement of the admirable work already done, but as a necessary caution to the student.

¹ As early as the time of the Empire differences of dialect due to difference of speech in Upper and Lower Egypt had crept into correspondence (Brugsch, *Gram. Hiér.*, 93). Ultimately vulgar forms and constructions are distinctly traceable in the sacred language (Id. l. c.; cf. Id., *Geogr. Inschr.*, i. 94, 95). There are also natural changes due to development or decay or both, and artificial changes due to fashion. Modifications of grammatical forms and the growth of style are instances of natural changes, and the direct borrowing of Semitic words by the scribes of the Ramessides, and what is still more remarkable, the actual Semiticization of Egyptian words, are examples of artificial changes (Maspero, *Hist.*, 337, 338).

The following sections are abridged (to p. 806, end of section on "Secret Writing"), with additions and modifications, which are noted by their being included in parentheses, from M. de Rougé's *Chrestomathie Égyptienne*, Abrégé Grammatical.

THE SYSTEMS OF WRITING.

The elements of Egyptian writing are composed of a certain number of actual objects, natural or artificial, imitated by drawing or engraving.

Egyptian writing falls into three systems—(1) hieroglyphic, (2) hieratic, (3) demotic or enchorial, the hieratic being a simplified form of hieroglyphic, and the demotic of hieratic. The complete designing of hieroglyphics required skill and time. They thus came to be reduced in writing to the simplest forms which retained the leading characteristics. These were called by Champollion linear hieroglyphics. The linear forms not lending themselves with sufficient readiness to very rapid writing, a further abbreviation was made, by which the forms became almost conventional,—the original type usually ceasing to be immediately recognizable: this cursive system Champollion called hieratic. The demotic writing is a new abbreviation of the hieratic: it gradually departs so far from the original types as to appear to consist of arbitrary signs.

Hieroglyphics are written either in horizontal lines or vertical columns, and are ordinarily read from the right. The heads of animals and the like shew from what direction to begin reading. Hieratic and demotic are written from right to left, in horizontal lines. In very early times hieratic is sometimes written in vertical columns.

(The hieroglyphic is a lapidary system, the hieratic and demotic purely systems for common writing. Consequently the hieroglyphic is the most difficult of the three to read, as the engraver or painter paid great attention to the symmetrical appearance of each group of signs, and grammatical forms were hence often omitted. In hieratic and demotic the signs follow each other without interruption of the natural order, and the grammatical forms are usually given, and even more fully.)

CHARACTERS IN RELATION TO THEIR USE IN WRITING.

Egyptian writing is composed of a mixture of signs of two distinct classes—(1) ideographic, each sign representing an idea; (2) phonetic, representing a sound, either (α) a simple articulation (alphabetic) or (β) a complete sound, *i.e.*, a complete syllable (syllabic). The two classes were combined according to fixed rules in writing words.

IDEOGRAPHIC SIGNS.

This class may be best divided into (α) representative signs and (β) symbolic (tropical).

The representative signs exactly express the idea of the object of which they present an image, as \star a star.

The symbolic (tropical) signs represent an idea by the aid of certain analogies which the mind sees between the symbol and the idea attached to it. A simple symbol presents a single object, as the sun \odot , when used in the symbolic sense "day." A symbol is complex when uniting more objects than one to convey to the mind a single idea, thus a star suspended beneath the celestial vault $\overline{\star}$ represented "night." Unde

complex signs should be placed figures of divinities in which the human form has special headdresses or insignia.

The value of ideographic signs may be discovered in various ways. The representative signs only need that the thing represented should be determined. The symbolic signs are often (rather, sometimes) explained by classical authors; they may also be explained by careful study of bilingual documents, as the Rosetta Stone (and the Decree of Canopus). The sense, and more certainly the reading, can be discovered by an exact knowledge of the words written by phonetic combined with ideographic signs, and above all by the variants allowed in writing the same word with signs of different classes.

(The result may be thus tabulated :

Ideographic Signs.		Phenetic Signs.	
Representative.	Symbolic.	Alphabetic.	Syllabic.
Dr. Brugsch in his <i>Gram. Hiér.</i> (p. 3) gives the following scheme :			
Phenetic Signs.		Ideographic Signs.	
Alphabetic.	Syllabic.	Special.	General.

Here the ideographic signs are classed, not according to their nature but according to their use, which will be later noticed. M. de Rougé's seems the more logical classification.)

PHONETIC SIGNS.

As the phonetic signs represent either (a) a simple articulation or (β) a complete sound, i.e., a complete syllable, the hieroglyphic method comprehends (a) an alphabet and (β) a syllabary.

Champollion held that the alphabet originated from giving to each object the phonetic value of the initial of its name: thus the mouth  "ro" would become "r." This probable principle cannot now be tested for a great part of the alphabet, probably in consequence of the loss of many archaic words.

The alphabet of the Greek and Roman periods presents a great number of homophones for each articulation. The more we advance towards antiquity the more the method simplifies, and the alphabet of primitive times admits but a very small number of homophones. Dr. Lepsius (*Lettre à Rosellini*) first scientifically treated this distinction.

ARTICULATIONS OF THE EGYPTIAN LANGUAGE.

The determination of the exact number of articulations which the scribes distinguished in the Egyptian language presents great difficulties. Comparison with the articulations of languages which occur in bilingual texts cannot give sufficiently precise results, for the shades of sound are far from being the same in the languages thus placed in juxtaposition. The Romans and Greeks had many letters which, though quite distinct in their languages, the Egyptians confounded in their transcriptions. On the other hand, there were some Egyptian articulations preserved in the Coptic language which had no special representative in Greek or Latin; hence certain letters derived from the demotic were added to the Greek alphabet on its adoption by the Copts. (It must also be remarked that the Greek and Roman rule was an age of literary decay and ruin for classical Egyptian, in the depression of which little effort seems to have been made to represent accurately foreign sounds. The student must not be misled by the greater accuracy at this time in rendering the vowels, which was merely due to the decay of the system of

writing, by which the Egyptian vowels usually following certain consonant signs came to be disregarded.) Happily those Egyptian articulations which were unknown to the Greeks and Romans have at least analogues in the Semitic languages. Moreover, the many transcriptions of Semitic words (made while the Egyptian was in full vigour), joined to the traditions of the Coptic language (which has ceased for a hundred years to be a living speech), enable us to appreciate sufficiently those articulations unknown to the Greeks and Romans (and this indication may be followed in the cases of the rest of the letters).

The words common to Egyptian and Semitic in the earliest known condition of the Egyptian language must be omitted from comparison; the more exact transcriptions of the scribes of the Ramessides (Dynasties XIX., XX.) must take precedence of the looser ones of the earlier period of the Empire (Dynasty XVIII.). Coptic, having long existed in a languishing state and under the influence of Arabic, whence the colouring of the latest dialect, the Bashmuric (Revilleut ap. Rossi, *Gram. Copto-Ger.*, 30, n. 1), and certain peculiarities of the present pronunciation, is not an absolutely safe guide.

It might be thought that the study of the various modes in which words are written would furnish an exact table of homophones, and give us at once the list of distinct articulations; thus we might suppose that variants shewing two characters might enable us to assume their identity, as when in reading Greek we assume that θ is the same as ϑ. But in Egyptian, as in other written languages, there are certain licensed irregularities of orthography, and also oscillations between the different shades of sound in the same class of letters when used for the same word: a small number of variants between two letters therefore does not prove their perfect homophony. Hence certain differences of opinion among Egyptologists, according to the weight, greater or less, which they give to this or that series of variants. Thus the number of letters under the "t" group differs with different scholars.

Without denying that there may have been some shades of sound in the different signs here called homophones, as in the sounds represented by the English "th," the chief guide should be the estimate the Copts made of the elements of their language, when they adopted the Greek alphabet, completing it for their purpose by adding six special letters taken from demotic writing.

The Egyptian Christians in adopting the Greek alphabet, which had vowels with fixed sounds, made their writing undergo a radical change: up to that time they had only vague vowels which were, as in the Semitic alphabets, simple aspirations, susceptible of being coloured by the sounds of different vowels (but this vague character must be limited by the vowels falling, as in Semitic, into three groups of sounds; the vagueness was therefore not unlimited. This characteristic of the old Egyptian influenced the Coptic, which presents in the vowels varieties of orthography of the same word, these varieties, however, usually falling within the three ancient groups. It is only in the Coptic helping vowel that absolute vagueness is found, like that of the primitive "shēva" of Hebrew.)

Following these indications we find 15 leading articulations in Egyptian: the shades of sound which may be most certainly distinguished would indicate an alphabet of 21 divisions. They are transcribed by letters taken, one, x, not to be confused with the Coptic x, excepted, from the Latin alphabet, according to the principles of the Standard Alphabet. Cf. Lepsius. *Standard Alphabet.*

Semitic transcriptions have a much wider range, which comprehends nearly all the vowel sounds.

(The unwritten aspirate or short vowel is not noticed in this place by M. de Rougé. It will be seen, under the Section on "the Transcription of Vowels Omitted," that he does not admit the transcription of an unwritten vowel except as a makeshift, or in other words, that he does not allow the Egyptians to have had a vowel sound never written. The existence of the supposed vowel seems, however, certain on these grounds. Some syllabics never take a vowel except for an unusual form,—the root and the ordinary derivatives never being vowelled, and a vowel only appearing in what is obviously a derivative formed by lengthening the vowel. Further, the Coptic has such a vowel marked by peculiar forms \curvearrowright or \curvearrowleft above a letter, or in the latter case above a letter or syllable, indicating that the sound, here generally ϵ , was omitted in writing by the ancient Egyptians; and still more remarkably the Coptic use is sometimes found where the older writing would lead us to expect it. In ancient Egyptian the use of this helping vowel is implied, as an aspirate in a syllable written with a consonant alone, as mm n , m , r ; in Coptic st , et , p , and as a medial vowel in a syllable of two consonants, as tm , "not," in Coptic $\text{T}\epsilon\text{L}$. In Coptic, as already mentioned, it is generally read ϵ , ξ , but had this been its constant sound it would have been represented by ϵ , and would of course have been needless. It is safest to read the old Egyptian helping vowel ξ . It resembles the Hebrew Shéva, as including its variants Hateph-Pathah, Hateph-Segol, and Hateph-Kames.

M. de Rougé's section on this subject seems wanting in his usual clearness. This is, however, due to the inherent difficulty of the subject. The Egyptian vowels, except when used as semi-vowels, are undoubtedly vague. Thus, in the writing of Semitic words under the Ramessides, while the consonants are most carefully represented, the vowels affected by those consonants are frequently used, and the apparent pronunciation is distorted. Consequently, though we have no difficulty in separating the vowels into the a , i , and u group, adding the helping vowel, or short ξ , because the use of the i and u vowels as semi-vowels gives them and the third vowel (a) thus limited a certain definite character, yet, when we have to treat of vowels pure and simple, the distinction of these classes vanishes. Thus the idea of fixed vowels, with however wide legitimate extension, is constantly rising in the enquiry to be as constantly suppressed by the vagueness of their use. It must, therefore, be held that the transcriptions we adopt do not give the accurate pronunciation, inasmuch as the vowel constantly, but not always, depended upon the consonant preceding, and vowel complements are even added where they were not pronounced. This is proved by Greek transcriptions, as will be seen later. On the other hand, the voweling of Greek and Latin proper names shows that the vagueness of the vowels was not absolute, for the Egyptian scribes in the decay of the old style, no longer bound by the ancient usage of complements, employed the vowels with such accuracy as their limitation in sounds permitted, subject to the carelessness of the age. Of course these vowels could not accurately represent the Latin five or the Greek seven. Perhaps it may be suggested, in conclusion, that some idea of the Egyptian vowel system may be formed by a comparison with unpointed Hebrew.)

LABIALS.

While approaching ph or f , \curvearrowright is distinct, for the Copts who adopted Ψ as necessary for the aspirated p of the Memphitic dialect, also considered the \curvearrowright needful, of which their Cf is the demotic sign in a modified form. In some words \curvearrowright is employed as a variant of u . On account of this function it has been transcribed by v instead of f . In consequence of this use it was sometimes omitted:

thus mm ni , for mm nef , "blood,"

Coptic $\text{C}\epsilon\text{C}\text{O}\text{C}$. (M. de Rougé calls this letter, so used, a vowel or variant of u , and in the example just cited characterizes it as a short vowel, but it seems more analogous to v after a vowel, when not quiescent, in the present or ordinary Hebrew pronunciation.) In Greek words \curvearrowright does not render ϕ ; the Egyptians used either O , p , or the combination OP , ph . But in the transcription of Semitic words we sometimes find \curvearrowright for D . In Coptic, besides Cf , this letter sometimes becomes Ψ and R .

Like the Hebrew D the Egyptian b comprised the two shades of sound D b and D (bh or v), at least in the less ancient periods. The Copts seem also to have known the two sounds, though their one R has been generally transcribed by v . The transcriptions of the Greeks do not aid us, for their β was probably sounded v . The evidence of the Semitic words is perhaps more precise in the system of transcription

of the (hieratic) papyri of the Nineteenth Dynasty. D , b , is rendered either by p or by the group X , bp ; D (bh) by J alone: the ordinary sound of b should therefore approach v . In the hieroglyphics they were often content with R , b , homophone of J , for D . (The weight of this reasoning partly depends upon the antiquity of the Masoretic punctuation, which is, however, supported by the double rendering of the Egyptians.)

The compound bp , introduced for Semitic words, is found later employed in hieratic for Egyptian words, no doubt to characterize the pronunciation b , D ; better than by R alone, or the group

JR , which serves as its variant in these same words. The signs J and R sometimes interchange; oftener JR replaces R alone; they also exchange, but rarely, with p and f . The ancient b produced regularly the Coptic R , and by affinity OY , N , Φ , Cf , and L .

The two signs of p , O and X , are complete homophones. The Memphitic dialect aspirated p , and used Ψ in many words where the Sahidic used N . Here the Sahidic has been more faithful to the ancient pronunciation: in fact ϕ Greek was sometimes rendered by the group OO , ph , and the Hebrew D by \curvearrowright , f . This ancient Egyptian letter was then p ; it also corresponds exactly to D . It was further used to transcribe approximately D , as already remarked.

It produced regularly in Coptic the Sahidic N and the Memphitic Φ . Affinities occasionally introduced Cf or R . The ancient p also presents some instances of varying with b .

PALATALS.

This class of letters lends itself to great varieties of pronunciation which render them difficult to understand; it is in their nature to modify themselves considerably by the simple change of the vowel which follows them. The Greek and Roman transcriptions would lead us to consider the four signs L , U , J , and D as perfect homophones. But we are led to another opinion, if we consider the transcriptions of Semitic words, and the Coptic derived words.

The Semitic transcriptions afford the following results: 1, J and (Y answering to) ξ (gh) are almost always rendered by D ; 2, D corresponds to U , and p to L ; but this second rule is not so faithfully observed as the first.

In the Coptic language there are here two distinct types: 1, K Sahidic, aspirated as X in the Memphitic; 2, G Sahidic corresponding to X Memphitic, but sometimes identical.

Taking the Copts as guides we distinguish two palatals, which we mark as k and ξ . F did not exist in their writing, but in some rare cases which do not correspond to a special ancient letter in a small number of words where it is derived from U , k , it is produced by the presence of the nasal which precedes; thus ANF , I , from QO .

In studying more closely the three signs L , U , J , we are easily convinced of the perfect homophony of J with U . The equality of L and J may seem more doubtful; variants exist, but they are not frequent. However, we find the group LJ , where the first letter only doubles the second, as we have seen in the group JR , and we are thus authorized to connect intimately L , J , and U , and transcribe them by k .

To this articulation correspond regularly, in Coptic, K Sahidic and X Memphitic, G and X less frequently, S and Z as rare exceptions.

The rule of derivation is different in what concerns D , and it is there above all that we recognize the distinct type preserved in the Coptic G . The sign D , which we transcribe k , shows some ancient cases of variants with the preceding signs, and the Greek transcriptions do not give us sufficient reasons for making a distinction. The Semitic transcriptions are more decisive; the D , as already noticed, is quite specially set apart to render J , and Y answering to ξ . The Coptic derived forms strengthen this first result; they quite regularly class themselves under the Sahidic G , answering to the Memphitic

Ⲭ, or under the Ⲅ in both dialects. The exceptions are as follows, in order of frequency:—1, Ⲅ Sahidic, Ⲭ Memphitic; 2, Ⲭ Sahidic, Ⲭ Memphitic; 3, Ⲭ in both dialects; 4, Ⲭ Sahidic, Ⲅ Memphitic.

The graphic origin of the Coptic Ⲅ is doubtful. It is incorrect in our judgment to derive it, as hitherto, from the demotic Ⲅ, coming from Ⲅ, hieratic of Ⲅ: the suffix of the second person Ⲭ has been rendered as far as the latest periods, almost contemporary with the Coptic, by this demotic sign; consequently we ought to find it in Coptic under the form Ⲅ if this letter came from that sign; on the contrary, Ⲭ is used for this pronoun. Ⲅ may have come from the demotic form of Ⲅ, through the hieratic.

DENTALS.

The exact appreciation of the Egyptian dentals is hard. It seems certain that the three homophones Ⲅ, Ⲅ, Ⲅ, answer to a *t*, and that Ⲅ, Ⲅ, are represented in Coptic by the special articulation Ⲭ. The sign Ⲅ seems to have the character of an intermediate shade of sound. In the Greek and Roman names, *τ*, *θ*, and *δ* are transcribed by all the signs without distinction (the Roman being transcribed through Greek forms). In the Semitic transcriptions Ⲉ and ⲩ are rendered by Ⲅ, Ⲅ, Ⲅ, and more rarely Ⲅ; Ⲉ is transcribed by Ⲅ with a marked preference; Ⲉ and ⲩ answer exclusively to Ⲅ and its homophones (including a later sign).

The Coptic offers two certain types, Ⲉ, becoming Ⲙ Memphitic, and Ⲭ; the trace of a third variety seems also preserved in the syllabic Ⲉ. We are thus led to distinguish three consonants *t*, *θ*, and *t'*.

The three signs Ⲅ, Ⲅ, Ⲅ, *t*, conduct themselves as perfect homophones. The Greek and Roman names shew them to be used for *τ*, *θ*, *δ*; but the hieroglyphs when they sought a more scrupulous transcription of *θ* used the group Ⲅ, *th* (cf. Ⲅ, *ph*), which shews that originally the Egyptian *t* did not lend itself to the aspirated sound. The Leyden MS. with Greek transcriptions thus places *θav* in correspondence to an Egyptian word, written Ⲅ Ⲅ Ⲅ *Tuhan*, in which the first *a* is a "mater lectionis," of no value in pronunciation. In Semitic words Ⲅ, Ⲅ, Ⲅ, served to transcribe regularly Ⲉ and ⲩ, sometimes also Ⲉ, but more rarely.

We observe no preference for transcriptions of ⲩ; this letter, which is not frequently found, corresponds even to Ⲅ, *t*, in the name of Potiphar. We may conclude that the special sound of the ⲩ had no existence in old Egyptian. The Coptic derived forms have but one type Ⲉ for Ⲅ and its homophones; the Memphitic aspiration changes it to Ⲙ; following the rules of affinity we find some cases of derivation with Ⲭ.

We pass at once to the third dental, *t'*, of which the differential characteristics are more marked; perhaps the intermediate consonant may be more easily defined afterwards. The two signs, Ⲅ, Ⲅ, which we transcribe *t'*, interchange in many Egyptian words; they are both varied with the very common syllabic Ⲅ, *t'a* (which became an alphabetic sign though retaining its vowel, like our *g*); they act in exactly the same manner in the transcriptions and in the Coptic derived words. The hieroglyphs employed them, but very rarely, to transcribe the Greek *τ* and *δ*, and the Greeks felt some difficulty in transcribing this articulation; thus we find *t* rendered by *τ* and *δ*, or by *α*; thus *Sa-n-t'aho* is rendered by *Sensaes*, and *Har-ant-atef* by *Arontotes* and *Arendotes*.

In the cartouche of Cambyses the Persian articulation *z*, *j* of Rawlinson, Ⲅ, is found; it is transcribed by Ⲅ, *t'*, but not constantly; variants shew a simple *t*, Ⲅ. Therefore there was not a perfect identity between the Egyptian *t'* and the Persian *z*. The Hebrews had two sibilants more or less shading off into cerebrals, *z* and *y*; they are constantly transcribed by Ⲅ, *t'*, and its homophones, and not by *t*; but we do not remark a preference in favour of this or that sign for either of the two Semitic letters, and this confusion shews that there was an approximate correspondence.

The Coptic derived forms from the ancient *t'* are classed according to two rules:—they are written either (1) with Ⲭ in the two dialects, or (2) with Ⲭ Sahidic, corresponding to Ⲅ Memphitic,—the dialect of Upper Egypt shewing a higher exactness. The exceptions shew us—1, Ⲉ Sahidic, Ⲙ Memphitic; 2, Ⲅ Sahidic, Ⲭ Memphitic; 3, Ⲅ; 4, the palatals; *i.e.*, all the letters which shew a kind of affinity with this dental, of which we cannot now fix the pronunciation beyond saying that it approached the sibilants and the cerebrals. The Copts preserved it in Ⲭ, which comes from the hieroglyphic Ⲅ, through the hieratic Ⲅ, Ⲅ, becoming in demotic Ⲅ: this was developed and made regular by the Copts. The Copts cannot now give precise information as to the pronunciation of Ⲭ; in the last century, an attempt was made to indicate it by *sj*. Dr. Brugsch proposes for the ancient letter *z*, and Dr. Birch *j*; it seems to us that the conventional *t'* is more suitable to the Egyptian variants of the articulation, which constantly make it approach Ⲅ, *t*.

In the eyes of the ancient Egyptians the letter Ⲅ, *t*, was a near neighbour of Ⲅ, *t'*; it could even be considered as a homophone if we had only the evidence of the variants; for variants between Ⲅ and Ⲅ are numerous, and found in the earliest texts. The variants between Ⲅ and Ⲅ, Ⲅ, Ⲅ, are rare enough, and belong above all to the late periods. But the Semitic transcriptions indicate the principle of a distinction. Far from using it to render *z* and *y*, Ⲅ is connected with Ⲉ with a very marked preference. From the Nineteenth Dynasty, when the system of these transcriptions appears to have been made regular, on account of the many relations established with the neighbouring nations by conquests and emigrations (into Egypt), this preference became so constant that it led Dr. Brugsch to transcribe Ⲅ by a *d*.

The exceptions to this rule place the Ⲅ beside ⲩ and Ⲉ, rather than the cerebrals.

In Coptic the derivatives of Ⲅ, *t*, do not act like those of ancient words usually written with *t'*. We find the derivatives of Ⲅ regularly under the dentals Ⲉ, Ⲙ, Ⲉ, sometimes also under Ⲭ, but in very small number. The verb *tu*, "to give," ordinarily written Ⲅ, becomes in Coptic Ⲉ. This sign, which the earlier Copts pronounced *di*, was considered a simple ligature for Ⲉ and Ⲉ. But

Dr. Brugsch has remarked that Ⲉ resembles the demotic Ⲉ, corresponding to Ⲅ, "to give," too much for the likeness to be due to chance; there was here a recollection of the softened sound peculiar to Ⲅ, and the Copts took the Ⲉ from demotic with their other special letters.

Evidently these two groups of documents may induce us to mark the Ⲅ as a special letter, but this letter could not be a *d*. In fact, the Copts excluded Ⲅ from their native words, and the hieroglyphs indicated that the Ⲅ was not a true *d*: when they would transcribe more exactly the Latin *d*, which they found in foreign names, they employed a double letter, *nd*. We notice this in variants of the cartouche of Darius for the Persian *d*, and for the Latin *d* in the surname Ⲅ Ⲅ Ⲅ Ⲅ, *nt(a)kik(u)s*, for *Dacicus*, inserted in the cartouche of Trajan. This wholly artificial orthography aids us to appreciate a peculiarity of the Egyptian dentals, that after the nasal the pronunciation softened in the direction of *d*. This explains many Greek transcriptions which shew the *δ*, as *Zpēdērys*, which represents *Nes-bi-n-tet*.¹ The *d* being out of the question we select *t* as near the point of view of the Egyptian variants where Ⲅ replaces Ⲅ.

LIQUIDS.

The three signs Ⲅ, Ⲅ, and Ⲅ exactly answer to *m*; the transcriptions are uniform, always *μ* Greek and ⲩ Semitic.

The Coptic derived forms are almost always Ⲅ, some rare exceptions presenting Ⲉ, Ⲙ, Ⲉ. One must be very careful in Coptic not to confound a radical Ⲅ with that which comes from Ⲉ by assimilation before a labial, as in the Sahidic particle ⲄⲄ, coming from ⲄⲈ, "in," before the article Ⲉ. It is also to be remarked

¹ Cf. the Gnostic word *Sabat*, which does not differ from the other but by the absence of the flexion *n*, and retains the *t*.

minativ of sound from the ordinary use as determinative of sense.)

Syllabics are divided into two classes—1, an articulation and one or more vowels; 2, two articulations (usually with a medial helping-vowel unexpressed. All are, no doubt, monosyllables, although a syllabic like *aaa* has the appearance of a dissyllable; here, either the first *a* has no force, or the two indicate a long vowel.)

The first class of syllabics, an articulation and a vague vowel, is scarcely distinguishable from the letters of the alphabet. The distinction is thus determined: 1, the simple letters were used as phonetic complements; 2, the syllabics do not seem to have been used quite indifferently for all kinds of words. We frequently find allusions, relations direct or remote, which have originally induced their choice for the purpose of writing this or that radical. (This is strictly analogous to the principle of the syllabary of Assyro-Babylonian in its Akkadian and Semitic developments, though in its application that principle led to wide polyphony, in consequence of an ideograph taking different sounds according to the cognate senses in which it was used.)

It is also possible that the syllabics were sometimes employed to give an idea of the sound of the vowels. But if they had this use primitively, they did not retain it, for we cannot establish this property in a constant manner in the hieroglyphic transcriptions of Greek or Semitic words. (It is indeed the converse use of the vowel most affected by a consonant or of the syllabic with its vowel which is our chief embarrassment in the reading of Semitic transcriptions.)

There were also some signs corresponding to three articulations which could be used as syllabics. Here the cases of homophony are much more rare; we have to do with different acceptations rather than different radicals, but the ideal bond between these different acceptations may escape us now. (These are still monosyllables.)

POLYPHONY.

There are characters which had various pronunciations. There are three kinds of polyphones:—

1. A sign can answer to various words which belong to the same class of ideas; thus, the calf's ear, , answers to the words , *mest'er*, , *ānhh*, and , *at*, which seem to have all signified the ear or some special part of this organ. The words , *scm*, and , *setem*, "to hear," are two new values, on the same principle. One might add to this first class the very near values produced by variants of pronunciation or writing for the same word, such as *ta*, *taq*, *ta*, *at*, *aat*, *aat*, *uatu* for , and the forms more or less developed of a single root, but these are rather extensions of a word than true instances of polyphony.

2. The same sign might have been chosen as symbol of a certain number of ideas without any true bond between them, at least to our view: thus , answers to the phonetic , *usech*, "largeness," to , *āb*, "offering," and , *hent*, "regent" (fem.)

3. A sign may have become syllabic and be used for several purely phonetic values taken from the words in which it figures, on the two principles explained. Thus in the syllabary, the sign , which symbolizes the idea "gift," answers to two roots, *tu* and *mā*; these give in their turn to , the values , *tu*, and , *mā*, even in words where the idea of gift no longer exists.

Such is the series of facts which has produced Egyptian polyphony. The number of figures suitable to design and with which one could reasonably charge the memory being limited, we should expect to find polyphony more or less developed in every system of writing originally ideographic. The syllabic polyphony of Assyrian seems to have been produced by wholly analogous circumstances, though the change from the original language habitually veils the connection of values.

Polyphony is a source of great difficulty, and science has still much to do to fix the different phonetic values of the polyphones. Often our decision is made on the evidence of phonetic complements, and in hieratic it is seldom that this aid is wholly omitted.

Thus  is easily recognized as *mā*.  But our ignorance is not always thus aided, and the choice of the suitable word sometimes can only be indicated by a profound study of analogous texts.

The following list gives an abridgment of Do Rongé's lists of syllabics, and contains the most common signs, the important polyphones being indicated by asterisks, and their principal varieties of sound being given in the fourth column. The method is varied from that of the *Chrestomathie*.

DETERMINATIVES.

Champollion described as determinatives certain ideographic signs which were placed after words phonetically expressed. The use of each of these signs is more or less extended. The greater part are used for one radical, or at least for one and the same idea. For such determinatives the proper place is the dictionary. But there is a class of determinatives placed after different words, often many in number, and therefore called generic determinatives. The determinative is attached to the radical, and has nothing to do with the grammatical use of a word as noun or verb. (M. de Rougé gives a list of above a hundred as necessary for the student of Egyptian grammar, leaving out those of more restricted use.) Science has not yet wholly accomplished its task in this section. (Necessarily the exact definition of the range of a determinative requires a careful induction from its use.)

(The table which follows is but slightly abridged from M. de Rougé's, after comparison with Dr. Brugsch's in his *Grammaire Hiéroglyphique*, where a somewhat fuller but less logical list is given, apparently founded on that of the French savant. The reason for here giving a larger proportion of determinative than of syllabic signs is that the sense of the determinatives when logically arranged, as by M. de Rougé, present a key to the whole construction of the Egyptian system of ideographic signs, and afford us a remarkable insight into the genius of the language.)

TABLE OF GENERIC DETERMINATIVE SIGNS.

SIGN.	VARIANTS	REPRESENTING	DETERMINING IDEAS.
1		ceiling	sky, ceiling; to raise, superiority
2		ceiling with star	night, obscurity
3		sun	sun, light; divisions of time
4		star	star, constellations; gods; divisions of time
5		hilly country	country, mountains; nations
6		oval	islands, oases maritime countries
7		?	cities, villages
8		country divided	nomes, districts, fields
8a		same?	territories and their portions, dikes; mud
9		waves	water, liquid, sea, rivers; to wash; freshness; level
10		flaming censer	fire, heat; zeal
11		man (squatting)	proper names; pronouns and participles
12		man acting	more general, often used in Saitic period for the more special determinatives following the next
13		man and woman	human race, its divisions, classes; participles pl.
14		man with long beard	gods, august persons, kings
15		personage enthroned holding whip	ancestors, princes, kings
16		similar, kneeling	similar; defunct persons, manes
17		man squatting, his hand to his mouth	actions of the mouth, eating, speech; thought
18		man raising hands	adoration, invocation, prayer
19		man bound	enemies, prisoners; perverse
20		man stamping and striking himself	impiety, perversity; enemies
21		man, slain	enemies; to strike; death; massacre
22		man, his right hand raised	exclamation, invocation
23		(seated) man, arms raised	height; grandeur; joy
24		man, with staff	chief, great, distinguished

TABLE OF GENERIC DETERMINATIVE SIGNS—continued.

SIGN.	VARIANTS.	REPRESENTING	DETERMINING IDEAS.
25		same, leaning on staff	old age; to end
26	(seated, holding oar)	man, holding club (or oar)	force in general, violence
27		child, hand to mouth	infancy, youth; to suckle, education; rearing
28	(the same, horizontal)	mummy	embalming; manes; rites; images, types, forms
29		funeral conch, without or with mummy	mummies; death, disease; embalming; to lie down, rest
40	varied by many attributes	woman squatting	woman, goddess; fem. pronouns and particles
31		head of man in profile	head; superiority
32		curl	hair; black, colours in general; grief; turns
33		human eye, iris, pupil	to see, to awake, to know; enemy
34		eye weeping	tears, grief
35		nose, calf's head	to breathe, smell; joy, pleasure
36		tooth	eating; speech; hard objects, stones, &c.; regions, directions; everything relating to the earth and fields
37		hand holding small club	all actions implying the use of any force
38		hand, the palm below; foot of bird lying down	arms, shoulders, sides; directions; gentle actions, rest, gentleness, accord, songs
39		a breast and two arms, arms and vase, arms	to embrace, unite; to squeeze, enclose; event, fortune
40		extended arms	negation, prohibition; adytum
41		phallus	male, generation; pollution; to pour out; parts of generation, in front; veins
42		bent leg	leg, foot, knee, &c.; walk; diminution and enlargement; measures of length
43		same and knife	to carry off, leap over, surpass, diminish, annihilate, violate
44		legs walking	locomotion
45		the same reversed	return, send back, repel
46		lion's hind part	behind, to follow; to revolt, refuse; force, violence
47		Typhenian animal	revolt, violence, disorder; tempests, storms

SIGN.	VARIANTS.	REPRESENTING	DETERMINING IDEAS.
48		calf's face, head	nose, nostrils; lungs; to smell, breathe, sleep; pleasure; to separate, shut up, revolt
49		head of ox on support (?)	throat, gullet, lungs, &c.; to eat; breathe
50		piece of skin	quadrupeds; objects in leather
51		bone with flesh?	members in general
52		Nile-duck	birds; flying insects
53		wagtail	smallness; vile, wicked
54	(varied)	wing	wings, feathers; to fly, rise
55		egg	egg; oviparous animals; race, descent; feminine
56		crocodile	crocodiles of different kinds, divinites connected therewith; to conceal oneself, to spy; destruction
57		kind of fish	fishes, fishing; impurity, prohibition
58		serpent	reptiles, worms; sacred serpents; names of certain genii
59		kind of tree	trees, of all kinds
60		dry branch?	different kinds of wood; objects made of wood
61		palm-shoot?	season, year, time; youth; to renew
62		bunch of flowers	plants, flowers; objects composed of plants
63	(varied according to kind of grain)	grains	cereals of different kinds; to labour, to harvest; measures
64	(varied)	bushel pouring out grain, vase full of grain	cereals of different kinds; harvest; tribute; to measure, bushel
65		ground-plan of room	abodes; places in general
66		rampart	walls, fortifications, enclosure
67		the same, falling	to stagger, crumble, destroy
68		steps	stair, to mount; to approach; foot of a monument
69		fortified enclosure	names of fortified cities (written within the determinative)
70		basin	waters, rivers, seas, canals, basins; to irrigate, cultivate

TABLE OF GENERIC DETERMINATIVE SIGNS—continued.

SIGN.	VARIANTS.	REPRESENTING	DETERMINING IDEAS.
71		canal, or road	ways, journeys; separation, to chase; times, periods
72		block of stone	stones, bricks, different kinds of rocks; objects in stone; mineral substances
73		boat	ships, boats; navigation; voyages, journeys
74		sail	sails; air; to breathe; freshness, pleasure; winds and their geographical directions
75		roll of papyrus	writings, books; designs, paintings; calculations, quantities; to know, thought, &c.
76		tie of a roll	to write, books; knowledge; to tie, close, finish
77	(varied)	cover of mummy-case; different forms of case	mummy-case, embalming; abode, divers places
78		post	to wander, journey, land; foreign peoples and names; impiety, &c.
79		graver, or plane?	to lessen, polish; ivory, bone; to clean, embalm, &c.
80		knife, or sword	to cut, prick, &c.; kill, beat; separate; whet
81		loaf	bread; victuals; provisions of all kinds; riches
82		basket with diamond-shaped object	festivals; joy, pleasure
83		basket	largeness; victuals and offerings carried in basket
84		vase with cover	oil; wax; perfumes; salt provisions
85	(especially for wine)	vase, or double vase	perfumes, fats, ointments; wine; liquids in general
86		vase	midst; repose; heart; feelings
87		saltier	crossing; mixture; multiplication; flexion, reflexion; transitive verbs
88		knot or packet	stuffs, dresses; bands, &c.
89		oval band (or seal?)	oval, orbit; name (names of royal personages written within determinative)
90		ring or circle	renewal; a time; totality; circle

SIGN.	VARIANTS.	REPRESENTING	DETERMINING IDEAS.
91	(often confused with 92)	rings	metals; precious solids; resins, &c.
92		round grains	sand; powder; flour
93		packet	to envelop, embalm; envelop, count
94		same, with jet of liquid	smells (good and bad) and odiferous objects; filth, corruption

THE READING OF IDEOGRAPHIC SIGNS.

The Egyptians used not only simple letters and syllabic signs, but also ideographs, to write words. The reading of these ideographs is obtained in divers ways. It is often furnished by the analysis of proper names of which there are transcriptions, though the result is sometimes approximative. Another method is the study of variants, when a phonetic form of a word replaces the ideographic sign, in the same text. Often also the ideograph is written as a determinative after the phonetic equivalent. (Hence the great importance of publishing collations of known texts, a work to be recommended to new students.)

When a word is written by a single ideograph, and above all when it is a substantive, it is most commonly distinguished by the marks Δ , \ominus , or their combinations $\Delta \ominus$, $\ominus \Delta$. Thus is the letter ξ , $\xi \Delta$, $\Delta \xi$, the basin.

THE COMBINATION OF SIGNS OF DIFFERENT KINDS IN WRITING WORDS.

In texts which shew a certain development, and above all in hieratic manuscripts, where the signs are always more abundant, many words are written phonetically and followed by one or more determinatives. In such a case, the determinative which is most general is written last: thus $\text{man} \text{bird} \text{woman}$, *kanchen*, "to become weak, feebleness"—Copt. Gron , soft,—where the phonetic letters are followed by the determinatives for (1) repose, feebleness, (2) crossing, bending, (3) evil, unfortunate. A word expressed by an ideograph may be followed by a generic determinative. (The same is the case when a word is written phonetically with its ideograph as a first determinative, of course special.)

EXPLETIVE SIGNS.

There are a few expletives which were not pronounced, and had a purely graphic use. The most important is the roll , the determinative of writing, knowledge, &c. It is sometimes used as a sign of separation or as disjunctive. The signs Δ , \ominus , $\Delta \ominus$, $\ominus \Delta$, are often used as pure expletives, adding nothing to the idea or the sound. Δ or \ominus is frequently added to a determinative; it is almost the rule, when the space needs it: as $\text{man} \text{bird} \text{woman} \text{roll}$ *mennefer*, Memphis. In such cases the expletive ordinarily follows the gender of the substantive, Δ for masc., \ominus for fem. The phonetic value of Δ , \ominus , as feminine final, sometimes causes perplexity, but its expletive character is clear in other cases. The sign Δ , which (like \ominus) is not always expletive, has similar uses. It is written after , thus , even for final *r*. With

it forms the group  1, not only for the substantive *har*, *hā*, "face," but also for the particle *her*, "upon," &c. In hieratic, *l* is attached to many characters, probably to distinguish them from very similar ones; thus  for  is clearly distinguished from  for *o*. It is thus used as a diacritical sign, though very variably. At the end of words we find, above all in late times, the expletive .

EXPLETIVE VOWELS AND COMPLEMENTS OF SIMPLE LETTERS.

Although the vowels were often omitted, sometimes they are added in a wholly expletive manner, which their vagueness can only aid us to understand. This is easily proved from certain words transcribed, such as *θav*, the Egyptian       *tahān*. In any other system the first *a* would produce a separation of syllable between *t* and *h*, transcribed here by *θ*. (It should be remembered, however, that the Greek could not represent a sound like *t*'han otherwise than by *θ*. The Egyptian vowel may here represent a disjunctive.) The same remark applies in the consideration of the Egyptian transcriptions of divers foreign words, of which the grammatical form is well known. Thus the Hebrew *מַרְבֻּטָּה* is written        *mār-habuta*, and the name of the Hebrew harp *קַנְיָה* is written       *kanaaur*. It has been remarked that each consonant had a kind of favourite complement, and that this complementary sign should often be treated as an expletive in reading. It has been proposed to admit for these letters inherent vowels, but this idea seems exaggerated: the alphabet is not a syllabary, for most of the letters unite with the different vowels. The knowledge of the ordinary complements of each letter is useful, especially in reference to transcriptions.

 *f*, seems to take  *fa*;  *fā*;  *fu*, are common.  has as favourite final *u*,  or  indifferently: we also find  *ba*;  *bā*;  *bi*; but  *ba*, is rare: *ba* is expressed ordinarily by ; we find            

the harder as *pirate*, *h*,  was rarely added except with the introduction of , as  , or  , *ha*.  alone united with ; its ordinary expletive is  ; for *h* is rare:

we have only found it followed by consonants or the vowel *u*. The syllabic , *hu*, much used for *h*, has for expletive .

These remarks are of much use when one desires to fill up lacunae of small extent in Egyptian texts. They explain usages, on which one general remark may be added, that the vowel , *q*, did not

unite itself readily to a certain number of letters; hence the introduction of an intermediate letter and the pleonastic forms

 , &c., for *pa*, *χp*, &c. (It must also be re-

membered that, on the one hand, the expletive vowel cannot in all cases have full weight in roots which are always monosyllabic, on the other, that we can scarcely deny it some force. Was it used to modify the consonant as when a local pronunciation of *g* in English is written by grammarians *gv* as *gvarden*? In transcriptions the expletive vowel appears, but for philological purposes must be disregarded, and the same is sometimes true of the complementary vowel. In English *g*, our only syllabic, always requires *u* as its complementary vowel: consequently when it is used for its ancestor the Semitic *koph*, as in *qoran*, an uneducated person would read and even write *qoran*.

On applying these observations to the orthography of *mārkabuta* for מַרְכָּבָּתָא and *kenānaur* for כְּנָנוּר, it is immediately evident that the deviations from the Semitic are due to the Egyptian vowel-system. In the word *mārkabuta*, the *u* is the favourite complement of the *b*, and the final *t* requires a vowel. In *kenānaur* the doubled *n* is resolved into two syllables: it could have been written with the disjunctive sign between the two "n"s and a final vowel.

It has been shown that the transcriptions of the scribes of the Ramessides from Semitic into Egyptian were very accurate so far as the consonants were concerned. It is equally evident that this was scarcely possible and practically was not the case with the Semitic vowel sounds. This remark should be borne in mind in all comparisons of Hebrew and Semitic.)

THE TRANSCRIPTION OF VOWELS OMITTED.

The vowels, particularly the complementary ones noticed above, were omitted at will in writing, and must often be added in transcription. This is easy when a definite fuller form of a word is known. But there are many words for which the variants give different vowels, and many others for which a vowelised variant has not yet been found. Most Egyptologists here use *e* for the absent vowel, which must only be regarded as a conventional sign for a gap to be filled. (There are, however, cases in which a very common word is never vowelised: here we may safely assume a very short vowel best represented by *ē*, as already noticed.)

ABBREVIATIONS AND EXCEPTIONS.

Abbreviations were rare; ideographs and syllabics rendered them needless. But there are cases in usual formulæ; as  , *nuter a*, for   , *nuter atef*, "divine father," the title of an order of priests. In the formula   , *ānχ ut'a senb*, "life, balance, health," a kind of good wish added to king's names and rendered in the Rosetta Stone *ιγίεια*,  is *ānχ*,  *ut'a* is an abbreviation, for we find the complete word , *ut'a*, in the same formula; but the  for  is of a more trenchant character.

There are some words of which the writing is exceptional, due to causes which may sometimes be traced. Thus  , which should according to rule be transcribed *senkti*, was a variant of *seti*. The syllabic , *seti*,

received as hieratic abbreviation , the last line being exactly like the , , of that time: thus it resembles the hieratic group for the three letters , and the scribes took occasion to trace  in hieroglyphics for *set*. This is an imitation of the cursive style taken into the monumental, of which there are a certain number of cases.

SECRET WRITING.

Intentionally accumulated exceptions in certain texts compose what Champollion has called the Secret Writing. The most ancient traces we have found are of the Eighteenth Dynasty. In this system we remark—(1) objects rare or unused in ordinary writing; (2) syllabic signs used as simple letters; (3) phonetic values obtained by turning the signs from their ordinary ideographic values; (4) variants between the values of neighbouring sounds. Thus every deviation was made from the usual principles of writing by which it was possible to produce exceptions. This is an enigmatic system intended to be unintelligible to the ordinary reader. The causes of this method are of interest, for from them originated the new values which strangely complicate the hieroglyphic writing of the time of the Greeks and Romans (the secret writing thus passing in a certain degree into the common writing).

THE USE OF HIEROGLYPHICS IN GRAMMAR.

Although, as already stated, an outline of ancient Egyptian grammar is not given in this article, it is necessary to explain how hieroglyphics were used for grammatical purposes.

In expressing roots or derivatives, whether pronominal, verbal, or of particles, both phonetic and ideographic signs could be employed, either apart or in combination. There is, however, in all but verbal roots a marked preference for phonetic expression, with again a preferential use of alphabetic signs.

The masculine and feminine of nouns are marked, especially when they were ideographically written, by  and : the former was not pronounced; it is doubtful whether the latter was, and if so in what cases (De Rougé, *Chrestomathie*, ii. 7, 8).

The plural of nouns, pronouns, and the pronominal affixes which were also used to indicate the persons of verbs, is indicated by the abstract symbol,   . In the case of nouns it may be replaced by a phonetic

ending or the trebling of the word when written ideographically or even phonetically. The principle of expressing the dual, which is proper to nouns, appears to have been the same, though as to this there are difficulties.

The pronouns and cognate words, including the article, are mostly written alphabetically. The affixed personal pronouns, which are identical in form with a very few exceptions, whether used as possessives, as inflexional verbal suffixes, or as direct complements, or in other words, in their genitive, subjective, and objective uses, afford instructive instances of the different modes of writing. It may be observed that in Egyptian these are the primitive forms of the personal pronouns. The following table is taken from M. de Rougé's *Chrestomathie*, ii. 42, with the omission of some late forms.

AFFIXED PERSONAL PRONOUNS.

Singular.

- 1. *u, a*      
- ku, kua*      
- 2. *m, k* 
- f, t*   

Plural.

It will be remarked that all the phonetic forms but one are written with alphabetic signs, that the introduction of ideographs, either as determinatives or independent symbols, gives the common first person singular a feminine in writing but not in sound, and farther confuses this feminine and the true feminine of the second person singular when represented by the same symbol only. The principle of writing an ideograph to determine the use of the pronoun, phonetically expressed or only represented by that symbol, is carried farther in the first person singular than the table shows, there being special signs for a god, &c.

In the case of the articles and the pronouns of more common use alphabetical signs are employed with ideographic signs for the pronouns when the necessity occurs. Syllabic signs are used for some of the less common pronouns, and ideographs for substantives employed as pronouns. The fuller forms of pronouns are produced by alphabetic signs; the same is usually the case with the compounds that introduce no new element.

The verbal root, identical with that of the noun, is expressed in every mode in which hieroglyphics can be used. It is, however, otherwise with the derivative forms, the inflexions, and the substantive verb, which in its various expressions is really an inflexional word employed in tense-formation. The derivative forms are produced by prefixes which are always alphabetic or by repetition of the radicals (reduplication, sometimes afterwards apocoped). The inflexions are formed by the pronominal affixes for the persons and other prefixes and affixes, these affixes being almost always placed before the pronominal ones, for the moods and tenses; here again the expression is alphabetic with the exceptions afforded by the pronominal affixes as already shewn. The

forms of the substantive verb are phonetic, either alphabetic,                 

 , pu, rarely   , pa,   , pui,  , ar;                   

with the Arabic Koofee in its earliest, which is of course absurd, it would be possible, by selecting the demotic variety nearest in form to the typical Koofee of coin-inscriptions, to shew a very good apparent agreement of many letters. Any one may try the experiment with the Koofee alphabet in Soret's *Numismatique Musulmane*, Pl. I. and M. de Rougé's demotic in the *Chrestomathic* (l.c.); taking care to use only one type where it was repeated by the Arabs for other letters, and in the case of their alphabet to compare only the isolated or final forms. The result would shew the great caution needed in the inquiry.

There are two objections to the proposed derivation of the Phœnician alphabet which must have great weight against any but the strongest evidence of resemblance. The Egyptian letters represent objects the names of which begin with these letters; similarly the Phœnician letters had names indicating an origin from a hieroglyphic system on the same principle of acrophony. It would be supposed if the Phœnician letters were derived from the Egyptian ones that their names would describe the original signs. This, however, is not the case in a single instance. Aleph signifies an ox and not an eagle, Beth a house and not a bird, Gimel a camel and not a basket, and so, as far as we know, to the end. It is difficult to imagine the complete loss of the original form, and the naming of letters from a supposed resemblance to another form, which form can scarcely be traced in the most archaic Phœnician. Yet, if the derivation from hieratic be true, we are tied to this archaic form on account of its apparent similarity to the hieratic, and any deviation to explain the Semitic names of the letters would weaken, if not destroy, the foundation of the theory.

Again, it is very noteworthy that the oldest monuments of the Phœnician alphabet are to be found not in Egypt but in Palestine and Assyria. These are the Stele of Mesha, king of Moab, and the inscriptions on the Nemrod bronze lion-weights. These weights take us a step farther in the argument, for they shew us on official documents of a palace of Assyrian kings the use of this alphabet, side by side with the Assyrian character, as a kind of demotic or perhaps commercial writing, of necessity well-known in Assyria itself. Of course it is not to be supposed that the languages expressed were the same, but they were so closely allied that their joint use in Assyria was natural, and particularly to a nation accustomed to the Turanian Akkadian. This appearance of the Phœnician alphabet in Assyria would suggest that it had its origin rather from Assyrian than Egyptian writing. Is there, however, any evidence that any such alphabet was derived from cuneiform?

Among the systems of writing which present a sufficient similarity to the Phœnician, and its descendant the Greek, to justify our conjecturing their common derivation, though not necessarily their later connexion, is the Cyprian. This is radically different from the Phœnician in being syllabic, and thus having a much larger list of characters, but the formal resemblances suggest the same source. In the case of the Cyprian, Dr. Deecke has endeavoured to shew the source to be the Assyrian cuneiform in its later form. His arguments are very strong; here it is only necessary to mention the syllabic character of the Cyprian, the agreement in form of many signs, without the readjustment of their elements suggested as theoretically possible by the Median and Armenian variants, and the striking fact that the Cyprian is found in two inscriptions written in cuneiform, each stroke having the Assyrian typical shape (Deecke, *Der Ursprung der Kyprischen Sylbenschrift*, Straßburg, 1877).

This probable solution of the Cyprian problem suggested to Dr. Deecke the comparison of the Phœnician alphabet with Mesopotamian cuneiform. The result, published in the *Zeitschrift der Deutschen Morgenländischen Gesellschaft* (xxxi. 102 seqq.), is well worthy the attention of scholars. The inquiry was founded on the comparison of forms and sounds in cuneiform. The forms were much less numerous than the extent of the list of signs would lead us to expect, for the great majority of these signs are far too complex to have been the prototypes of such simple signs as the Phœnician letters. The sounds on the same side present no little difficulty, as the adoption by the Babylonians and Assyrians of the Akkadian system of writing produces a confusion of kindred sounds, and excludes some proper to the Semitic alphabets. A further difficulty arises from the polyphony of the Assyro-Babylonian cuneiform signs, whether ideographic or syllabic, which gives a variety of sounds to the same group and thus greatly diminishes the degree of probability in an agreement. These signs are all conventional transcriptions of original hieroglyphics. These hieroglyphics can sometimes be traced in the rare hieratic forms, and even occasionally in the regular cuneiform types. When we know the original form we can sometimes select the radical sound, but where we find more than one cognate sense with a different sound, the selection becomes difficult, if not impossible. Supposing such a sign to be represented by the English figure 1, standing for "one" and "first," the discovery of the radical sound would be apparently hopeless. It would be obviously so if the sign also stood for "beginning" and "union." The result seems satisfactory to the extent of about one-third of the Phœnician alphabet, signs like the Phœnician having like sounds. This result would have little force did it not seem to be supported by the meaning of some of the signs as compared with the names of the Hebrew letters of which we know the meaning, seventeen in number. But the difficulty in discovering the original radical sound and sense in cuneiform shakes this conclusion. Consequently the five agreements which might be accepted were we certain of the original Assyrian sound and sense cease to have much weight. There are also some probable agreements which, of course, have still less strength. It is, however, to be noted that the syllable *had*, &c., taken as the origin of Heth, and *tip*, as that of Teth, have forms in the hieratic cuneiform agreeable to the meaning of the words from which these syllables are supposed to be abbreviated, *hattu*, a "graver," and *dibbu*, a "writing-table." This explanation of the signs Heth and Teth, consecutive, be it remembered, and without certain renderings, in the Hebrew alphabet, is very remarkable as a confirmation of the theory. For the present it is no more than a theory, but perhaps it is as probable as the derivation of the Phœnician alphabet from Egyptian hieroglyphics, through the hieratic types.

It is of course possible that the old Semitic alphabet had an origin independent of Egyptian hieroglyphics or the conventional hieratic forms of Assyro-Babylonian cuneiform. The discovery of a new hieroglyphic character in the Hittite inscriptions, containing, in a list of greater extent, certain of the forms indicated by the names of the Hebrew letters, is a new factor in the problem, and must be defined before its true value can be ascertained. All that can be said at present is that the Hittite characters wear the aspect of an Egyptian origin. Considering the geographical position of this mode of writing, its *prima facie* evidence is in favour of M. de Rougé's derivation of the Phœnician alphabet from Egyptian.

BIBLIOGRAPHY.

The following list is an outline of the bibliography of the subject:—

DICTIONARIES.—Brugsch, Dr H., *Hieroglyphisch-Ägyptisches Wörterbuch*, the fullest and best Ancient Egyptian Lexicon; Birch, Dr S., "Dictionary of Hieroglyphics" in Bunsen's *Egypt's Place*, vol. v.; Pierret, P., *Vocabulaire Hiéroglyphique*; Champollion, le Jeune, *Dictionnaire Égyptien* now out of date, but valuable for the history of interpretation; vocabularies in various works, as Chabas, F., *Papyrus Magique Harris*, and *Zeitschrift für Ägyptische Sprache und Alterthumskunde*.

SPECIAL DICTIONARIES.—Brugsch, H., *Dictionnaire Géographique de l'Antienne Égypte*; Pierret, P., *Dictionnaire d'Archéologie Égyptienne*; Lieblein, J., *Dictionnaire des noms (propres) hiéroglyphiques*.

GRAMMARS.—Rougé, Vieomte de, *Chrestomathie Égyptienne*, Abrégé Grammatical, complete except as to the particles, the best Egyptian grammar; Brugsch, H., *Grammaire Hiéroglyphique* (Hieroglyphische Grammatik), only second to De Rougé's, and complete; Kossl, F., *Grammatica Copto-Gerogifca*, a useful work, based on Peyron's *Grammatica Lingue Coptica*, and De Rougé's *Chrestomathie Égyptienne*, combining the elements of Hieroglyphics and Coptic; Birch, S., "Hieroglyphic Grammar," in Bunsen's *Egypt's Place*, vol. v.; Le Page Renouf, *Elementary Grammar of Ancient Egyptian*, with Dr Birch's *Egyptian Texts* (Archaic Classes). These two works are the best grammar and reading book for beginners; Champollion, *Grammaire Égyptienne*, out of date, but valuable for history of interpretation.

TEXTS.—Lepsius, Dr H., *Denkmäler aus Ägypten und Aethiopien*, the great corpus of Egyptian transcriptions, without commentary or translation. Many of the most interesting texts are translated in the works of other scholars. Rosellini, I., *I Monumenti dell' Egitto e della Nubia*; *Monumenti Storici*; *Monumenti del Culto*; *Monumenti Civili*; this smaller work contains some texts, particularly the historical inscriptions of Ramses III. (called by Rosellini Ramses IV.), which are not in Lepsius's *Denkmäler*; Champollion, le Jeune, *Monuments de l'Égypte et de la Nubie*, a similar work similarly useful. The "Notices Descriptives" are specially interesting. Of generally later date than the *Denkmäler* are the works of Aug. Mariette (*Choix de Monuments du Sérapéum*; *Abydos*, *Description et Fautes*; *Dendérah*; *Monuments divers recueillis en Égypte et en Nubie*; *Deir el Bahari*; *Les listes géographiques des Pyramides de Karnak*), and of H. Brugsch (*Ösographische Inschriften altägyptischen Denkmäler*; *Recueil des Monuments Égyptiens*; *Monuments géographiques*; *Monuments de l'Égypte*); Dümichen, J., *Die Flotte einer Ägyptischen Königin*; Greene, J. B., *Fouilles à Thèbes*; Rougé, Vic. J. de, *Inscriptions Hiéroglyphiques copiées en Égypte pendant la Mission Scientifique du Vic. E. de Rougé* (*Études Égyptologiques*); Bergmann,

E. von, *Hieroglyphische Inschriften*; Brugsch, H., *Inschrift von Rosetta*; Lepsius, R., *Das Bilingue Dekret von Kanopus*; Reimisch, L., and Roessler, H., *Die zweisprachige Inschrift von Tanis*; Pierret, P., *Glossaire Égyptien-Grec du Décret de Canope* (*Études Égyptol.*); Lepsius, R., *Auswahl der wichtigsten Urkunden des Ägyptischen Alterthums*; Pierret, P., *Recueil des Inscriptions Inédites du Louvre* &c. &c.

TEXTS OF THE RITUAL AND COGNATE WORKS.—Lepsius, R., *Tödtbuch der Ägypten*, and *Älteste Text des Tödtbuchs*; Rougé, E. de, *Rituel Funéraire*; Leemans, C., *Papyrus Égyptiens Funéraires hiéroglyphiques*; H. hiéroglyphiques; Guileysse, P., *Rituel funéraire Égyptien*, chap. 64, textes comparés, traduction, et commentaire; Renouf, Le Page, *Traduction d'un chapitre du rituel funéraire* (a prayer from the Egyptian Ritual); Lefébure, E., *Le Mythe Osirien* (I. Les Yeux d'Horus; II. Osiris; Et. Eg.); Lefébure et Guileysse, *Le Papyrus funéraire de Soutimes*; Pierret, P. (Deveria, T.), *Papyrus de Neb-qed*; Pierret, P., *Manuscrits Religieux* (Et. Eg.), and *Recueil d'Inscriptions Inédites du Louvre* (Le Livre de ce qui est dans l'Hémisphère Inférieur, M. Deveria's translation, &c., Et. Eg.); Lanzoni, R. V., *Le Domicile des Esprits*; Birch, S., *Papyrus of Nas-Aven*; Naville, E., *La Litanie du Soleil*; *Textes relatifs au mythe d'Horus, Edjou*; Brugsch, H., *Sat an Siasin*; Chabas, F., *Papyrus Magique Harris*.

HISTORICAL PAPYRI, &c.—Birch, S., *Select Papyri in the Hieratic Character*, *British Museum*; *Inscriptions in the Hieratic and Demotic Character*, *British Museum*; *Hieratic Papyrus of Ramses III.*, *British Museum*; Eisenlohr, A., *Die grasse Papyrus Harris*; Prisse, E., *Facsimile d'un Papyrus*; Chabas, F., *Les Papyrus Hiéroglyphiques de Berlin*; *Voyage d'un Égyptien*; *L'Égyptologie*, L. Les Maximes du scribe Anu; Eisenlohr, A., *Ein mathematisches Handbuch der alten Ägypten*; Lhncke, A., *Correspondenzen aus der Zeit der Ramessiden*; Lieblein, J., *Deux Papyrus Hiéroglyphiques au Musée de Turin*; Maspero, G., *Études Égyptiennes*, *Romans et Poésies du Papyrus Harris*, No. 600; Mariette, A., *Les Papyrus Égyptiens du Musée de Boulaq*; Pleyte, W. et Rossi, *Papyrus de Turin*; Wiedemann, *Hiératische Texte aus dem Museum zu Leyden und Paris*; Ebers, G., *Das hermetische Buch über die Arzneimittel der alten Ägypter*.

DEMOTIC.—Brugsch, H., *Grammaire Démotique*, and *Hiéroglyphisch-Démotisches Wörterbuch*; Leemans, C., *Papyrus Égyptiques Démotiques à Transcriptions Oreeques*; Revillout, E., *Le Roman de Setna*.

TRANSLATIONS.—Birch, S. (editor), *Records of the Past*; Chabas (ed.), *Mélanges Égyptologiques*; Lepsius, R., Brugsch, H. (edd.), *Zeitschrift für Ägyptische Sprache und Alterthumskunde*.

It is obviously impossible to specify the many valuable translations and dissertations which have been produced by Dr Birch, Dr Brugsch, M. Chabas, Dr Dümichen, M. Deveria, Dr Lepsius, M. Mariette, M. Maspero, M. Pierret, M. E. de Rougé, and other scholars. Many of these works contain Ancient Egyptian texts either in part or entire. (R. S. P.)

HIERONYMITES, HIERONYMIANI, or SANCTI HIERONYMI EREMITÆ, an order of monks, originally hermits, who resolved to adopt the cenobite life under the patronage of St Jerome and the rule of St Augustine. The order first arose in the 14th century in the neighbourhood of Toledo, through the influence of a Franciscan Tertiary named Vasco, and Fernando Pecha, chamberlain of Pedro the Cruel. It soon received papal sanction (from Gregory XI. in 1373), and made considerable progress in Spain and Portugal, where its chief seats were at Guadalupe and Yuste (both in Cáceres, the latter being the scene of the cloister-life of Charles V.), and at the Escorial, the palace-monastery of Philip II. near Madrid; afterwards it gained a footing in America also. From about the close of the 16th century it rapidly decayed, and now it is wholly extinct. The dress of the order consisted of a coarse white frock with tan-coloured scapulary and cowl. About 1375 an order of nuns of St Jerome was originated by Maria Garcias de Toledo, and for a time was highly popular. As branches of the Hieronymite order must be reckoned the Congregation of the Eremites of St Jerome of the Observance, which, originated by Lupus Olivetus, third general of the Hieronymites, was sanctioned by Martin V. in 1426, and still subsists in some parts of Italy as the Congregation of St Jerome of Lombardy, and the Pauperes-Eremitæ Sancti Hieronymi, a congregation founded by Peter of Pisa in 1377, which obtained some foothold in Tyrol and Bavaria, as well as in Italy, and subsisted until 1688. See Reinkeus, *Die Einsiedler des heiligen Hieronymus*, Schaffh., 1864.

HIGDON, or HIGDEN, RANULF, was a Benedictine monk of the monastery of St Werberg in Chester, in which he lived, it is said, for sixty-four years, and died "in a good old age," probably in the year 1363. He was buried, we are told in a note prefixed in the 16th century to the MS. of his work belonging to the library of Christ Church, Oxford, "in St Werberg's Church (now Chester Cathedral), on the south side of the church near the choir, not far from the door which leads into the churchyard; an arch was made for him in the wall, and on the wall is the inscription, "Non hic sub muro, sed subter marmore duro." This monument, extant in the 16th century, seems now to have

entirely disappeared. Higdon was the author of a long chronicle, one of several such works based on a plan taken from Scripture, and written for the amusement and instruction of the society to which the compiler belonged. Its chief interest perhaps lies in the fact that it closes the long series of general chronicles, which were soon put completely out of date by the invention of printing. It is commonly styled the *Polychronicon*, from the longer title *Ranulphi Castronsis, cognomine Higdon, Polychronicon (sive Historia Polycratia) ab initio mundi usque ad mortem regis Edwardi III. in septem libros dispositum*. The work is divided into seven books, in humble imitation of the seven days of Genesis, and, with exception of the last book, is a summary of general history, a compilation made with considerable style and taste. It seems to have enjoyed no little popularity in the fifteenth century. The Christ Church MS. says that Higdon wrote it down to the year 1342; the fine MS. at Christ's College, Cambridge, states that he wrote to the year 1344, after which date, with the omission of two years, John of Malvern, a monk of Worcester, carried the history on to 1357, at which date it ends. According, however, to its latest editor, Higdon's part of the work goes no further than 1326 or 1327 at latest, after which time it was carried on by two continuators to the end. Gale in his *Quindecim Scriptores* published that portion of it, in the original Latin, which comes down to 1066; an English translation of the whole was made by John of Trevisa, and printed by Caxton at his press in Westminster in 1482, with the addition of an eighth book. There is also an anonymous English translation of the work. The whole is being at this time carefully edited by Professor Lumby, B.D., under the authority of the Master of the Rolls; six volumes have appeared, 1865-1876.

HIGHGATE, a suburb of London, county of Middlesex, is situated on an eminence on the great north road, $5\frac{1}{2}$ miles N.W. of the London general post-office. From various points on the hill, which reaches a height of 426 feet, striking views are obtained of London and its suburbs. The village is composed chiefly of a good class of houses surrounded by villas and gardens; and there are a number of mansions of historical interest in the neighbourhood,

among which may be mentioned Arundel House, in which Bacon died in 1626, and Lauderdale House, once the residence of Lord Lauderdale, one of the "Cabals" of Charles II., now used as the convalescent home of St Bartholomew hospital. The principal buildings are the church of St Michael, erected in 1832, in the Perpendicular style, containing a monument to Coleridge, who had his residence in Highgate for nineteen years; the new building erected in 1868 for the grammar school founded by Chief-Justice Cholmeley in the time of Elizabeth; the Roman Catholic monastery called St Joseph's Retreat, a splendid and spacious structure in the Italian style, recently erected; the London diocesan penitentiary, the infirmary, the small-pox and vaccination hospital, the Alexandra orphanage, and the Whittington almshouses. Near the foot of the hill is the Whittington stone, erected in 1821 in place of the old one, which was removed in 1795. In 1809 a scheme was projected to avoid the steep ascent at Highgate by means of an arched tunnel, but after the work had proceeded about 130 yards the whole fell in on 13th April 1812. A road was, however, formed in the line of the intended tunnel, passing under an arch over which the ancient road, Hornsey Lane, is continued. The North London cemetery, in the neighbourhood, contains the graves and monuments of a great number of celebrities. Highgate is supposed by some to have received its name from the gate erected by the bishop of London for the purpose of receiving toll from the passengers by the road which at this point entered his park; but it is possible that gate is here used according to its old signification, and that the name simply means high road. The road was constructed in the 14th century, and the toll-house was built on the site of an ancient hermitage. In the time of stage coaches a custom was introduced of making ignorant persons believe that they required to be sworn and admitted to the freedom of the Highgate before being allowed to pass the gate, the fine of admission being a bottle of wine, which was discussed at the conclusion of the ceremony. The population of the parish in 1871 was 6437, and of the township 5331.

HIGH PLACE is the rendering invariably given in the authorized English version of the Old Testament Scriptures to a Hebrew word הַרְבֵּי of uncertain derivation but with much plausibility connected by Gesenius with the Indo-Germanic root which appears in the Persian *bam* (roof, summit), and in the Greek *βαμός* (compare *βήμα*, Doric *βάμα*). By the LXX. the word is sometimes left untouched (*βαμά* in 1 Sam. ix. 13 and elsewhere); the prevalent rendering of the plural, when a translation is hazarded at all, is in the Pentateuch *στήλαι*, in the historical books *τὰ ὑψηλά, τὰ ὑψη,* and in the prophetic writings *βωμοί*. The Vulgate invariably gives either *excelsa* or *fana*. The habit so widely diffused among primitive peoples of selecting the tops of mountains, or at least elevated sites, as suitable from their comparative isolation from the world and their supposed nearness to the sky for the erection of altars and sacred pillars, is so obviously natural as to require no explanation. Along with that of worshipping under trees or groves (see GROVE), it was fully participated in by the Israelites from an early period, and continued to assert itself down to a very late date, as is abundantly shown by the frequency with which *bamah* and other words (*har, gib'ah, ramah*) signifying height occur in connexion with their public and private worship, whether Jehovistic or idolatrous. Thus one of our earliest notices with regard to Abraham after his departure from Haran is that after setting up a sanctuary at Sichem at the oak of Moreh, he "removed unto a mountain on the east of Bethel, and there builded an altar unto the Lord" (Gen. xii. 8). It was on a mountain (Ebal) that the first altar to Jehovah was raised

by Joshua after the conquest of Canaan had begun (Josh. viii. 30; cf. Deut. xxvii. 4, 5); and many other "high places," some of them (*e.g.*, Beth-Shemesh, or Ir-Heres, and Ashtaroth Karnaim) apparently taken over directly from the Canaanites, speedily obtained recognition as sanctuaries. A few of these, such as Shiloh, early became important pilgrimage centres, but this was not regarded as inconsistent with the right of each town or village-community to have its own high place, or with the view that Palestine as a whole was the "house" or peculiar territory of God, and that it was therefore lawful on suitable occasions to erect new and extempore altars or high places within its limits. For example, we find in 1 Sam. x., xi. repeated references made to the *bamah* of Samuel's native village as if it were a thing of course; from 2 Sam. xv. 32 (Hebr.) we gather that even in David's time the top of Mount Olivet was a place "where God was wont to be worshipped;" while at a later period we read of Elijah repairing the altar on Mount Carmel that had been broken down, and complaining of the violation of God's covenant of which those persons had been guilty who had thrown down the altars and slain the prophets (1 Kings xviii. 30; xix. 10, 14). And we read of new altars, generally on high places, being set up by Gideon (Judg. vi. 26, 27), by Manoah (Judg. xiii. 19, 20), and repeatedly by Saul (1 Sam. xiv. 35). The comparatively late author of the books of Kings expressly states, on the one hand, that before the days of Solomon the people "sacrificed in high places because there was no house built unto the name of the Lord" (1 Kings iii. 2), and, on the other hand, that after that king the high places were removed neither by Asa (1 Kings xiv. 15), nor by Jehoshaphat (xxii. 44), Joash (2 Kings xii. 3), Amaziah (xiv. 4), Uzziah (xv. 4), or Jotham (xv. 35). The still later author of the books of Chronicles, indeed, states of Asa (2 Chr. xiv. 5) and Jehoshaphat (xvii. 6) that they did take away the high places "out of all the cities of Judah;" but this apparent contradiction can best be explained if we assume that the chronicler is alluding only to those high places where heathen deities were worshipped or idolatrous practices allowed, while the earlier author had in view the Jehovistic high places which, during many of the earlier reigns at least, were not discountenanced either in the northern or in the southern kingdom. In reading such a passage as Amos vii. 9, it would be a mistake to interpret it as meaning that the multiplicity of *bamoth* was regarded as wrong in itself; the prophet's zeal is directed not against the places but against the cultus and the false value that was attached to it. Hezekiah is the first monarch of whom in the earlier record we read that with some risk to his popularity he removed the high places and altars of Jehovah, and "said to Judah and Jerusalem, ye shall worship before this altar in Jerusalem" (2 Kings xviii. 4 compared with xviii. 22). But it was not until the reign of Josiah that the high places were finally repressed, not on the ground of direct prophetic revelation, but on that of a strict written law. Even then, however, a distinction was made between the "high places" of the southern kingdom, sacred to Jehovah, and those of the northern, dedicated to a mixed worship; the priests of the former were brought to Jerusalem, and, though not allowed to officiate at the altar there, were permitted to share the priests' portion along with their brethren, while those of the latter were put to death (2 Kings xxiii. 8, 20). As for the altars built upon the high places, their construction appears to have been regulated by the law provided for the case in Ex. xx. 24, 25; very often *mayceboth* or pillars were erected beside them (see Ex. xxiv. 4; Josh. xxiv. 26; cf. Isa. xix. 19; Hosea iii. 4); and sometimes they were enclosed in "houses" or "temples" (1 Kings xii. 31, xiii. 32; Amos vii. 13). For the bearing of the facts contained

in this article on the criticism of the Pentateuch and of its legislation, see PENTATEUCH.

HIGHWAYS. A highway is a public road over which all persons have full right of way—walking, riding, or driving. See ROADS. Such roads in England for the most part either are of immemorial antiquity or have been created under the authority of an Act of Parliament. But a private owner may create a highway at common law by dedicating the soil to the use of the public for that purpose; and, apart from any special dedication, the using of a road for a number of years, without interruption, will support the presumption that the soil has been so dedicated, and the road will be to all intents and purposes a public highway. At common law the parish is required to maintain all highways within its bounds; but by special custom the obligation may attach to a particular township or district, and in certain cases the owner of land is bound by the conditions of his holding to keep a highway in repair. Breach of the obligation is treated as a criminal offence, and is prosecuted by indictment. Bridges, on the other hand, and so much of the highway as is immediately connected with them, are as a general rule a charge on the county; and by 22 Henry VIII. c. 5 the obligation of the county is extended to 300 yards of the highway on either side of the bridge. A bridge, like a highway, may be a burden on neighbouring land *ratione tenuræ*. Private owners so burdened may sometimes claim a special toll from passengers, called a "toll traverse."

Extensive changes in the law of highways have been made by the recent Highway Acts, viz., The Highway Act, 1835 (5 and 6 Will. IV. c. 50), and the amending Acts of 1862 and 1864. It is no longer possible for a private owner, by dedicating a highway to the public, to make the charge of maintaining it a burden on the parish in all cases. To create a new highway of this character he must give three months' notice of his intentions to the parish surveyor, and a meeting of vestry must then be called to consider whether the proposed highway is worth the expense of maintenance. Should the vestry decide against it, the charge of maintenance will not fall on the parish, unless the justices of the peace at the next highway sessions decide otherwise.

The leading principle of the Highway Act, 1835, is to place the highways under the direction of parish surveyors, and to provide for the necessary expenses by a rate levied on the occupiers of land. Two or more parishes may unite to form a district under a district surveyor, and large parishes may appoint more than one surveyor. It is the duty of the surveyor to keep the highways in repair; and if a highway is out of repair, the surveyor may be summoned before justices and convicted in a penalty not exceeding £5, and ordered to complete the repairs within a limited time. The surveyor is likewise specially charged with the removal of nuisances on the highway, or any obstruction or injury rendering it less commodious to the public. A highway nuisance may be abated by any person, and may be made the subject of indictment at common law. The Act contains provisions simplifying the process by which a highway may be widened, enlarged, diverted, or stopped. The amending Acts, while not interfering with the operation of the principal Act, authorize the creation of highway districts on a larger scale. The justices of a county may convert it or any portion of it into a highway district to be governed by a highway board, the powers and responsibilities of which will be the same as those of the parish surveyor under the former Act. The board consists of representatives of the various parishes, called "way wardens," together with the justices for the county residing within the district. Salaries and similar expenses incurred

by the board are charged on a district fund to which the several parishes contribute; but each parish remains separately responsible for the expenses of maintaining its own highways.

The Highway Act of 1835 specifies as offences for which the driver of a carriage on the public highway may be punished by a fine, in addition to any civil action that may be brought against him,—riding upon the cart, or upon any horse drawing it, and not having some other person to guide it, unless there be some person driving it; negligence causing damage to person or goods being conveyed on the highway; quitting his cart, or leaving control of the horses, or leaving the cart so as to be an obstruction on the highway; not having the owner's name painted up; refusing to give the same; and not keeping on the left or near side of the road, when meeting any other carriage or horse. This rule does not apply in the case of a carriage meeting a foot-passenger, but a driver is bound to use due care to avoid driving against any person crossing the highway on foot. At the same time a passenger crossing the highway is also bound to use due care in avoiding vehicles, and the mere fact of a driver being on the wrong side of the road would not be evidence of negligence in such a case. When there is a public crossing in a street, the driver is bound to use special care; and the expression has been used that a crossing is the special property of the foot-passengers.

The "rule of the road" given above is peculiar to the United Kingdom. Cooley's treatise on the *American Law of Torts* states that "the custom of the country, in some States enacted into statute law, requires that when teams approach and are about to pass on the highway, each shall keep to the right of the centre of the travelled portion of the road." The same appears to be the general rule on the continent of Europe.

The excessive use of the highway by acts which in moderation are lawful becomes a nuisance if it interferes with the public enjoyment of the roadway. Thus when a carrier, having warehouses on a public street, occupied one side of the street in loading and unloading his waggons several hours at a time, so that foot-passengers were incommoded and no carriage could pass on that side, although there was room for two carriages on the opposite side, this was held to be a nuisance; and Lord Ellenborough held it to be a nuisance for stage coaches to stop in the street for three-quarters of an hour taking up and setting down passengers, for the "king's highway was not to be used as a stable-yard." In the same way, at common law a tramway laid along a highway is a public nuisance, although it may be shown to be a common convenience. The construction of tramways is now authorized by 33 and 34 Vict. c. 78.

The Acts 24 and 25 Vict. c. 70, and 28 and 29 Vict. c. 83, regulate the use of locomotives on turnpike and other roads. No engine, so constructed as to be a public or private nuisance, is protected by these Acts. When horses had been frightened by a traction engine, and the jury found that it was likely to frighten horses and that the defendant knew it, he was held liable in damages.

Turnpike Acts.—Many of the more important highways are placed under the management of boards of commissioners or trustees. The number of local and general turnpike acts is very great. No fewer than thirty-three general acts are mentioned in the index to the statutes—the first and principal Act being 3 Geo. IV. c. 126. The trustees are required and empowered to maintain, repair, and improve the roads committed to their charge, and the expenses of the trust are met by tolls levied on persons using the road. The various grounds of exemption from toll on turnpike roads are all of a public character, e.g., horses and carriages attending the sovereign or royal family, or used by soldiers or volunteers in uniform, are free from toll. In general horses

and carriages used in agricultural work are free from toll. By the Highways and Locomotives Act of 1878 (41 and 42 Vict. c. 77) disturnpiked roads are to become "main roads," and half the expense of maintenance is to be paid out of the county rate. Ordinary highways may be declared to be "main roads," and "main roads" may be reduced to the status of ordinary highways.

In Scotland the highway system will in future be regulated by the Roads and Bridges Act, 1878, which comes into operation at the latest on the 1st of June 1883, but may be adopted sooner in any county. From and after the commencement of the Act in each county, the management and maintenance of the highways and bridges shall be vested in the county road trustees, viz., the commissioners of supply, certain elected trustees representing ratepayers in parishes, and others. One of the consequences of the commencement of the Act is the abolition of tolls, statute-labour, causeway mail, and other exactions for the maintenance of bridges and highways; and all turnpike roads shall become highways, and all highways shall be open to the public free of tolls and other exactions. The county is to be divided into districts under district committees, and county and district officers are to be appointed. The expenses of highway management in each district (or parish), together with a proportion of the general expenses of the Act, shall be levied by the trustees by an assessment on the lands and heritages within the district (or parish).

Highway, in the law of the States of the American Union, generally means a lawful public road, over which all citizens are allowed to pass and repass on foot, on horseback, in carriages, and waggons. Sometimes it is held to be restricted to county roads as opposed to town-ways. In statutes dealing with offences connected with the highway, such as gaming, negligence of carriers, &c., "highway" includes navigable rivers. But in a statute punishing with death robbery on the highway, railways were held not to be included in the term. In one case it has been held that any way is a highway which has been used as such for fifty years. (E. R.)

HILARION, Sr, abbot, the first to introduce the monastic system into Palestine, was born of heathen parents at Tabatha, about 5 miles to the south of Gaza, about the year 288, was sent when very young to Alexandria to be educated, and there became a convert to the Christian religion. Attracted by the fame of St Anthony, he went to visit that saint in his solitude, and forthwith became a disciple. Returning to Palestine with some companions while still but a lad of fifteen, he gave away all the property he had inherited by the recent death of his parents, and then withdrew into loneliness in the desert between the sea and the marshes on the Egyptian border. In this solitude he observed the most rigid asceticism, and (to quote the quaint remark of Butler) "thought himself at liberty to practise certain mortifications which the respect we owe to our neighbour makes unseasonable in the world." Twenty years of patient continuance in the way of life he had chosen for himself were rewarded, we are told, with miraculous gifts and with rapidly growing fame; disciples and imitators multiplied to the number of two or three thousand, and all owned the spiritual oversight of Hilarion. Informed by revelation when sixty-five years old of the death of Anthony, he undertook an extended tour into Egypt, where he visited all the scenes of that saint's labours; afterwards he removed in the company of a favourite disciple, Hesychius, into Sicily, where, however, his popularity rendered impossible the quiet and retirement which were congenial to his habits, a further migration to Epidaurus thus became necessary; and ultimately he found a resting-place in Cyprus, the diocese of his old friend Epiphanius, where in a lonely cell amongst some almost inaccessible

rocks he died in 371. According to Sozomen his festival was observed in Palestine with great solemnity as early as the 5th century; he is now commemorated by the Roman Church on October 21st. His earliest biographers were Epiphanius and Jerome.

HILARIUS, or HILARUS (HILARY), bishop of Rome from 461 to 467, who according to some authorities had attained to the archidiaconate as early as the year 417, is known to have been a deacon and to have acted as legate of Leo the Great at the "robber" synod of Ephesus in 449. There he so vigorously defended the conduct of Flavian in deposing Eutyches that he was thrown into prison, whence he had great difficulty in making his escape to Rome. Chosen to succeed Leo on November 12, 461, he issued a brief *de fide catholica*, in which he anathematized Eutyches, Nestorius, and Dioscurus, and reaffirmed the decisions of the councils of Nice, Ephesus, and Chalcedon. In 465 he held at Rome a council which put a stop to some prevalent abuses, particularly to that of bishops appointing their own successors. His pontificate was also marked by a successful encroachment of the papal authority on the metropolitan rights of the French and Spanish hierarchy, and by a resistance to the toleration edict of Anthemius, which ultimately caused it to be recalled. Hilarius, who died November 17, 467, was succeeded by Simplicius.

HILARIUS, Sr, of Arles (c. 403-449), an eminent prelate and an able if unsuccessful defender of the liberties of the Gallican Church, was born about 403, and in early youth entered the abbey of Lerins, then presided over by his kinsman Honoratus (St Honoré). Having succeeded Honoratus in the bishopric of Arles in 429, he set about the discharge of his episcopal functions with unusual energy and zeal. Following the example of St Augustine, he is said to have organized his cathedral clergy into a "congregation," devoting a great part of their time to social exercises of ascetic religion. As bishop of Arles he held the rank of metropolitan of Vienne and Narbonne, and in this capacity he came into collision in 444 with Leo the Great on the question of the deposition of one of his bishops (Chelidonius); this quarrel resulted in his being deprived of his rights as metropolitan to consecrate bishops, call synods, or exercise ecclesiastical oversight in the province, and in the edict of Valentinian III., so important in the history of the Gallican Church, "ut episcopis Gallicanis omnibusque pro lege esset quidquid apostolicæ sedis auctoritas sanxisset." He died in 449, and his name was afterwards introduced into the Roman martyrology for commemoration on the 5th of May. Hilarius enjoyed during his lifetime a high reputation for learning and eloquence as well as for piety; his extant works (*Vita S. Honorati Arelatensis Episcopi* and *Metrum in Genesin*) compare favourably with any similar literary productions of that period. A poem, *De Providentia*, usually included among the writings of Prosper, is sometimes also attributed to Hilary of Arles.

HILARIUS, Sr, bishop of Pictavium (Poitiers), an eminent "doctor" of the Western Church, sometimes referred to as the "malleus Arianorum" and the "Athanasius of the West," was born at Poitiers about the end of the 3d century A.D. His parents, who were pagans of distinction, afforded him every means of acquiring a good education; and to the ordinary accomplishments of an educated gentleman there was added in his case what had even then become somewhat rare in the West, some knowledge of Greek. After he had attained to manhood his attention was directed to the Old and New Testament writings, with the result that he became convinced of the truth of Christianity, and along with his wife and his daughter received the sacrament of baptism. We have no means of knowing the nature or duration of the services which he rendered the church during the period which im-

mediately followed his admission within its pale; but he appears to have continued to reside in Poitiers, and so great was the respect in which he came to be held by the citizens there that about 353, although still a married man, he was by the unanimous voice elected bishop. At that time Arianism, which under imperial protection had over-spread the Eastern, was now under similar auspices threatening also to overrun the Western Church; to resist and repel the irruption was the great task which Hilary now set himself to achieve. One of his first steps was to secure the excommunication, by those of the Gallican hierarchy who still remained orthodox, of Saturninus, the Arian bishop of Arles, along with Ursacius and Valens, two of the most prominent of the supporters of that prelate. About the same time he wrote to the emperor Constantius a remonstrance against the persecutions by which the Arians had sought to crush their opponents (*Ad Constantium Augustum Liber Primus*, of which the most probable date is 355). His labours for the triumph of orthodoxy were not in the first instance, however, crowned with success; for at the synod of Biterræ (Beziers), summoned in 356 by Constantius with the professed purpose of settling the long-standing disputes, Hilary was by an imperial rescript banished along with Rhodanus of Toulouse to Phrygia, in which exile he spent nearly four years. From this hostile region, however, he continued to govern his diocese without undue difficulty, no successor having been nominated to the see; while at the same time he found leisure for the preparation of two of the most important of his contributions to dogmatic and polemical theology, the *De Synodis*, or *De Fide Orientalium*, an epistle addressed in 358 to the bishops in Gaul, Germany, and Britain, expounding the true views (sometimes veiled in ambiguous words) of the Oriental bishops on the Trinitarian controversy, and the *De Trinitate Libri XII.*, composed in 359 and 360, in which, for the first time, it was successfully attempted to express in the Latin tongue the theological subtleties and refinements which had been elaborated with the aid of the more flexible language of Greece. The former of these works was not entirely approved by some of the members of his own party, who thought he had shown too great forbearance towards the Arians, and had expressed himself too hopefully as to the possibilities of an ultimate reconciliation of the contending views; to their criticisms he replied in the *Apologetica ad Reprehensores Libri de Synodis Responsa*. In 359 Hilary attended the convocation of bishops at Seleucia in Isauria, where, along with the Egyptian Athanasians, he joined the Homoiousian majority against the Arianizing party headed by Acacius of Cæsarea; thence he betook himself to Constantinople, and, in a petition (*Ad Constantium Augustum Liber Secundus*) personally presented to the emperor in 360, repudiated the personal calumnies of his enemies and sought to vindicate his Trinitarian principles. His urgent and repeated request to be permitted a public discussion with his opponents, especially with Ursacius and Valens, proved at last so inconvenient that he was sent back to his diocese, which, accordingly, he appears to have reached about 361, within a very short time of the accession of Julian. Though he was received in his diocese with every demonstration of joy, he yet found Arianism strong enough there to demand his best energy and skill for the next two or three years; but in 364, extending his efforts once more beyond Gaul, he impeached Auxentius, bishop of Milan, and a man high in the imperial favour, as heterodox. Summoned to appear before the emperor (Valentinian) at Milan and there maintain his charges in person, Hilary had the mortification of hearing the supposed heretic give answers entirely satisfactory to all the questions which were proposed; nor did his (doubtless sincere) denunciation of the metropolitan as a hypocrite save himself from an

ignominious expulsion from Milan as a disturber of the peace of the church. In 365 he published the *Contra Arianos vel Auxentium Mediolanensem Liber*, in connexion with the controversy; and also (but perhaps at a somewhat earlier date) the *Contra Constantium Augustum Liber*, in which he pronounced that lately deceased emperor to have been Antichrist, a rebel against God, "a tyrant whose sole object had been to make a gift to the devil of that world for which Christ had suffered." The later years of Hilary's life were spent in comparative quiet and retirement, devoted in part to the preparation of his expositions of the Psalms (*Tractatus super Psalmos*), for which he was largely indebted to Origen; of his *Commentarius in Evangelium Matthæi*, a work of no exegetical value; and of his no longer extant treatise on the book of Job. He died 13th January 368. His great energy and zeal, courage and perseverance, rendered him a very influential ecclesiastic during his life; while, in virtue at once of the depth and acuteness of his intellect and of the wide extent of his knowledge, he holds the very highest rank among the Latin writers of his century. Designated already by Augustine as "the illustrious doctor of the churches," he by his works exerted an increasing influence in later centuries; and by Pius IX. he was formally recognized as "universæ ecclesiæ doctor" at the synod of Bordeaux in 1851. Hilary's day in the Roman calendar is January 14; the English "Hilary Term" begins on the 11th and ends on the 31st.

Of Hilary's works, which include, besides those already mentioned, some minor treatises, there have been several editions, of which the most worthy of mention are that of Erasmus (Basel, 1523, 1526, 1528), the Benedictine by Contant (Paris, 1693; reprinted by Maffei, Verona, 1730), and that of Migne in the *Patrologia Cursus Completus*. His biography by Fortunatus probably dates from about the middle of the 6th century; other sources for the facts of the life of Hilary are the numerous incidental notices to be met with in his own writings and in those of Jerome, Sulpicius Severus, and Gregory of Tours. See Reinkens, *Hilarius v. Poitiers* (1864).

HILDA, or HILD (614–680), usually called St Hilda, a Saxon lady whose name is intimately associated with the history of the early English church and of early English literature. She was a member of the royal family of Northumbria, her father Hereric being a nephew of King Edwin; and it was along with her royal kinsman that, as a girl of fourteen, she received baptism at the hands of Paulinus. During the pagan reaction which followed Edwin's defeat and death, Hilda was tempted to settle with her widowed sister Hereswith at the monastery of Chelles, 12 miles from Paris; but she was recalled to England by Bishop Aidan, the missionary from Iona, and in 649, two years after her consecration as a nun, she was appointed to succeed Heru the abbess of Heortea or Hartlepool. When, in fulfilment of the vow which he had made before the decisive battle with Penda, Oswy came to dedicate his daughter to God, it was to the care of Hilda that he entrusted her. In 658 the abbess founded the famous monastery on the cliffs at Streonshalh or Whitby, and for the next twenty-two years she ruled with rare ability and virtue over the double community of monks and nuns which gathered round her. Among those who shed the most abiding lustre on the establishment were St John of Beverley and the Saxon poet Cædmon. Hilda died, full of years, in 680, mourned by her nuns as their common mother. There is a St Hilda's church both at South Shields and at Hartlepool, and the latter preserves her effigy on its ancient seal. At Whitby the tradition long lingered that on a summer forenoon, when the sun shone in the highest windows of the north part of the abbey, a figure of Lady Hilda could be discerned; and the fossil ammonites of the neighbourhood are popularly known as St Hilda's snakes. See Bede, *Ecc. Hist.*, xxiv.; Dr G. Young, *Hist. of Whitby*, 1817; Sir Cuthbert Sharp, *Hist. of Hartlepool*, 1816.

HILDBURGHAUSEN (in old records *Hiltpershusia* and *Villa Hilperti*), the chief town of a circle in the duchy of Saxe-Meiningen, Germany, is situated in a wide and fruitful valley on the river Werra and on the Werra railway, 19 miles south-east of Meiningen by rail. It is the seat of a circle court, of a court of appeal, and of the jury court for the duchy. The streets are wide and regular, and the principal buildings are the former castle of the duchy, erected 1685-95, now used as barracks, with a park in which there is a monument to Queen Louise of Prussia; the old town-house, the Government buildings, the gymnasium erected in 1877, the normal seminary, and the lunatic asylum. A monument has been erected to those of the citizens who died in the Franco-Prussian War of 1870-71. The manufactures are very various, and include linen fabrics, cloth, papier-mâché, toys, buttons, optical instruments, agricultural machines, knives, mineral waters, condensed soups, and condensed milk. The population in 1875 was 5162.

Hildburghausen belonged in the 14th century to the counts of Henneberg, from whom it passed into the possession of the dukes of Saxony. In 1688 it became the capital of a principality, which in 1826 was united to Saxe-Meiningen.

HILDEBERT (**HYDALBERT**, **GILDEBERT**, **ALDEBERT**) of Le Mans and afterwards of Tours, a prominent church-leader, and one of the best Latin writers of his century, was born about 1055 at Levardin near Vendôme, became a pupil of the famous Berengarius of Tours, and made so great progress in all the learning of the time that he was made head master of the school, archdeacon, and finally, in 1097, bishop of Le Mans. In the beginning of his episcopate much trouble was caused him by the jealousy of his dean, Godfrey, who had accused him of immorality; but finally he succeeded in fully vindicating his innocence. He next had to encounter the persecutions of William Rufus, who had captured the city; and these proved so harassing that he ultimately felt it necessary to withdraw to Rome, with the intention of resigning his charge; but Pope Paschalis II. declined to give him his release. On his return to Le Mans, Hildebert found the diocese in a state of great commotion, which had been caused by the preaching of Henry the Deacon; but he speedily succeeded in restoring order after he had banished the agitator. About 1125 he was translated, much against his will, to the see of Tours; and soon afterwards he held the important synod of Nantes, convened for the purpose of correcting the abuses and terminating the disorder which had so long prevailed in Brittany. A dispute with Louis the Fat about the rights of ecclesiastical patronage brought him into much disfavour with that monarch; but their mutual relations had much improved before the death of Hildebert, which took place on December 18, 1134. From some writers he has received the name of Saint, but his name occurs in no martyrology.

The works of Hildebert, which include letters, sermons, and poems, as well as formal contributions to philosophy and dogmatic theology, have been edited by Beaugendre (Paris, 1708), and in part both by Baluze and Muratori. (See also Galland's *Bibliotheca Patrum*, vol. xiv.) The poems, which are on very various subjects, are disfigured by many faults of metre and defects of style, but nevertheless enjoyed great popularity in their time, and were frequently used as classics in the schools of France and Italy, as also were the letters, of which the literary merit is greater (129 in 3 books). The sermons are often eloquent and instructive, but generally overloaded with imagery and disfigured by an excessive use of the allegorical method of interpretation. The tendency to Mariolatry is strongly developed in them; and the *De Cæna Domini* has an historical interest, as exhibiting the first instance of the use of the word transubstantiation. The *Tractatus de querimonia s. conflictu carnis et animæ* is an imitation of Boetius; and the *Moralis Philosophia* has its sources in earlier Latin authors, and especially in Cicero and Seneca. The *Tractatus theologicus* appears to have determined the form of later systems, and thus to be of importance in the history of dogmatic theology. His method is first to

lay down the thesis, which is then supported by scripture proofs and by passages from the fathers, especially from Augustine; he finally proceeds by detailed argument to dispose of difficulties and objections with considerable acuteness, and without that excessive subtlety which characterized later scholastic writers.

HILDEBRAND. See GREGORY VII.

HILDEBRANDSLIED. This invaluable example of Old German alliterative poetry is contained in a MS. originally belonging to the library of Fulda, and now preserved at Cassel. It is written on the first and last pages of a volume of Biblical and theological contents by two contemporary hands apparently belonging to the beginning of the 9th century. The conclusion of the poem is unfortunately wanting, evidently from want of space. From such misreadings as *man for inan*, and *puas for was or was* (with *p* for the Runic *w* sign sometimes used here as in Old English MSS.), it is manifest that our text was not written down from memory,—as has often been assumed,—but is a transcript from an older original. This conclusion is confirmed by the state of the language of the fragment, which shows a curious mixture of Low and High German forms that can never have existed in any living dialect of Germany, but can only be explained as the result of an attempt made by a Low German scribe to adapt the forms of a High German original to his vernacular idiom.

The fragment is mostly taken up with a dialogue between Hildebrand and his son Hadubrand. When Hildebrand followed his master Theodorich the Great, exiled from Italy by Odoacer, he left his young wife and an infant child behind him. At his return to his old home, after thirty years' absence at the Hunnic court, he is met by a young warrior and challenged to single combat. Before the fight begins, Hildebrand, asking for the name of his opponent, and discovering his own son in him, tries to avert the fight, but in vain. "Then they let their horses run with their sharp spears, and then they hewed their white shields until they were beaten to pieces with their weapons." With these words the fragment stops abruptly, giving no clue as to the issue of the combat. It is certain, however, from allusions to the tale made in the Old Norse Asmundar Saga, that it must have been fatal to Hadubrand.¹ But in the later traditions both of the Old Norse Thidriks Saga (13th century), and the so-called *Jüngere Hildebrandslied*,—a German popular song preserved in several versions dating from the 15th to the 17th century, but evidently originating at an earlier time,²—Hadubrand is represented as defeated simply, and obliged to recognize his father.

The *Hildebrandslied* was discovered and published for the first time as a prose story, as early as 1729;³ but it was not till 1812 that its metrical character was recognized by the brothers Grimm.⁴ Since that time numerous reprints and critical editions have been published, among which Lachmann's text⁵ holds the foremost rank as to critical exactness and sagacity, although some of the metrical rules laid down by Lachmann, and followed in his text, have since been shown not to be applicable to the Old German alliterative verse in which the *Hildebrandslied* is written.⁶

HILDEBRANDT, **EDUARD** (1817-1868), was born in 1817, and served his term as apprentice to his father, a house-painter at Dantzic. He was not twenty when he came to Berlin, where he was taken in hand by Wilhelm

Krause, a painter of sea-pieces. Like other artists who have earned a name for subtle and rapid execution, he worked at first in a formal, smooth, and timid fashion. Several early pieces exhibited after his death,—a breakwater, dated 1838, ships in a breeze off Swinemünde (1840), and other canvases of this and the following year,—show Hildebrandt to have been a careful student of nature, with inborn talents kept down by the conventionalisms of the formal school to which Krause belonged. It is difficult to say what the outcome of his art would have been if Hildebrandt had not felt other influences than those of his native schools. Accident made him acquainted with masterpieces of French art displayed at the periodical exhibitions of the Berlin Academy, and these awakened his curiosity and envy. He made up his bundle and wandered to Paris, where, about 1842, he entered the atelier of Isabey and became the companion of Lepoittevin. In a short time he sent home pictures which might have been taken for copies from these artists. Gradually he mastered the tricks of touch and the mysterious secrets of effect in which the French at this period were already so perfect. He also acquired the necessary skill in painting figures, and having done this he returned to Germany, unsurpassable in technical execution, and well skilled in the rendering of many kinds of landscape forms. His pictures of French street life, done about 1843, are impressed with the stamp of the Paris school, but they reveal at the same time a spirit eager for novelty, quick at grasping, equally quick at rendering, momentary changes of tone and atmosphere in varying space and medium. After 1843 Hildebrandt, under the influence of Humboldt, extended his travels, and in 1864–65 he actually went round the world. But whilst his experience became enlarged his powers of concentration broke down. He lost the taste for detail in seeking for scenic breadth, and a fatal facility of hand diminished the value of his works for all those who look for composition and harmony of hue as necessary concomitants of tone and touch. In oil he gradually produced less, in water colours more, than at first, and his fame will probably rest on the sketches which he made in the latter form, many of which are known to the general public by means of chromo-lithography. His course may best be compared to that of a meteor, being breathlessly rapid, brilliant, and charged with colour. No other had the same art of combining elements singly unpicturesque into a picturesque and striking whole, and this chiefly by contrasts of tint and observation of natural phenomena. Fantasies in red, yellow, and opal, sunset, sunrise, and moonshine, distances of hundreds of miles like those of the Andes and the Himalaya, narrow streets in the bazaars of Cairo or Suez, panoramas as seen from mastsheads, wide cities like Bombay or Peking, narrow strips of desert with measureless expanses of sky,—all alike display the *bravura* of a master who had innumerable admirers in his day on account of this facility, and deserved all the admiration he received, subject to the merited reproach that all these fireworks would have been more satisfactory if combined with deeper meditation on the art of composition and more patient study of detail. Hildebrandt died young at Berlin, on the 25th of October 1868. His pictures are scattered in vast numbers throughout Germany. But good selections are accessible in the royal palaces and in the collections of Borsig, Raabe, and Ravené at Berlin.

HILDEBRANDT, THEODOR (born at Stettin 1804, died at Düsseldorf 1874), was a disciple of the painter Schadow, and, on Schadow's appointment to the presidency of a new academy in the Rhenish provinces in 1828, followed that master to Düsseldorf. Bred in the academy of Berlin, and finished under Schadow (1820–24), Hildebrandt began by painting pictures illustrative of Goethe and Shakespeare; but in this form he followed the traditions of the stage

rather than the laws of nature. His artificial modes of thought were not, however, without admirers, and he produced rapidly Faust and Mephistopheles (1824), Faust and Margaret (1825), and Lear and Cordelia (1828). He visited the Netherlands with Schadow in 1829, and wandered alone in 1830 to Italy; but travel did not alter his style, though it led him to cultivate alternately eclecticism and realism. At Düsseldorf, about the year 1830, he produced Romeo and Juliet, Tancred and Clorinda, and other works of the same kind which deserved to be classed with earlier ones; but during the same period he exhibited (1829) the Robber and (1832) the Captain and his Infant Son, examples of an affected but kindly realism which captivated the public of the time, and marked to a certain extent an epoch in Prussian art. The picture which made Hildebrandt's fame is the Murder of the Children of King Edward, of which the original, afterwards frequently copied, still belongs to the Spiegel collection at Halberstadt. It challenges comparison with a similar composition by Paul Delaroche, though rather to Hildebrandt's disadvantage. Hildebrandt chose the moment when the children are asleep, and the murderers pause ere they smother their victims with a pillow. Delaroche with subtler sense of artistic propriety represented the princes seated on their bed, unconscious of the near approach of their assassins, whose vicinity is betrayed by a streak of light at the bottom of the door and the wailing of a dog. The execution of Delaroche is spirited and delicate, that of Hildebrandt finished and smooth. But the German master, who was below Sohn and Schadow in power, is also naturally far below his French competitor. Comparatively late in life Hildebrandt tried his powers as an historical painter in pictures representing Wolsey and Henry VIII., but he lapsed again into the romantic in Othello and Desdemona, a fair replica of which, in Schulte's collection at Düsseldorf, gives a good idea of his shiny, ineffectivo, technical execution. After 1847 Hildebrandt gave himself up to portrait painting, and in that branch succeeded in obtaining a large practice.

HILDEGARD (1098–1179), commonly referred to as St Hildegard, abbess, "prophetess," and a figure of some consequence in the history of mediæval mysticism, was born of noble parents at Bockenheim in the countship of Sponheim, diocese of Mainz, in 1098 (or 1099), and from her eighth year was educated at the Benedictine cloister of Disibodenberg (Mons Disibodi) in the principality of Zweibrücken, now in Rhenish Bavaria, where Jutta, sister of the count of Sponheim, was at that time abbess. From earliest childhood, we learn from Hildegard herself, she was accustomed to see visions which increased in frequency and vividness as she approached the age of womanhood; these, however, she for many years, though with great pain, kept almost wholly secret, nor was it until she had reached her forty-third year (1141) that she felt constrained at last to divulge them. Committed to writing by her intimate friend the monk Godefridus, they now form the first and most important of her printed works, entitled *Scivias* (probably an abbreviation for "sciens vias" or "nosce vias Domini") s. *Visionum et Revelationum Libri III.*, and completed in 1151. In 1147 St Bernard of Clairvaux, having come to Bingen while engaged in preaching the new crusade throughout Germany, chanced to hear of Hildegard's revelations, and on inquiry became so convinced of their reality that he not only wrote to her a letter cordially acknowledging her as a prophetess of God, but also successfully advocated her recognition as such by his friend and former pupil Pope Eugenius III. in the synod of Trèves (1148). In the same year Hildegard, who meanwhile had succeeded Jutta as abbess at Disibodenberg, and had attracted overflowing numbers to that

cloister, migrated along with eighteen of her nuns to a new convent at Rupertsberg near Bingen, over which she presided during the remainder of her life. By means of voluminous correspondence, as well as by extensive journeys, in the course of which she was unwearied in the exercise of her gift of prophecy, she wielded for many years an increasing influence upon her contemporaries,—an influence doubtless due to the fact that she herself was so fully imbued with the most widely diffused feelings and beliefs, fears and hopes, of her time. Amongst her correspondents were Popes Anastasius IV. and Hadrian IV., the emperors Conrad III. and Frederick I., and also the theologian Guibert of Gembloux, who submitted numerous questions in dogmatic for her determination. It deserves to be specially mentioned to her credit that, though zealously opposed to the Catharists, she stood almost alone in maintaining that the image of God ought to be respected even in them, and that therefore they ought not to be killed. She died in 1179, but has never been canonized; her name, however, was received into the Roman martyrology in the 15th century, September 17th being the day fixed for her commemoration. Her biography, which was written by two contemporaries, Godefridus and Theodoricus, was first printed at Cologne in 1566, and has frequently been reproduced in various forms since that date.

The works of Hildegard, in addition to the *Scivias* already mentioned, include *Divinorum operum simpliciter hominis liber*, a hitherto unpublished treatise containing later visions and revelations, many of them relating to physical and medical questions, *Vita meritorum*, also unpublished, *Lives of St. Rupert and St. Disibod*, *Expositions of the rule of St. Benedict*, and of the Athanasian creed, *Letters*, and *Exhortations*. While her "visions" on such themes of the Christian religion as God and His kingdom, the church and its mystical union to Christ, must be regarded as crude and extravagant even to insanity, it is impossible to deny all ethical or religious value to her earnest denunciations of the corruptions of the clergy and mendicant orders, or to the intense expressions (however ignorant and imperfect) of the life-long aspirations of a mind so singularly unselfish and unworldly as hers. The *Scivias* were printed in 1513 and again in 1628. The *Epistolarum Liber* (first published in 1566) appears with some other *Opuscula* in the *Mar. Bibl. Vet. Patr.*, vol. xxlii., and in Martene and Durand's *Amplissima Collectio*, vol. ii. The *Opera Omnia* form vol. xcviil. of Migne's *Patrologia Cursus Completus*. See Meiners, *De Sancta Hildegardis vita, scriptis meritis* (1793); Dahl, *Die heilige Hildegard* (1832); Görres, *Die Christliche Mystik*.

HILDEN, a town of Prussia, in the government and circle of Düsseldorf, on the Itterbach. It is a station on the Rhenish railway, and has a considerable manufacture of silks, both pure and mixed, calico, and machinery; it also possesses a deaconess institute. During the last half century its growth has been rapid. While in 1816 the population numbered only 2056, it amounted in 1875 to 6789. Hilden was constituted a town in 1861.

HILDESHEIM, the chief town of a district in the province of Hanover, Prussia, is beautifully situated on the right bank of the Innerste, 18 miles south-east of Hanover by railway. It has a very antique and quaint appearance, and is surrounded by old ramparts which have been converted into shady alleys and promenades. The streets are for the most part narrow and irregular, and contain many old houses with overhanging upper stories and richly and curiously adorned wooden façades. The town is the seat of a district governorship, a high court of justice, two justice courts, a general superintendency of the Evangelical Church, and a Roman Catholic chapter. The Catholic cathedral, which occupies the site of a building founded by Louis the Pious in 818, dates from the middle of the 11th century. It is chiefly remarkable for the antiquities and notable works of art connected with it, including the bronze doors executed by Bishop Bernward, with reliefs from the history of Adam and Christ; the so-called Irmensäule, at one time believed to have been

erected, before it was transferred to its present site, in honour of the Saxon idol Irmin, but now regarded as belonging to an old Roman aqueduct; the Christ column by Bishop Bernward, adorned with reliefs from the history of the Saviour; a brazen font of the 13th century, two candelabra of the 12th century, the sarcophagus of St Godehard, the tomb of St Epiphanius, and an immense number of minor articles of ecclesiastical furniture. The rose-bush on the wall of the crypt is alleged to be a thousand years old. Among the other churches those of special interest are St Godehard's church, completed in 1172 and restored in 1863, a remarkably fine specimen of the Romanesque style, with three massive pyramidal towers; the church of St Michael, an almost equally fine specimen of Romanesque, founded by Bishop Bernward, and restored in 1186 after injury by fire, containing a beautiful painted ceiling of the 12th century, and the tomb and monument of Bishop Bernward; St Magdalene's church, which possesses various works in metal by Bishop Bernward; St Martin's church, now used as a museum and library; the Lutheran church of St Andrew, with very lofty towers; and the fine columnar basilica of the abbey church of Moritzburg, a suburb half a mile south-west of the town. The other principal buildings are the town-house, dating from the 15th century, and containing the archives of the town; the house in the late Gothic style said, but erroneously, to have been built by the Knights Templars; the Michaelis monastery, now used as a lunatic asylum; and the old Carthusian monastery. The educational establishments include a Catholic and a Lutheran gymnasium, a Catholic normal school, a weaving school, and an agricultural school. The other principal public institutions are the Georgstift for daughters of state servants, the maternity hospital, two orphanages, and several other hospitals and infirmaries. The town has iron foundries, manufactures of cloth, damasks, linen fabrics, thread, sail-cloth, wadding, leather, machines, carriages, stoves, glass, tobacco, alcohol, perfumeries, chocolate, and starch. The population in 1875 was 22,581.

Hildesheim, though previously in existence, owes its rise and prosperity to the transference to it in 822 of the bishopric instituted by Charlemagne at Elze in 812. In the 10th century its importance was largely increased under Bishop Bernward, who, if he did not introduce, greatly stimulated by his example and patronage the art of working in metals, for which the town retained a high reputation until the close of the Middle Ages. It also obtained considerable fame by its cathedral school, at which several sons of the emperors received their education. In 1241 it joined the Hanseatic League, and in 1249 received town rights. It was frequently at feud with its bishops, and in the 14th century placed itself more than once under the protection of the house of Brunswick-Lüneburg. The bishops in the course of time had acquired considerable territory, but their feuds with the neighbouring princes resulted in 1523 in the annexation of a great part of their possessions to Brunswick. A restoration, however, took place in 1643, and in the beginning of the present century the principality amounted to 682 square miles. The last bishop of Hildesheim possessed also the bishopric of Paderborn, acquired by his predecessor. Both bishoprics were secularized and ceded to Prussia in 1803. In 1807 they were incorporated with the kingdom of Westphalia, but in 1813 they were restored to Prussia, which ceded Hildesheim to Hanover, retaining only Paderborn. In 1866 the principality was united, along with Hanover, to Prussia.

On October 9, 1863, a unique collection of ancient plate was discovered on the Galgenberg near Hildesheim, about 10 feet below the surface. This *Hildesheimer Silberfund*, as it is usually called, has excited great interest among classical archaeologists, comprising, as it does, no less than 60 pieces, or a complete service for three persons—plates, dishes, mixing-bowls, &c. The workmanship evidently belongs to the Augustan age, and by some authorities it is conjectured that we have nothing less than the plate that belonged to Drusus himself. The most noteworthy of the pieces are a crater richly ornamented with arabesques and figures of children, a platter with a representation of Minerva, and others with a boy Hercules, a Cybele, and a Dens Lunus. The whole collection is preserved in the Berlin Museum. For details see Wieseler, *Der Hildesheimer Silberfund*, Bonn, 1868.

HILDRETH, RICHARD (1807-1865), an American journalist and author, was born at Deerfield, Massachusetts, June 28, 1807. He was educated at Harvard College, where he graduated in 1826; and after studying law at Newburyport, he was called to the Boston bar in 1830. He had, however, already conceived a predilection for literature, and in 1832 he became joint founder and editor of a daily newspaper, *The Boston Atlas*. Having in 1834 gone to the south for the benefit of his health, he was led by what he witnessed of the evils of slavery to write the anti-slavery novel *Archy Moore*, which, chiefly on account of its subject, met with considerable success in America and England. An enlarged edition of it appeared in 1852 under the title of the *White Slave*. In 1837 he wrote *Banks, Banking, and Paper Currency*, a work which had some influence in fostering the growth of the free banking system in America. In 1838 he resumed his editorial duties on the *Atlas*, but in 1840 he found it necessary on account of his health to remove to British Guiana, where he was editor of two weekly newspapers in succession at Georgetown. He published in the same year *Despotism in America*, and he also made the columns of his newspapers the medium for the dissemination of anti-slavery opinions. In 1849 he published the first three volumes of a *History of the United States*, a work which, if its narrative is rather bald and tame, is characterized by perfect fairness and candour, and displays great industry and care in the representation of facts. Other three volumes, completing the work, appeared in 1855. His *Japan as it was and is* is a valuable digest of the information contained in other works on that country. He also wrote *Theory of Morals* (1844), and *Theory of Politics* (1853), as well as *Lives of Atrocious Judges*, compiled from Lord Campbell's two works. For some time Hildreth was on the editorial staff of the *New York Tribune*, and he was also a frequent contributor to periodicals. In 1861 he was appointed United States consul at Trieste, but ill health compelled him to resign his office and remove to Florence, where he died July 11, 1865.

HILL, AARON (1685-1749 or 1750), an English poet and miscellaneous writer, was born in London, 10th February 1685. Though left by his father in necessitous circumstances, he was educated first at Barnstaple and then till his fourteenth year at Westminster School, after which he went out to Constantinople, where Lord Paget, a relative of his mother, was British ambassador. Under the care of a tutor he then travelled through Palestine, Egypt, and a great part of the East, returning to England about 1703. Having subsequently quarrelled with his patron, he again went abroad as travelling companion to a Yorkshire baronet. On returning home he published in 1709 his *History of the Ottoman Empire*, which, according to his own admission, had far more success than it deserved. About the same time appeared his poem of *Camillus*, in honour of the famous Charles Mordaunt, earl of Peterborough; and in the same year he was made manager of Drury Lane Theatre, and afterwards of the Haymarket. Both those offices he soon after lost through his indiscretion, and the remainder of his life was spent partly in literary pursuits and partly in commercial speculations, which were all unlucky. One of these schemes called him to the Highlands of Scotland, and while there he wrote *The Progress of Wit, being a Caveat for the use of an eminent Writer*. The "eminent writer" was Pope, who had introduced Hill into the *Dunciad*, though in a way that was in fact complimentary. Hill died in 1749 or 1750, and was buried in Westminster Abbey. Two only of his seventeen dramas are now remembered, *Zara* and *Merope*, both adaptations from the French of Voltaire. His poetry is stilted and commonplace, and even the

Progress of Wit never rises above a flippant smartness. Though a poor and tasteless poet, and afflicted with an overwhelming sense of his own importance, Hill was an honourable man, and his letters to Savage, on whom he conferred many benefits, show his character in a very amiable light. The *Miscellaneous Works* of Hill were published in 1753 in 4 vols. 8vo, and his *Dramatic Works*, to which a *Life* was prefixed, appeared in 1759 in 2 vols. 8vo.

HILL, MATTHEW DAVENPORT (1792-1872), was born August 6, 1792, at Birmingham, where his father, T. W. Hill, was at that time assistant in a charity school. He made such rapid progress in his education that in his thirteenth year he rendered his father efficient assistance in conducting a private school in Birmingham, and in his seventeenth year became the principal teacher. Resolving, however, to adopt the legal profession, he in 1814, while still continuing his scholastic duties, became a student of Lincoln's Inn, and in 1816 began to devote his uninterrupted attention to legal studies. He was called to the bar in 1819, and went upon the Midland circuit, where his ability was soon generally recognized, although for various reasons his acquisition of a profitable practice was not so rapid. In 1832 he was elected one of the Liberal members for Kingston-upon-Hull, but he lost his seat at the next election in 1834. On the incorporation of Birmingham in 1839 he was chosen recorder; and in 1851 he was appointed commissioner in bankruptcy for the Bristol district. Having in the course of his professional duties had his interest excited in questions relating to the treatment of criminal offenders, he in his charges to the grand juries, as well as in special pamphlets, ventilated opinions which have been the means of introducing many important reforms in the methods of dealing with crime. One of his principal coadjutors in these reforms was his brother Frederick Hill, whose *Amount, Causes, and Remedies of Crime*, the result of his experience as inspector of prisons for Scotland, may be said to mark an era in the methods of prison discipline. Hill was one of the chief promoters of the Society for the Diffusion of Useful Knowledge, and the originator of the *Penny Magazine*. He died 7th June 1872.

His principal works are *Practical Suggestions to the Founders of Reformatory Schools*, 1855; *Suggestions for the Repression of Crime*, 1857, consisting of charges addressed to the grand juries of Birmingham; *Mettray*, 1855; *Papers on the Penal Servitude Acts*, 1864; *Journal of a Third Visit to the Convict Gaols, Refuges, and Reformatories of Dublin*, 1865; *Addresses delivered at the Birmingham and Midland Institute*, 1867. See *Memoir of Matthew Davenport Hill*, by his daughters Rosamond and Florence Davenport Hill, 1878.

HILL, ROWLAND (1744-1833), an eccentric and popular English preacher, sixth son of Sir Rowland Hill of Hawkstone, was born there 23d August 1744. After receiving his early education at the grammar school of Shrewsbury and at Eton, he in 1764 entered St John's College, Cambridge. While at the university he made the acquaintance of the Methodist preacher Whitfield, and stimulated by his example he somewhat scandalized the university authorities and his own friends by preaching, before he had obtained holy orders, in the surrounding villages, and conducting religious services in the houses of the sick and poor. After graduating with distinction he took orders, and in 1773 was appointed to the parish of Kingston, Somersotshire, where he began to indulge his favourite taste for open air preaching, and soon attracted great crowds to the services which he held nearly every day of the week. Having on the death of his father in 1780 inherited considerable property, he built for his own use Surrey Chapel, in the Blackfriars Road, London. The chapel was opened on the 8th June 1783. Though now practically occupying the ecclesiastical position of a dissenter, Hill conducted his

services in accordance with the forms of the Church of England, in whose communion he always remained. From the beginning his success was complete, and his chapel soon came to be filled with an audience such as no other preacher in London could boast. During the summer months he made what he called "gospel-tours" into all parts of the country, sometimes extending them to Scotland and Ireland, and attracted wherever he went audiences as numerous and as interested as those which had crowded to hear Whitfield. After these tours he always returned with increased enthusiasm to his duties at Surrey Chapel, where he continued to officiate almost to the day of his death, 11th April 1833. The oratory of Rowland Hill, like that of Whitfield, was specially adapted for rude and uncultivated audiences, and it was equally effective although by more varied means. He possessed a voice of great power, and, according to Southey, "his manner" was "that of a performer as great in his own line as Kean or Kemble." Not unfrequently he violated the laws of good taste in the eccentricities of his wit and humour, but the intensity and purity of the purpose by which he was actuated enabled him always to retain uninjured his moral influence over his audience. Among the various publications of Rowland Hill the best known is his *Village Dialogues*, which first appeared in 1810, and reached a 34th edition in 1839.

See *Life* by Rev. Edwin Sidney, 1833; *Memoirs* by Rev. William Jones, 1834; and *Memorials* by Rev. James Sherman, 1857.

HILL, SIR ROWLAND (1795–1879), author of the penny postal system, a younger brother of Matthew Davenport Hill, and third son of T. W. Hill, who named him after Rowland Hill, the preacher, was born December 3, 1795, at Kidderminster, to which town his father had lately removed from Birmingham. For some years of his childhood his health was very feeble, and as, on account of an affection of the spine, he had to maintain a recumbent position, his principal method of relieving the irksomeness of his situation was by repeating figures aloud consecutively until he had reached very high totals. A similar bent of mind was manifested when he entered school in 1802, his aptitude for arithmetic and mathematics being quite exceptional. But if he owed his subsequent eminence to a peculiar natural talent for figures, he was indebted for the direction of his abilities in no small degree to the guidance of his father, a man of great force of character and of advanced political and social views, which were qualified and balanced by the strong practical tendency of his mind. At the age of twelve Rowland began to assist in teaching arithmetic and mathematics in his father's school at Hilltop, Birmingham, and latterly he had the chief management of the school. On his suggestion the establishment was removed in 1819 to Hazelwood, a more commodious building in the Hagley Road, in order to have the advantages of a large body of boys, for the purpose of properly carrying out an improved system of education. That system, which was devised principally by Rowland, was expounded in a pamphlet entitled *Plans for the Government and Education of Boys in large numbers*, the first edition of which appeared in 1822, and a second with additions in 1827. The principal feature of the system was "to leave as much as possible all power in the hands of the boys themselves;" and it was so successful that, in a circular issued six years after the experiment had been in operation, it was announced that "the head master had never once exercised his right of veto on their proceedings." This doubtless was in no small degree due to the powerful personality of Rowland Hill, which made itself felt whether he was present or not. The system, it must be admitted, had several features of too utopian a character for the present constitution of society; but on the whole Rowland Hill, as an educationist, is entitled to a place side by side with Arnold of

Rugby, and was equally successful with him in making moral influence of the highest kind the predominant power in school discipline. After his marriage in 1827 Hill removed to a new school at Bruce Castle, Tottenham, which he conducted until failing health compelled him to retire in 1833. About this time he became secretary of Gibbon Wakefield's scheme for colonizing South Australia, the objects of which he explained in 1832 in a pamphlet on *Home Colonies*, afterwards partly reprinted during the Irish famine under the title *Home Colonies for Ireland*. It was in 1835 that his zeal as an administrative reformer was first directed to the postal system. The discovery which resulted from these investigations is when stated so easy of comprehension that there is great danger of its originality and thoroughness, and its greatness as an element in human progress, being lost sight of. A fact which also enhances its merit was that he was not a post-office official, and possessed no practical experience of the details of the old system. After a laborious collection of statistics he succeeded in satisfying himself and in demonstrating to the world that the principal expense of letter carriage was in receiving and distributing, and that the cost of conveyance differed so little with the distance that a uniform rate of postage was in reality the fairest to all parties that could be adopted. Trusting also that the deficiency in the postal rate would be made up by the immense increase of correspondence, and by the saving which would be obtained from prepayment, from improved methods of keeping accounts, and from lessening the expense of distribution, he in his famous pamphlet published in 1837 recommended that within the United Kingdom the rate for letters not exceeding half an ounce in weight should be only one penny. The employment of postage stamps is mentioned only as a suggestion, and in the following words:—"Perhaps the difficulties might be obviated by using a bit of paper just large enough to be the stamp, and covered at the back with a glutinous wash which by applying a little moisture might be attached to the back of the letter." Proposals so striking and novel in regard to a subject in which every one had a special personal interest could not fail to command general attention, and perhaps no pamphlet that ever issued from the press has caused so much and such widespread discussion, or been so speedily effective in promoting reforms in any degree so beneficial to the human race. So great became the pressure of public opinion against the opposition offered to the measure by official prepossessions and prejudices that in 1838 the House of Commons appointed a committee to examine the subject. The committee having reported favourably, a bill to carry out Hill's recommendations was brought in by the Government. The Act received the royal assent in 1839, and after an intermediate rate of fourpence had been in operation from December 5th of that year, the penny rate commenced January 10, 1840. Hill received an appointment in the Treasury in order to superintend the introduction of his reforms, but he was compelled to retire when the Liberal Government resigned office in 1841. In consideration of the loss he thus sustained, and to mark the public appreciation of his services, he was in 1846 presented with the sum of £13,360. On the Liberals returning to office in the same year he was appointed secretary to the postmaster-general, and in 1854 he was made chief secretary. In these positions, his ability as a practical administrator made itself felt in every department of the postal system, and enabled him to supplement his original discovery by practical expedients realizing its benefits in a degree commensurate with continually improving facilities of communication, and in a manner best combining cheapness with efficiency. In 1860 his services were rewarded with the honour of knighthood;

and when failing health compelled him to resign his office in 1864, he received from parliament a grant of £20,000, and was also allowed to retain his full salary of £2000 a year as retiring pension. In 1864 the university of Oxford conferred on him the degree of D.C.L., and on the 6th June 1879 he was presented with the freedom of the city of London. The presentation, on account of his infirm health, took place at his residence at Hampstead, and he survived the ceremony only a few weeks, dying on the 27th August following. He was buried in Westminster Abbey.

HILL, VISCOUNT (1772-1842). Rowland Hill, nephew of the Rev. Rowland Hill, was born at Prees, Shropshire, 11th August 1772. After receiving his early education at Ighfield and Chester, he was gazetted to the 38th regiment, obtaining permission at the same time to improve himself in the knowledge of his profession in a military academy at Strasburg, where he continued after removing into the 53d regiment with the rank of lieutenant. In the beginning of 1793 he raised an independent company, and was promoted to the rank of captain. The same year he distinguished himself at the siege of Toulon; and after serving for some time on the Continent he in 1797 set out as colonel of the 90th regiment with Sir Ralph Abercromby's expedition to Egypt, where he acquired great distinction, and was wounded at the battle of Alexandria. Having in 1803 been gazetted brigadier-general, he in 1808 accompanied Sir Arthur Wellesley to Spain, and from Vimiera to Vittoria, in advance or retreat, he proved himself the most indefatigable coadjutor of the great captain. In 1809 he was gazetted lieutenant-general, and in the following year was appointed to the independent command of the second army corps of Wellington in Portugal; in 1811 he annihilated the French army under Girard at Arroyomolinos (Caceres), in recognition of which he received the order of the Bath; and for his capture of the forts of Almaraz, which cut off the communication between the French armies on the north and south sides of the Tagus, he was in 1814 rewarded with the title of Baron Hill of Almaraz. In 1813 he held temporarily the command of the English and Hanoverian troops in Belgium, and two years later crowned the glories of his noble career by his conduct at Waterloo, where he was at the head of the brigade which resisted and repulsed the last effort made in behalf of the French by the imperial guard. When Wellington became premier in 1828 Hill received the appointment of general commanding-in-chief, and on resigning this office in 1842 he was created a viscount. He died on the 10th December of the same year. Lord Hill was, next to Wellington, the most popular and able soldier of his time in the British service, and was so much beloved by the troops, especially those under his immediate command, that he gained from them the honourable title of "the soldier's friend." "With Hill," they used to say, "both victory and life may be ours." On the other hand, the strategic skill and military capacity he displayed in the Peninsula secured for him the not less honourable title of "the right arm of the duke of Wellington." From the first day he entered the army he displayed the germs of those qualities that afterwards secured for him fame, rank, and power—boldness that amounted to daring and was yet always under the control of calm judgment, skill equal to independent commands of the most difficult kind, and a regard for the moral and physical welfare of the army such as had never before been shown by any commander-in-chief.

The *Life of Lord Hill, G.C.B.*, by Rev. Edwin Sidney, A.M., appeared in 1845.

HILLAH, a town of Asiatic Turkey in the pashalik of Bagdad, from which town it lies 60 miles to the south. It is picturesquely situated, in the midst of a very fertile

district, on both banks of the Euphrates, which are connected there by a floating bridge 450 feet in length. The estimated population, which includes a large number of Jews, varies from 6000 to much above 10,000. The bazaars are large and well supplied; and tanning, dyeing, and silk manufacture are carried on to a considerable extent. The horse mart has recently declined in repute. Hillah occupies the site of the ancient Babylon, and is to a large extent built of bricks obtained from the ruins.

HILLARD, GEORGE STILLMAN (1808-1879), an American author, was born at Machias, State of Maine, September 22, 1808. After graduating at Harvard College in 1828, he became joint rector of the Round Hill Seminary at Northampton. In 1833 he was called to the Boston bar, where he soon obtained a good practice. He was chosen a member of the common council of Boston in 1845, and he was for six months its president. In 1849 he was elected a member of the State legislature. The engrossing character of his professional and other engagements did not, however, prevent him from devoting a large portion of his time to literature. Besides editing successively the *Christian Register* (a Unitarian paper), *The Jurist*, and the *Boston Courier*, he published an edition of Spenser's works (in 5 vols., 1839), and a selection from the works of Walter Savage Landor (1856), and wrote *Six Months in Italy* (2 vols., 1833), *Life and Campaigns of George B. McClellan* (1865), a series of school-books which have met with wide acceptance, and various articles in periodicals and encyclopædias. In addition to this he made frequent successful appearances as a public lecturer. From 1867 to 1878 he was United States district attorney for Massachusetts. He died 27th January 1879.

HILLEL, a famous Jewish rabbi, sometimes called for distinction's sake רִבִּי, "the elder" or "the old," flourished about the time of Herod the Great. According to the Talmudists he was born of a poor Davidic family, at Babylon, apparently about the year 75 B.C. In his zeal for the study of the law he went, when already of mature age, to Jerusalem, where Shemaiah and Abtalion were at that time the leading teachers. While supporting himself and his family there by working as a day labourer, he was not always able to earn the fee which the porter of the Beth-Midrash or house of instruction is said to have required; but such was his ardour for learning that on one occasion on a cold December morning, having failed to obtain admission, he climbed up to the window of the class-room, where some time afterwards he was found quite buried and half frozen to death under a heavy fall of snow. He was now made free of the schools, and so great were the attainments with which his diligence was ultimately rewarded that, according to the tradition, he understood all languages, including those of the hills and the valleys, the trees and the flowers, the beasts and the demons. In his later years he succeeded the "sons of Bethyras" in the presidency of the sanhedrin, and in this high position he became the author of several important rules of interpretation (the so-called seven "middoth"; see HERMENEUTICS), and also of some authoritative legal decisions. A contemporary, and perhaps a pupil of his, was Shammai, who became the head of a rival and at times bitterly hostile school. Dying about the year 10 A.D., Hillel was succeeded in his official position by his son Simcon, and afterwards by his grandson Gamaliel I.

There is evidently a good deal of what is incredible in the above Talmudic account; for example, it is now recognized on all hands that the Talmudic statement as to Hillel's presidency over the sanhedrin is absolutely irreconcilable with what we learn from the New Testament writers and from Josephus, and must be regarded as wholly unhistorical. But after every reasonable deduction has been duly made, we still have ample traces of a strong personality, characterized by unusual sweetness and light, bent on support-

the claims of a right-minded and ethical religion against those of mere sacerdotal traditionalism. His "middoth," so far as they go (but they do not go far), are based on sound principles of logic and hermeneutic; the so-called "proshol," by which he evaded the restrictions laid upon commerce through the law relating to the sabbatic year, showed that he possessed at least some power of adapting old institutions to the changing circumstances and wants of a progressive society; and if most of the questions which are alleged to have divided his school from that of Shammai cannot but strike the modern reader as having been infinitely small, the "golden rule" and some other sayings attributed to him show that he was not incapable of large and true views on the deepest problems of human life.

A remote descendant of the same name, who flourished about 350 A.D., is said to have sought to quiet his co-religionists, restive under foreign domination, with the novel doctrine that all the "Messianic" prophecies of the Old Testament had related to Hezekiah, and had been fulfilled in him.

Our only source of information with regard to Hillel "the old" is the Talmud, unless indeed the Pöllion referred to once and again by Josephus be also Hillel under a Greek name. For the grounds on which this probable identification rests, and for a masterly sketch of Hillel and his place in the history of Israel, the great work of Ewald may be consulted (*Gesch. d. V. Israel*, vol. v.). See also Delitzsch, *Jesus u. Hillel* (3d ed., 1879); Derenbourg, *Histoire de la Palestine*, pp. 178-92; and Schürer, *Neutestamentliche Zeitsgeschichte*, sec. 25. All the recent works dealing with the life of Christ also touch upon this subject, especially with reference to the question regarding the "originality" of the two teachers. Reuan, Keim, and Farrar (vol. ii. appendix) may be specially named.

HILLER, JOHANN ADAM (1728-1804), musical composer, was born at Wendisch-Ossig near Görlitz in Silesia, December 25, 1728. By the death of his father in 1734 he was left dependent to a large extent on the charity of friends. Entering in 1747 the Kreuzschule in Dresden, the school frequented many years afterwards by Richard Wagner, he afterwards went to the university of Leipsic, where he studied jurisprudence, supporting himself by giving music lessons, and also by performing at concerts both on the flute and as a vocalist. Gradually he adopted music as his sole profession, and devoted himself more especially to the permanent establishment of a concert institute at Leipsic. It was indeed he who originated (in 1781) the celebrated Gewandhaus concerts which still flourish at Leipsic. In 1789 he became "cantor" of the Thomas school there, a position previously held by the great John Sebastian Bach. He died June 16, 1804. Two of his pupils placed a monument to his memory in front of the Thomas school. Hiller's compositions are numerous, and comprise almost every kind of church music, from the cantata to the simple chorale. But infinitely more important are his operettas, 14 in number, which for a long time retained their place on the boards, and had considerable influence on the development of light dramatic music in Germany. The *Jolly Cobbler*, *Love in the Country*, and the *Village Barber* were amongst the most popular of his works. Hiller also excelled in songs and ballads of the sentimental kind. With great simplicity of structure his music combines a considerable amount of genuine melodic invention. Although an admirer and imitator of the Italian school, Hiller fully appreciated the greatness of Handel, for the appreciation of whose music in Germany he did much. It was under his direction that the *Messiah* was for the first time given at Berlin, more than forty years after the composition of that great work. Hiller was also a writer on music, and for some years (1766-1770) edited a musical weekly periodical named *Wöchentliche Nachrichten und Anmerkungen die Musik betreffend*.

HILL TIPPERAH, a native state adjoining the British district of Tipperah, Bengal, lying between 22° 59' and 24° 31' N. lat., and between 91° 12' and 92° 24' E. long., with an area of about 3867 square miles, and population (1878) 75,792. It is bounded on the N. by the Assam district of Sylhet, on the W. by the Bengal districts of Tipperah and Noákhálí, on the S. by Noákhálí and Chittagong districts, and on the E. by the Lusháí country and the Chittagong Hill Tracts. As its name implies the country is hilly. Five or six ranges of hills run parallel from north to south, at an average distance of about 12 miles from each other.

The hills are covered for the most part with bamboo jungle, while the low ground abounds with trees of various kinds, canebrakes, and swamps. The principal ranges are, beginning from the east, the Jámpui, Sakkankhang, Langtaráí, and Atháramurá. The chief rivers are the Gumti, Háorá, Khozái, Duláí, Manu, and Phení. During the heavy rains the people in the plains use boats as almost the sole means of conveyance. The forests give shelter to numbers of wild elephants and other large game. Small game of various kinds are met with.

The history of the state relates to two distinct periods—the traditional period described in the *Rájmáld*, or "Chronicles of the Kings of Tipperah," and the period since 1407 A.D. The *Rájmáld* is a history in Bengálí verse, compiled by the Bráhmans of the court of Tripurá. In the early history of the state, the rájás were in a state of chronic feud with all the neighbouring countries. The worship of the All-destroyer was here, as elsewhere in India, associated with the practice of human sacrifice, and in no part of India were more victims offered up. It was not until the beginning of the 17th century that the Mughals obtained any footing in this country. By dint of constant invasions and continual intrigues, the Mahometans gradually established themselves, and Tipperah soon became a mere Mughal province under a Mussulman governor. The rájá still remained in possession of the hilly tracts, but subject to the nawáb of Murshidabad. When the East India Company obtained the *duwán* of Bengal in 1765, so much of Tipperah as had been placed on the rent-roll came under British rule. Since 1808, each successive ruler has received investiture from the British Government, and has been required to pay the usual *nazar* or tribute on accession. The state has a chronological era of its own, adopted by Rájá Bir-ráj, from whom the present rájá is 92d in descent. The year 1875 corresponded with 1285 of the Tipperah era.

Both as regards its constitution and its relations to the British Government, the state of Hill Tipperah differs alike from the independent native states of India and from those which are tributary and dependent. Besides being the ruler of Hill Tipperah, the rájá holds an estate in the British district of Tipperah, called *chaklá* Roshnábad, which is by far the most valuable of his possessions. The form of government is despotic and patriarchal. The rájá's word is law, without appeal. In 1871 an English officer was appointed as political agent to protect British interests and advise with the rájá. The most important hill tribe is that of the Tipperahs, who were estimated in 1874-75 to number 34,727. There are no towns in Hill Tipperah. Agatalá, the capital of the state and residence of the rájá, is merely a moderate-sized village situated on the north bank of the Háurá.

The principal crop and main food staple is rice. The other articles of produce are cotton, chillies, and vegetables. The chief exports are cotton, timber, *tíl*, bamboo canes, thatching-grass, and firewood. Occasionally small imports are required from the neighbouring districts. The total revenue in 1874-75 was £18,693. Besides this, the rájá's estates in Tipperah and Sylhet yield about £50,000 and £1400 respectively. His total annual income, therefore, is about £70,000. The police force (1874-75) consisted of 102 men, and the rájá maintains a force of 277 officers and men. The state has only 2 schools, and only 103 boys are being educated. The climate of Hill Tipperah is generally pleasant; the annual rainfall is 60 inches. The chief endemic diseases are bowel complaints, remittent and intermittent fevers, and rheumatism; the principal epidemic is cholera.

HILTON, WILLIAM (1786-1839), English painter, was born in Lincoln on 3d June 1786, son of a portrait-painter, who was probably his first instructor. In 1800 he was placed with the engraver J. R. Smith, and about the same time began studying in the Royal Academy School. He first exhibited in this institution in 1803, sending a group of Banditti; and, though he could not be called a popular artist, he soon established a reputation for choice of subject, and qualities of design and colour superior to the great mass of his contemporaries. He made a tour in Italy along with Thomas Phillips, the portrait-painter. In 1814, having exhibited Miranda and Ferdinand with the Logs of Wood, he was elected an associate of the Academy, and in 1820 a full academician, his diploma-picture representing Ganymede. In 1823 he produced Christ crowned with Thorns, a large and important work, which has lately been bought by the Academy out of the Chantrey Fund; this may be regarded as his masterpiece, displaying all the qualities which go to make up pictorial propriety and efficiency, though it does not entitle Hilton to the praise of

original genius. In 1825 he succeeded Fuseli as keeper of the Academy; and he died in London on 30th December 1839, a widower without children. Some of his best pictures remained on his hands at his decease,—such as the Angel releasing Peter from Prison (life-size), painted in 1831, Una with the Lion entering Corceca's Cave (1832), the Murder of the Innocents, his last exhibited work (1838), Comus, and Amphitrite. The National Gallery now contains Edith finding the Body of Harold (1834), Cupid Disarmed, Rebecca and Abraham's Servant (1829), and Sir Calepino rescuing Serena (from the *Faerie Queen*) (1831). Hilton's excellence as an artist is relative to the state of art in his country at the time. In a great school or period he could certainly not count as more than a respectable subordinate; but in the British school of the earlier part of this century he had sufficient elevation of aim and width of attainment to stand conspicuous and praiseworthy, and, comparatively speaking, above the level of mediocrity.

HILVERSUM, a village and commune in the Netherlands in the province of North Holland, about equally distant from Amsterdam, Utrecht, and Amersfoort, with all of which it is connected by railway. The village is well sheltered on the west and north-west by a range of hills, and since 1874 it has been the seat of a hospital, the Trompenberg, for convalescents. The public buildings comprise a town-house and four churches and a synagogue, and there is a very handsome railway station. The weaving of floor-cloths, horse blankets, and Hilversum stripe is the principal industry. In 1423 Hilversum was separated from Laren. In 1505 it suffered at the hands of the people of Guelderland, in 1629 from the Croats, and in 1672 from the French. The population of the village in 1840 was 5160, and in 1870 5611; while that of the commune in the same years was 5314 and 6615. Of this last number 3463 were Roman Catholics, 2327 belonged to the Dutch Reformed Church, and 226 were Jews.

H I M A L A Y A

HIMALAYA is the name given to the mountains which form the northern boundary of British India, between the 75th and 95th meridians east of Greenwich. The word is Sanskrit, and literally signifies "snow-abode," from *him*, snow, and *ālayā*, abode, and is well translated "snowy-range," though that expression is perhaps more nearly the equivalent of *Himāchāl*, another Sanskrit word, derived from *him*, snow, and *āchāl*, mountain, which is practically synonymous with Himalaya, and probably as often used in conversation by natives of northern India. The letter *y* in the last syllable of Himsalaya is purely a consonant, and the last two syllables should be pronounced *lā-yā*, the conversion of the *ay* into a diphthong being quite erroneous. The name, by transformations such as are common to all times and nations in the use of foreign words, was converted by the ancient Greeks into *Emodos* and *Imuos*.

Although the term Himalaya is applied by the natives of India only to the ranges which they see covered with perpetual snow, it has been long used by European geographers to designate the whole mountain region for which the Indian has no other name than *pāhār*, *i.e.*, "the mountains," of which the snowy ranges constitute but a small portion. The first mere cursory examination of these mountains by the older geographers rightly convinced them of the general physical unity of the mountainous region to the north of India, which in length extends from about 72° to 95° E. long., that is, between the rivers Indus and Brahmaputra, and in breadth includes the ranges between the plains of Hindustan and the upper parts of the main branches of these two great rivers. To these ranges the designation of Himalaya has by degrees been specially attached; and there is a certain convenience in still restricting the name to that part of the mountains which is accessible from British India, for this is the practical signification of it now commonly accepted.

Though it is to the area thus limited that the present article is mainly designed to refer, it will be necessary, for the correct apprehension of some of its main characteristics, to understand aright the relation which the Himalaya bears to the great mountain region beyond it, and a general description of that region thus becomes requisite.

Scientific investigation has clearly shown that, so far as the main characteristics of the mountains are concerned, the natural boundaries of the Himalayan system must be carried much farther than had at first been recognized. Considerable obscurity still involves the eastern portion of these mountains, and there is great want of precise knowledge as to their connexion with the ranges of western China,

from which are thrown off the great rivers of China, Siam, and Burmah. On the west, however, it has been completely established that a continuous chain extends beyond the Indus along the north of the Oxus, and ends in that quarter about 68° E. long. In like manner it is found that no separation can be established, except a purely arbitrary one, between the Himalaya as commonly defined and the greatly elevated and rugged table-land of Tibet; nor between this last and the mountain ranges which form its northern border along the low-lying desert regions of Central Asia.

It thus appears that the Himalaya, with its prolongation west of the Indus, constitutes in reality the broad mountainous slope which descends from the southern border of the great Tibetan table-land to the lower levels of Hindustan and the plains of the Caspian; and that a somewhat similar mountain face, descending from the northern edge of the table-land, leads to another great plain on the north, extending far to the eastward, to the northern borders of China. Towards its north-west extremity this great system is connected with other mountains,—on the south, with those of Afghanistan, of which the Hindu-Kush is the crest, occupying a breadth of about 250 miles between Peshawur and Kündüz; and on the north, with the mountains that flank the Jaxartes or Sir on the north, and the Thian-shan or Celestial Mountains. The eastern margin of Tibet descends to western China, and the south-eastern termination of the Himalaya is fused into the ranges which run north and south between the 95th and 100th meridians, and separate the rivers of Burmah, Siam, and western China.

Nor can any of the numerous mountain ranges which constitute this great elevated region be properly regarded as having special, definite, or separate existence apart from the general mass of which they are the component parts; and Tibet cannot be rightly described, as it has been, as lying in the interval between the two so-called chains of the Himalaya and the Kouenlun or Kara Koram. It is in truth the summit of a great protuberance above the general level of the earth's surface, of which these alleged chains are nothing more than the south and north borders, while the other ranges which traverse it are but corrugations of the mass more or less strongly marked and locally developed.

The average level of the Tibetan table-land may be taken at about 15,000 feet above the sea. The loftiest points known on the earth's surface are to be found along its southern or Himalayan boundary; one of them falls very little short of 30,000 feet in elevation, and peaks of 20,000

feet abound along the entire chain. The plains of India which skirt the Himalayan face of the table-land, for a length of rather more than 1500 miles, along the northern border of British India, nowhere rise so much as 1000 feet above the sea, the average being much less. The low lands on the north, about Kashgar and Yarkend, have an elevation of from 3000 to 4000 feet, and no part of the Central Asiatic desert seems to fall below 2000 feet, the lake of Lob-nor being somewhat above that level. The greatest dimension of the Tibetan mountain area from east to west may be about 2000 miles, while its average breadth somewhat exceeds 500 miles; about 100 miles on either side constitute the sloping faces, the central table-land having a width of about 200 miles on the west and probably 500 miles at its eastern border.

The southern portion of the Tibetan table-land throws off its waters to the north-west and south-east from a central line almost on 82° E. long., the Indus flowing in the former direction, and the Brahmaputra in the latter. These two rivers maintain their courses for a great distance in opposite ways, longitudinally, along the summit of the table-land; they receive as they proceed the drainage of a large portion of its surface; and their accumulated waters are at length discharged by two openings in the Himalayan slope across the plains of Hindustan into the Indian Ocean. With the one exception of the basin of the Sutlej, the Tibetan area that discharges itself southward at points intermediate between the debouchure of the Indus and that of the Brahmaputra is comparatively insignificant. No important part of the drainage of the table-land, so far as is yet known, passes in the opposite direction through the northern slope to join the rivers which flow from that slope to the Central-Asiatic plain. The waters of the southern slope, together with the drainage of the exceptional Tibetan area above referred to, traverse the Himalaya more or less directly, and constitute the main tributaries of the Indus, the Ganges, and the Brahmaputra.

Thus the northern border of the table-land, or the summit of its northern slope, so far as it is known, seems to form the real watershed between the rivers that flow to the Indian Ocean and those that lose themselves in the plains of Turkistan and Mongolia. The summit of the Himalayan slope forms a subordinate watershed, separating the rivers that fall into the Indian Ocean into two classes, those that pass directly through the Himalaya to the plains of India, and those that are collected on the summit of the table-land and discharged, also through the Himalaya, but by two concentrated streams at distant points towards the opposite ends of the chain. It has been proposed to call these dividing lines, respectively, the Turkish and the Indian watershed.

The waters that issue from the Himalaya to the west of the 77th meridian combine to form the Indus. Between the 77th and 88th meridians all the streams fall into the Ganges, and eastward of the 88th meridian into the Brahmaputra. Of the continuity of the Brahmaputra, beyond the point up to which it has been explored from Assam, with the Tibetan river called on the maps Sanpoo, Yarou-dzangbo-tchou, and so forth, there is no room for doubt. The correct Tibetan name for the river is Tachok-tsangpo, *i.e.*, "Horse-river," or simply "Tsangpo," *i.e.*, "Great river,"—the word "tsangpo" being applied exactly like the corresponding Indian term "ganga," or the Chinese "kyang," as a generic affix to the name of any large river. In the mountains on the border of Assam the river is called "Dihong," but on entering the plain it receives the waters of the sacred stream locally called "Lohit," which is also believed to have a Tibetan source; and this name the united river retains throughout the greater part of its

course in Assam, Brahmaputra being a classical Sanskrit name not commonly used. In its course through Bengal local names are given to the various branches into which it there divides; and this is also the case with the Ganges, which unites with the Brahmaputra about 100 miles from the sea. That part of Tibet which lies north of the 30th parallel of latitude and between the 82d and 92d meridians east is believed to have no escape open for its waters, which are consequently collected in lakes occupying depressions on its surface. The region east of the 92d meridian, excluding the comparatively small tract which drains into the Brahmaputra, feeds the great rivers of western China, Siam, and Burmah.

At the western extremity of the Tibetan table-land two transverse watershed lines are established in connexion with it, by mountain ranges nearly at right angles to what may be regarded as its general direction in this region,—first, on the south by the mountains which under the name of Hindu-Kush form the north-east angle of the high land of Afghanistan, and from the north-west of which the waters flow into the Oxus (the true Turki name of which is "Amu"), and thence to the Aral Sea, while those from its south-eastern face join the Indus through the Cabul river; and second, on the north by the Terek-tagh, which unites the Tibetan system with the mountains of northern Turkistan, and separates the Jaxartes (in Turki "Sir") from the basin of Yarkend. The Oxus and Jaxartes flow off to the Aral Sea in a north-westerly direction, having between them a range which probably represents the extremity of either the Tibetan or the Thian-shan mountains, and which falls away into hills of minor importance beyond the 70th meridian.

Some further particulars of the relations of the Tibeto-Himalayan region with the contiguous mountain systems, and of its influence both physical and political on the Asiatic continent in the heart of which it is situated, are contained in the article ASIA, to which reference may be made. A more detailed account of TIBET will be given under that heading, and the remainder of this notice will be confined to the description of the restricted Himalayan area, as already defined.

The northern provinces of British India occupy the great plain which flanks the Himalaya on the south, along its whole extent from the issue of the Brahmaputra on the east to the ranges that lie along the Indus. The whole tract, excepting Assam, *i.e.*, the valley of the Brahmaputra, is highly cultivated and populous; and with the same exception the population throughout is of the race known as Aryan, being almost exclusively Hindu in religion on the east, but passing into Mahometan on the west.

The most eastern portion of the Himalayan mountain slope, as far as the 92d meridian, is occupied by wild tribes of which, or of the country they occupy, little is known. They are in small communities under petty chiefs, and their languages, which vary considerably in detail, are to some extent allied to Tibetan and monosyllabic. Between the 92d and 89th meridians is the small state of Bhotán, the local name of which is "Lhopato." It approximates in language, customs, and religion to Tibet proper, and its government is carried on by two separate chiefs, temporal and spiritual. Its northern border, where it is met by Tibet, lies along the 28th degree of north latitude. The small British district of Sikim, succeeds, occupying the lower part of the basin of the Tista river, and having Darjeling as its chief settlement. The native state of Sikim, in Tibetan called "Demojong," extends north of British Sikim to Tibet; it is almost as Tibetan as Bhotán, and still less important. Its western border falls nearly on the 88th meridian.

From the 88th nearly to the 80th meridian the whole southern slope is occupied by the kingdom of Nepal, which

since the wars with the British in 1814-16 has retained complete independence. The jealousy with which its government has excluded Europeans from most parts of the country leaves us with little precise knowledge of any part of it except its eastern border and the neighbourhood of the capital, Káthmándú. The people pass from the Tibetan and Buddhist type, which prevails on the east, into almost pure Hindus, speaking a Hindi dialect, on the west. The rivers Kosi, Gandak, Rápti, and Karnáli are the principal streams that issue from this part of the mountains. The northern border of Nepál follows the main watershed, and its western angle reaches the 30th parallel of north latitude in the vicinity of the well-known Tibetan lakes Rákas-tál and Mánasarowar, where the general direction of the mountains has, from east and west, become nearly south-east and north-west.

The Káli or Sárda river forms the boundary between Nepál and the British provinces of Kumaon and Garhwál, the chief town in which is Almora, and which occupy the entire mountain face, from the watershed to the plains, as far as the main stream of the Ganges, for a distance from east to west of about 100 miles. Thence, an equal distance brings us to the Sutlej, the intermediate tract being occupied by many small principalities, independent in their civil government, but entirely under the political control of the British. In this region is situated Simla, the summer capital of the government of British India, on one of the outer ranges overlooking the Sutlej. Other small districts and principalities, partly British, occupy the Himalayan slope as far as the 76th meridian, beyond which we reach the territories of Jamu and Kashmir, which extend to within 50 miles of the Indus, a narrow band bordering on which river is mainly in the possession of Afghan tribes but partly under British rule. From the portion of the mountains west of the 79th meridian issue the rivers Ganges and Jumna; also the five rivers of the Punjab,—the Sutlej, the Rávi, the Chenáb, the Jhelum, and the Indus, besides the Byás which unites with the Sutlej. The valley of Kashmir is the upper part of the basin of the Jhelum.

The population of the whole of the mountain districts west of Nepál maintains to a great extent its Hindu type, though the Mahometan religion gradually becomes more prevalent as we approach the Indus, where it is found to have superseded Hinduism. In the more remote and elevated valleys an infusion of Tibetan race, religion, and language is found, diminishing as we pass to the west; but otherwise the dialects spoken are everywhere Prakritic, and closely allied to Hindi. As a rule the people are short in stature, muscular, as is common among mountaineers, fairer than the inhabitants of the plains, and in the western regions, where the Hindu or Aryan stock prevails, women of remarkable beauty are often seen. At the lower altitudes cotton clothing is usual, at the greater elevations hempen and woollen materials prevail, but an utter disregard of personal cleanliness is universal. Goitre is frequent in both sexes, and cretinism seems to occur much in the European form.

The eastern ranges are wetter, the climate generally warmer and more equable, and the vegetation more rank and of a more tropical character; the mountains are more copiously covered with forest, and the extent of cultivation is less, and the population probably less also. To the west, with a drier atmosphere and greater variations of temperature, the climate above 5000 or 6000 feet becomes more like that of southern Europe, and the main features of the scenery become more conspicuously similar to those of European mountains. On the east the customs of the people differ little from those of the neighbouring Tibetan or semi-Tibetan provinces. On the west there is no great distinction between the people of the hills and of the plains in their customs, agriculture, or other occupations.

The summit of the table-land from the borders of China Tibet to the 75th meridian, where the Indus suddenly turns off to the south, is comprised in Tibet, or as it is called in the language of its inhabitants "Bod" or "Bodyul," the latter word being equivalent to "Bod-land." Of the eastern half of Tibet very little is known, and that little chiefly relates to the most southern portion which borders on the Himalaya, and the most eastern which abuts on China. The table-land here has its greatest development, and is perhaps as much as 500 miles from north to south. At its north-western end its breadth is reduced to something under 200 miles. The physical features of Tibet, from its great elevation, are so peculiar, and it is so cut off by nature from communication with its neighbours, that it is not surprising to find in it a distinct race with a language of their own, and habits widely different from the surrounding nations. The extreme cold and drought make Tibet essentially poor; and the character of its inhabitants approaches that of the denizens of the Arctic regions, who live under somewhat similar physical conditions. The people are broadly built, with a strongly marked Mongolian physiognomy, dark hair, little or no beard, oblique eyes, and prominent cheek bones. In the warmer valleys they are mainly agricultural, and live in houses; in the higher regions they are shepherds, living in tents, thinly scattered over a large area. They are clothed in woollens or sheep skins. The practice of polyandry prevails, a woman marrying a whole family of brothers. The government at Lhassa is nominally administered by the Tibetans themselves, but in reality is altogether under the control of a Chinese resident. The authority of the Lhassan Government extends to about 78° E. long.; west of this as far as the Indus, the country was conquered some forty years ago by the sovereign of Kashmir and remains under him. In the most western province of Tibet, called "Balti," the Buddhist religion ceases to prevail; the population is exclusively Mahometan, and that religion only is known beyond the Indus.

To the west of Tibet the mountains are prolonged to the 70th meridian at an elevation not greatly less than that which prevails eastward, and the table-land there ends in the region known as Pamir, which has all the characteristics of the higher parts of Tibet. Beyond this we pass into Turkistan and reach the limits by which the scope of the present article is restricted.

The difficulty of accomplishing with any approach to success such a task as that of giving a sufficient account of the chief physical and other characteristics of mountains like the Himalaya is much diminished by the remarkable uniformity in many points of structure and other important peculiarities, which prevails along the whole length of the chain. The perception of such general characteristics among mountains so vast is, indeed, too often overshadowed and obscured by the magnitude of their parts, the multitude of their details, and the variety of their forms; yet when the idea of the subordination of all these elements to common laws has once been duly conceived, it obtains constantly growing confirmation from what at first only produced impressions of hopeless confusion.

The great plain of northern India stretches with an almost unbroken surface along the foot of the Himalaya from the upper Indus to the head of the delta of the Ganges, and thence has a narrow prolongation along the Brahmaputra up the valley of Assam. Including its extensions to the sea, along the Indus on the west, and along the Ganges on the east, its area is about 500,000 square miles. It nowhere rises to more than 1000 feet above the sea-level, and to the unassisted eye it appears a perfectly dead flat. That part of the plain which lies along the foot of the mountains, and more particularly the central and eastern portion, is well watered, being intersected by the numerous streams

that flow from the mountains, and under the full influence of the periodical rains, and it comprises the best cultivated, the richest, the most populous, and most civilized districts of India.

The snowy peaks of the Himalaya are, under favourable conditions, visible from the plains at a distance of about 200 miles. It is not, however, till the traveller is within 30 or 40 miles of the foot of the mountains that the outlines of the great peaks become well defined and their grandeur appreciable. At about the same distance, too, the lower ranges begin for the first time to attract attention. At about 20 or 25 miles from the outer hills the cultivation of the plain commonly becomes less complete, and the villages more sparse; an open grassy tract is entered, often traversed by shallow, sluggish streams, along which are formed morasses, or fringes of gigantic reeds and grasses, frequently occupying very large areas. This tract is known as the "Tarai," or "Tariyáni." Where most strongly developed it has a width of 10 or 15 miles, but its existence is manifestly greatly dependent on the local conditions of drainage and of rainfall, and to the west of the point where the Ganges leaves the mountains the Tarai is not formed. It has been erroneously described as a depression along the foot of the mountains, but there is no foundation for such a view, and the causes that lead to the formation are not far to seek.

To explain these it is necessary to take a further step towards the mountains. Just as the Tarai somewhat suddenly appears along a certain definite line, so it as suddenly ceases, and is replaced by a band of forest of about equal breadth, known as the "Bhábar." This tract is almost waterless, and the soil is seen to be chiefly sand or shingle, more or less filled with boulders. The streams that issue from the outer hills on entering the Bhábar are for the most part rapidly absorbed, and finally disappear in their sandy or shingle beds, the water they pour into the soil being again discharged along the outer and lower border of the tract, and collecting once more in the streams which characterize the Tarai.

The Bhábar and Tarai slope continuously from the foot of the mountains to the cultivated plain. The inclination is so uniform as to be hardly perceptible, but becomes gradually less as the distance from the mountains becomes greater. Observation leads us to suppose that the upper part of this talus, lying along the foot of the outer hills, is composed of coarser matter, and the lower part, which comes into view at a greater distance, of a finer and less permeable silt; and that, the latter having a smaller inclination and extending further than the former, the water absorbed by the upper beds will naturally be brought to the surface at their termination, where the finer materials forming clayey strata make their appearance. That the swampy Tarai is not developed in the western part of the range is doubtless due to the smaller rainfall in that region; while its more marked occurrence to the east of the Ganges at irregular intervals arises from the local peculiarities of the surface drainage, which at some places is carried off directly into the larger rivers without check, and in others is forced to follow a line nearly parallel to that of the mountains for considerable distances, through a tract from which there is no free escape for the water; and which, thus becoming water-logged and covered with a rank development of vegetation, acquires its peculiarities, among which has to be reckoned a climate in which fevers of a deadly character are frequently induced, rendering its permanent occupation and cultivation difficult or impossible.

The transition from the plains to the mountains is sudden and well-defined along a line that is almost continuous. The ranges to which geologists have given the name of

"Siwálik," and "sub-Himalayan," rise abruptly, and without any intermediate undulating ground from the apparently level surface of the plain. These hills, which from recent geological investigation we learn to be formed of deposits of various periods of the Tertiary epoch, attain elevations from a few hundred to 3000 or 4000 feet. The dip of the strata composing them is usually at a low angle towards the mass of the mountains, so that they present a steep face to the plains, while a comparatively easy declivity slopes inwards, and frequently, by meeting a corresponding but longer and more gradual talus descending from the foot of the internal line of mountains, forms a shallow, narrow valley which runs generally parallel to the outer range.

These valleys, which are very characteristic of the outer order of the mountains, have by some writers been erroneously confounded with the Tarai. They are termed "Dún" in the western regions; in Nepal they are known by the name of "Mári." Their floors consist of deposits of gravel and boulders, having a maximum elevation of about 2000 or 2500 feet above the sea. Their continuity is broken at intervals by low, transverse, watershed lines, from which the drainage is thrown off along their longitudinal axis, and falls into some of the larger streams which cross them from the inner ranges, though less frequently it finds an independent exit into the plains by a sudden bend to the south through a rupture in the line of outer hills. At intervals these valleys are entirely wanting, and the outer hills which form them elsewhere are undistinguishable from the general mass of mountain within, except through the aid of their geological character. From the considerable elevation of the dún above the plains, down to the level of which the streams which drain them descend in a very short distance, the unconsolidated strata which form the floors of these valleys are often deeply cut into by the watercourses, and present a surface worn into terraces descending in steps of various heights. These conditions lead to a peculiarity which characterizes large parts of the dún, the almost complete impossibility of getting water from wells, due no doubt to the thorough desiccation of the subsoil.

The sub-Himalayan ranges have a well-defined distinct geographical existence along the greater part of the chain, and their geological continuity is established where no valley is formed between them and the inner ranges, and where they cannot be otherwise distinguished from the general mass of mountains. To the west of the Sutlej river these ranges and the valleys connected with them have an unusual development, the width over which they extend increasing from 10 or 15 miles to as much as 50 miles, with a series of two or three dún-like valleys one within another. West of the river Jhelum, again, the aspect of the outer Himalaya is entirely modified by a small tableland, which is formed to the north of the line of elevation known as the Salt range, and extends to the Indus. Its general surface lies at about 1000 feet above the general level of the plain, having a maximum elevation of about 1800 feet, and being remarkable for the extraordinary manner in which it is broken up by ravines, the number, gigantic dimensions, and intricacy of which are alike perplexing and astonishing—the extremely dry climate leading to an almost total want of vegetation, and the absence of any such concealment exhibiting a picture of confusion and desolation not often seen.

The ranges which lie immediately within the external band of the Siwáliks, or sub-Himalaya, rise abruptly above it to much greater elevations, and constitute the first masses which in such a region we can with propriety dignify with the name of mountains. Their ordinary elevation is about 7000 feet, and the highest summits on them reach 8000

laya.

Sketch Map showing the connection between the Himalaya Mountains, and the Tibetan table-land, and their relation to the adjacent plains and mountains. The darkest shade indicates the area the main direction of which exceeds 20,000 feet, the lighter shades show mountain areas of smaller elevation. The open left unshaded areas represent the great plains.

or 9000 feet above the sea. It is on them that sanitary stations have been established for the convenience of the European residents in the neighbouring provinces of India, as affording the nearest sites to the plains at which a temperate climate can be reached. These ranges cover a breadth of about 60 or 70 miles, within which the magnitude of the mountains does not very greatly vary, their crests rarely going above 10,000 feet or falling below 5000 feet. Beyond this again another great change is observed, and the mountains rise rapidly and attain those surpassing heights which place the snow-clad summits of the Himalaya in the foremost rank of all the mountains of the earth.

A remarkable deviation from the normal character of this zone of the mountains is observed to the west of the Sutlej, where, combined with the exceptional extension of the sub-Himalayan ranges already noticed, is found what may perhaps be best described as an outlier of the great central axis of snowy mountains. With a marked change in respect to elevation, as well as in respect to its mineral constituents, the range locally known as the "Dhaola-dhár," or White Mountain, rises directly from the dún of Kángra, the elevation of which is about 2500 feet, into the regions of perpetual snow, its highest points reaching an elevation of 16,000 to 17,000 feet. The same features are prolonged still further to the west beyond the Rávi, and this line of elevation forms the great snow-clad range that shuts in the valley of Kashmir on the south, there known as the Pir-panjál, the general elevation of which is from 14,000 to 15,000 feet, and the passes over it not lower than 10,000 feet.

With this exception the ranges covered with perpetual snow are first met with on the southern slope of the great Indo-Tibetan table-land, along a line between 80 and 90 miles from the foot of the outer mountains, and 20 or 30 miles south of the Indian watershed, and from this line northward snowy peaks abound everywhere over the summit of the table-land. The highest yet measured are near the Indian watershed, but as it is only in this region of the western Himalaya, and in northern Ladák, that any complete survey has been made, it is necessary to be cautious in making statements as to absolute maximum elevation, for the known in these mountains still bears far too small a proportion to the unknown to afford sufficient ground for safe speculation on such a subject.

On the Himalayan slope the loftiest peaks are usually met on the first ranges that enter the limits of perpetual snow, advanced some 20 or 30 miles south of the Indian watershed, and not on a continuous ridge, but grouped in masses separated from one another by deep depressions, through which is discharged the drainage of the tract lying between them and the watershed.

The highest known peak in the Himalaya, and indeed in the world, is that in Nepál known as Mount Everest, which rises to 29,002 feet. Kinchinjinga, in Sikim, on the east, reaches 28,156 feet, and another peak more recently measured, in the extreme west, reaches 28,278 feet. Dháwalagiri, in Nepál, is stated to be 26,826 feet, and Nanda-devi, in Kumaon, to be 25,700 feet above the sea. But many other points have been measured exceeding 25,000 feet in elevation, two of which are to the north of Kumaon; and the enumeration of all known peaks over 20,000 feet would be wearisome. These statements have reference to the particular zone along the Indian watershed above described, beyond which, as was before said, few measurements have been made (excepting in Ladák), but there is every reason to believe, from such scanty facts as are available for forming an opinion, that mountains rising considerably above 20,000 feet are of frequent occurrence throughout Tibet.

To give a more precise idea of the character of the snowy zone, it will be worth while to state somewhat in detail the distribution of the great peaks which lie between the 78th and 81st meridians, in the provinces of Kumaon and Garhwál, which have been far better surveyed than any other part of the range. On a line of something less than 150 miles in length are found six great snowy groups, with five great rivers passing between them:—(1) on the east is the cluster of Api in Nepál, with a peak of 22,700 feet; (2) Yirnajang, between the Dárma river and the Káli, rising to 21,300 feet; (3) the Páñch-chuli group, between the Dárma river and the Gori, with a maximum of 22,700 feet; (4) the great compound mass which lies between the Gori and the Dhaoli rivers, consisting of Nanda-devi, Nanda-kot, Dunagiri, and Trisál, the first reaching 25,700 feet, the second 22,600 feet, the third 23,200 feet, and the last, having a length of more than 10 miles, no part of which is under 20,000 feet, its central point reaching 23,400 feet above the sea; (5) the peaks between the Dhaoli and Vishnuganga rivers, three of which lie between 22,300 and 22,600 feet; (6) the great group of Badarináth, Kedárnáth, and Gangotri, between the Alaknanda and Bhágirathi, the chief feeders of the Ganges, the first mass rising to 22,400 feet and the second to 22,900 feet, while the third has five points varying in height between these. All these masses are connected with the main watershed by ridges more or less covered with perpetual snow, on which have been measured two other peaks rising above 25,000 feet, several others reaching 23,000 feet, and many more between 19,000 and 20,000 feet. There is no reason for thinking that this gives an exaggerated idea of the vast scale on which these mountains are developed. There can be little doubt that as precise knowledge is advanced the number of peaks between 25,000 and 30,000 feet will be found to be very much extended; nor will it be surprising if points are eventually discovered exceeding 30,000 feet in altitude.

The average elevation of the crest of the Indian watershed, between the points where the Indus and Brahmaputra cross it, a distance of some 1500 miles, most probably exceeds 18,000 feet. At a comparatively few points only its continuity is broken, and it allows the passage of rivers that rise on its northern flank; but at all other parts its summit must be crossed to enter Tibet from the south. The passes over it, in ordinary use for men and animals, are frequently more than 18,000 feet above the sea, and except where it is broken through as just mentioned, one point only is believed to exist at which it can be surmounted under 16,400 feet. This pass, which leads directly from Kashmir into the Tibetan district of Drás, is only 11,300 feet, and is quite anomalous; such a depression elsewhere would have been sufficiently deep to open a passage for the drainage of the table-land, but the great depth of the valley further north, in which the Indus flows, here gives the waters a more favourable escape in that direction.

The valleys which traverse the mountains between the plains and the great watershed are for the most part little more than gigantic ravines, at the bottom of which flows the river each contains, in a very contracted bed which at rare intervals opens out into a narrow alluvial flat capable of cultivation. The level of the river beds is necessarily very various. Valleys only 2000 or 3000 feet above the sea are often opened up into the very heart of the mountains, and carry with them the heat and vegetation of the tropics among ranges the summits of which are capped with eternal snow. In tracing up the larger streams it is usually found that on arriving within 10 miles of the line of the great peaks the rivers are flowing at an elevation of little more than 4000 or 5000 feet, but on crossing that line the acclivity suddenly and rapidly increases, and the

river-beds in a very few miles are found to be at an altitude of 9000 or 10,000 feet, indicating that the sudden increase to the height of the mountains along this line is not confined to the peaks alone, but consists of a general elevation of the whole surface. Having once crossed the line of great peaks, the inclination of the valleys again becomes much less, and they thus continue for some miles, those that are fed from the larger glaciers frequently emerging from the ice at a level no more than 12,000 feet above the sea in the western mountains, 1000 or 2000 feet higher on the east.

The slope of the larger Himalayan rivers may be estimated to range from 20 feet per mile near the plains to between 100 and 200 feet per mile where they approach the snowy mountains. In their passage through these the inclination increases to as much as 700 or 800 feet in the mile, but to the north it is again reduced to 150 or 200 feet. Like all Indian rivers, they vary greatly in volume at different seasons of the year, and among the higher mountains are liable to special fluctuations from the more or less rapid melting of the snow from which they are fed. In the summer their waters increase and decrease with the varying temperature of the day or power of the sun, and in the winter they contract to a small fraction of their summer volume as the permanent frosts set in. In the lower parts of their courses the rivers commonly present an alternation of sparkling rapids with long reaches of deep, clear, tranquil water, in which the action of the current is often hardly visible; as we ascend, the rapids become by

degrees more frequent and more impetuous, till in passing among the snowy mountains we find only the most furious torrents, pouring their turbid glacier waters over boulders of gigantic dimensions among which they are at times almost lost to view, and filling the valleys with their incessant roar.

The valleys of Kashmir and Kathmándu, by their exceptionally large extent and comparatively level character, offer such remarkable deviations from the normal characters of Himalayan valleys as to require some comment. But the differences are after all rather in degree than in kind, and it would not be difficult to find somewhat similar areas, though on a much smaller scale of development. In Kashmir, too, is found one of the very few lakes which occur in the Himalaya. The almost complete absence of such collections of water is among the circumstances which serve to give a special character to the scenery of the Himalaya, and to distinguish it from that of European mountains.

On crossing the Indian watershed into Tibet, the general character of the country completely changes. The summit of the table-land, though deeply corrugated with valleys and mountains in detail, is in its general relief laid out horizontally at a mean height little inferior to that of the watershed itself. The valleys of central Tibet are commonly long, flat, and open, of no great breadth, perhaps 1 to 3 miles, with a bottom of alluvial soil laid out nearly horizontally, from which the mountains rise abruptly on either side. The plateau of Gugé, immediately to the north of Kumaon,

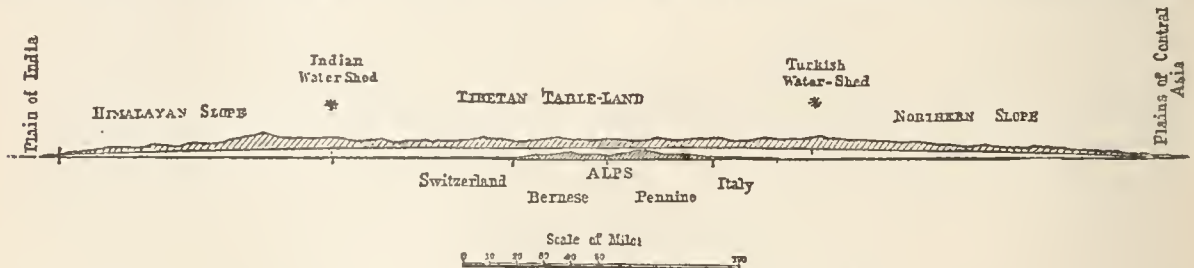

FIG. 1.—Sections of the Alps and of the Himalaya on the same scale.

the average elevation of which is not less than 15,500 feet above the sea, and at the extremity of which lie the two lakes of Rákas-tál and Mánasarowar, the waters of which are also nearly at that level, is a remarkable expansion of the ordinary Tibetan valley, and calls for special notice. It varies in breadth from 15 to 60 miles, and its extreme length is 120 miles, lying along the upper course of the Sutlej, which runs through it at the bottom of a stupendous ravine furrowed out of the alluvial matter of which the plateau is formed, to a depth of 2000 or 3000 feet. Into this run, across the western part of the plain, numerous other similar ravines in every gradation of size, often for miles together as even and straight as a railway cutting; and so extraordinary is their magnitude in some cases that, in his account of a journey across the plateau, Moorcroft, a traveller of great accuracy in general, describes these slopes as those of mountains.

The main valleys are everywhere remarkable for their gentle slope, and in the central parts of the table-land the inclination at length frequently becomes so small as to give rise to the accumulation of the drainage in lakes, invariably salt when there is no efflux, and as invariably fresh when there is. The upper Indus has a slope as little as 3 feet per mile. Further to the west, as it approaches its great bend to the south, the inclination becomes greater, averaging about 24 feet per mile, and the width of its valley floor is reduced. It descends to a level of little above 4000 feet before it finally leaves Tibet.

It may aid in conveying a clear conception of the magnitude of these Himalayan masses, to compare them with the Swiss Alps, which will be familiar to many English readers. The above diagram represents on the same scale sections of the Alps and of the Himalaya, the curved line from which the latter are shown to rise representing the curvature of the earth. The Alps, measured across from the Lake of Thun to the plains of Lombardy, have a width of about 75 miles, the Tibeto-Himalayan mountains on a line drawn through Simla being about 400 miles across. To complete the comparison a few further explanations may be offered. The range that has already been noticed as the Dhaola-dhár, which rises from the Kángra dún, if measured in breadth from Kángra to the upper Rávi, and in length between that river and the Byás in Kullú, is about equal to the whole of the Bernese Alps comprised between Altdorf and Martigny in length, and laterally between lines drawn along the Rhone and Reuss on one side, and through the Lakes of Lucerne and Thun to the Lake of Geneva at Vevay on the other. The area covered in both cases is rather less than 100 miles in length by 20 or 25 in breadth, the highest peaks being in the Alps the Finsteraarhorn, 14,100 feet, and in the Dhaola-dhár a point 17,100 feet above the sea. The prolongation of the Himalayan ridge just spoken of, which bounds Kashmir on the south, known as the Pir-panjál, would in like manner compare with the Pennine Alps and their continuation as far as St Gothard. Here the peak

of Mont Blanc, 15,750 feet, slightly exceeds the highest point of the Pir-panjal, which is but little over 15,500 feet, though, with this single exception, the Kashmir range certainly much exceeds in general mass that of the portion of the Alps compared with it. To obliterate these two ranges from the Himalaya would make no very sensible inroad on it, though they surpass in bulk the whole of the Swiss Alps; and it is no exaggeration to say that, along the entire range of the Himalaya, valleys are to be found among the higher mountains into which the whole Alps might be cast without producing any result that would be discernible at a distance of ten or fifteen miles. And it is important to bear in mind these relations of magnitude, for the terms at our disposal in the description of mountains are so limited that it is necessary to employ the words chain, range, ridge, spur, &c., rather with reference to relative than to absolute importance, so that the scale of our nomenclature changes with the extent and altitude of the mountains of which we speak.

Surface drainage of Himalaya : how determined. An examination of the maps of the Himalaya indicates that throughout their whole extent a constant tendency is discernible for the rivers to flow either parallel to the general direction of the part of the chain through which they run, or perpendicular to it,—many or perhaps most of them combining both tendencies, and running first in the one direction and then in the other. The conclusion is hence suggested that the system of surface drainage is determined by a series of longitudinal and transverse lines of rupture along and across the mountains. The study of the rivers and mountains themselves confirms this view. In many cases an apparent diagonal direction is found to be really due to a succession of short abrupt bends, though no doubt the rivers at times actually take an oblique course across the mountains. Frequently, too, where a river changes from a longitudinal to a transverse direction, another longitudinal stream meeting the first flows down from an exactly opposite direction. The same disposition is otherwise often exhibited by the occurrence of both transverse and longitudinal lines of drainage, or valleys, starting in opposite directions from the same point on the main ranges, while a depression occurs in the ridge at the point whence such valleys take their departure.

Arrangement of mountain features. As the rivers and ridges that separate them must be laid out on the same general plan, it is natural to find in these last the same tendency to follow lines perpendicular, or parallel, to the general direction of the chain. There is no part of the mountains in which these peculiarities may not be traced, the longitudinal character prevailing on the summit of the table-land, and the transverse being dominant on the Himalayan slope. By the combination of these tendencies the rivers flow to the plains along a line generally oblique to the component parts of their actual course; and the watershed ridges that separate them follow corresponding directions. But such watershed lines rarely have any true structural continuity, however strongly they may be marked on our maps, and great caution must be exercised in inferring physical relations among such features of the mountains without obtaining some knowledge of their geological structure.

Considering the vast extent of these mountains, and the material and political difficulties in the way of the traveller who visits them, it is not surprising that the knowledge of their geological structure is still very imperfect. From causes which are not very obvious, important parts of the deposits of which they consist have till now not yielded any fossil remains by which their age can be determined; the visits of qualified geologists to the more remote parts of the chain have been very rare; and it is only within the last few months that any connected memoir on the subject has been published. Much that has been

written on it is of too speculative a nature to find place in such an account as the present, and all that can be attempted is a brief outline of the main conclusions that seem established.

Of the great Indian plain nothing very definite can be said. It is an alluvial deposit of sandy clay, on the surface of which nothing in the shape of a pebble can be found excepting in the immediate vicinity of the hills that rise from it. In one place alone, in the north-west, on the Jumna river, have fossil remains been found imbedded in it, at some depth below the surface. They belonged to terrestrial mammals, with fish and crocodiles, which seem to be of the post-Tertiary epoch. A few borings have been made to depths of some hundreds of feet, but they throw no great light on the subject of the origin of the plain. There is no direct evidence either for or against its having been laid out by the sea; on the one side it seems difficult to understand how so even a surface could have been produced otherwise than under the sea, while on the other there is a complete want of marine remains both in the alluvium itself and in the most recent deposits which form the hills that rise from it. It seems to be admitted that some parts of the alluvial plain of the Indus have been submerged, and in any case, if it was produced by river action, it must have been by rivers having a very small inclination, and in a delta, or at a low elevation.

The outermost ranges of the sub-Himalaya are also geologically the most recent. They are composed of grey micaceous sandstones, generally very soft and often quite unconsolidated, with beds of red and blue clays and marls interspersed, and boulder and gravel beds, at times hardly to be distinguished from those formed in the existing rivers, and often cemented by carbonate of lime into conglomerates. Though these formations are most strongly developed to the west, they have been observed in Nepal and also in Bhotán. It is from the ranges in the vicinity of the Jumna river that the characteristic Siwalik fossils have chiefly been obtained. They consist of numerous species of mammals and reptiles, with a few fish, birds, and mollusca,—all, however, remains of land or freshwater animals, with no certain trace of marine creatures. Lignite occurs in thin isolated beds in small quantities. It had been commonly supposed that the Siwalik fauna was of Miocene age. The later views rather point to its being Pliocene. Sixteen genera among the fossil remains have not been found in any beds older than Pliocene, and of the many genera which continue to the present time, some of the forms preserved in these fossils are remarkably similar to existing species, all of which indicates a closer relation to the more recent than to the older Tertiaries.

In close juxtaposition with this external band, but connected geologically in a manner that has not been very clearly established, is an older series of beds, the lowest of which is nummulitic and of the oldest Tertiary epoch. The fossils found in these beds are as markedly marine as those of the other series are terrestrial. The junction of the newer with this more ancient series is concealed by disturbances, and the former has not been found overlying the latter, but only abutting upon it. This older section of the Tertiary beds of the sub-Himalaya has only been properly made out to the west of the Jumna, though it is likely that it is also represented in the central and eastern parts of the chain by certain sandstones which occur there at the foot of the higher mountains. It may be surmised also that the nummulitic beds of these ranges are connected on the one side with those which are found to the west of the Indus extending to Sindh, and on the other with the nummulitic rocks of the hills south of Assam.

A complete change of geological character occurs on

The
outer
parts of
main
chain.

passing from these outer and lower ranges to those higher mountains which extend to the line of snowy peaks. On the west of the chain the first of these ranges consists of argillaceous shales and schists, grits and limestones, intersected by several lines of igneous action, and all devoid of fossil remains. True slates also occur. The stratification is everywhere well marked, the dip being usually towards the interior of the chain at an angle of from 10° to 20°. Portions of the mountains are found in which the dip is quite reversed, or towards the plains, a result no doubt of absolute rupture and partial dislocation. The lines of igneous action follow generally the line of strike, the type of the rock being greenstone, and conglomerates or breccias being often associated with it.

How far these beds extend to the eastward is somewhat in doubt. Suggestions have been made that they are the representatives of the Silurian or other fossiliferous beds found to the north of the great snowy mountains, but the evidence for this is hardly conclusive. The occurrence at the foot of the mountains in Sikim and Bhotán of a deposit containing fossil coal-plants, which are apparently identical with those of the Bengal coal-field, renders it probable that the rocks there are of the age of that coal, that is to say, of the lower Trias, a conclusion which somewhat serves to corroborate the speculation as to the age of the western beds just referred to.

Lines of
granite
and
other
igneous
rocks.

In certain parts of this outer region of the mountains granite also occurs, accompanied by gneiss and mica-schist, the latter often abounding in garnets. In mineralogical character this granite and its accompanying schists differ greatly from those of the great peaks, which are also formed of granite and schists; this has suggested a possible difference of age, and it remains uncertain whether any or what connexion exists between them.

The
snowy
mountains.

As we approach the line of great peaks the rocks pass into highly crystalline gneiss or mica schist, and another more continuous line of granite intrusion occurs, divided into several branches, but distributed generally on the line of strike, that is, along the principal direction of the chain itself. It is chiefly in veins, though it expands at times into masses of considerable size, and more rarely into outbursts large enough to constitute whole mountains. The general dip of the strata continues throughout this area to be directed inwards, its angle being increased to as much as 45°, though seldom to more than that. Beds of highly crystalline limestone, some pure, and some not easily distinguished from the gneiss or mica schist among which they occur, are common along a band following the direction of the strike. The vein granite is usually large-grained; hornblende at times replaces the mica; the felspar is invariably white, and crystals of schorl and kyanite are frequently seen in it.

The great peaks are, with few exceptions, composed of schistose rock, though granite veins may be seen in the mountain faces to very great elevations; one of these exceptions is the great peak of Kámet in Kumaon, which rises to about 25,000 feet in what appears to be a mass of grey granite.

Passing to the north of the line of great peaks the metamorphosed schists are suddenly replaced by slates and limestones, which are in many places highly fossiliferous, exhibiting what appears to constitute in the aggregate a fairly continuous series from the Lower Silurian to the Cretaceous formations, though the complete sequence has not been observed in any one locality. The western region of the Himalaya alone has been sufficiently explored to admit of any positive statements, but the indications gathered from such imperfect accounts and other data as exist relative to the eastern parts of the mountains leave little doubt that the change observed in the west on approaching and enter-

ing Tibet holds good on the east also, and that the general physical features of the whole tract are much alike, though doubtless with many differences in detail.

The fossiliferous strata of western Tibet are continued, though perhaps with some breaks, to the Tertiary period. In certain localities nummulitic rocks, probably Eocene, have been observed, and from the great alluvial deposit which forms the plain of Gugé, already noticed, the remains of mammals, apparently of Siwalik age, have also been obtained. Among these were bones of the elephant and the rhinoceros, the existence of which, in the present condition of these regions, would be wholly impossible; so that there is no room to doubt that these deposits have been raised from a comparatively low level to their existing great elevation of upwards of 15,000 feet, since they were laid out. As in the case of the plain of India, we here, too, have no complete proof of the origin of these great nearly horizontal deposits, but it seems clear, from the materials of which they are formed, that they must have been laid out by water, either by the sea or some great inland lake. They are largely composed of boulder deposits, and large boulders are strewn over the surface imbedded in the ground in a manner that seems only explicable as the result of the action of a considerable body of water.

Several lines of granitic and eruptive rock occur in western Tibet, of which all that need here be said is that they appear all to be older than the Tertiary alluvium, but some of them are possibly contemporaneous with the nummulitic and older formations.

The general conclusion that may be drawn from the facts of structure thus briefly indicated is that the elevation of the Himalaya to its present great height is of comparatively recent occurrence. An area of land must have existed where the main line of snowy peaks now stands, which has not been submerged since the Palæozoic period, and which then had its northern boundary somewhere along what has been termed the Indian watershed. Evidence of a similar ancient sea on the south also exists, but in a less definite shape; and whether it was united with the northern sea or not is still a matter of conjecture, though the distinctive character of the fossils rather indicates that there was no direct union. The possible connexion of this ancient Himalayan land area with the pre-Tertiary land of the peninsula of India is also only a matter for speculation.

There is further reason to infer that the existence of the great line of peaks is rather due to some previous line of elevation on the ancient land, which has continued to retain its relative superiority while the whole area has been raised, rather than to any special line of energy of upheaval of recent date; and that the fundamental features of its former configuration of surface in mountain and valley have been preserved throughout. There is evidence for the conclusion that the chief rivers of the pre-Tertiary land issued from the mountains where the present main streams are found, and this embryo Himalaya may have been of such moderate height as to have permitted the passage across it of the Siwalik mammals, the remains of which appear both on the border of the Indian plain and in Tibet. It is after the middle Tertiary epoch that the principal elevation of these mountains must have taken place, and about the same time also took place the movements which raised the table-lands of Afghanistan and Persia, and gave southern Asia its existing outlines.

The best answer that can be given to an inquiry as to how changes of level could have arisen, such as those which are observed in the Himalaya, is that they should be regarded as due rather to secondary actions consequent on the general contraction of the cooling terrestrial sphere than to direct elevating forces, for which no

known origin can be assigned. The contraction of the cooling but now solid crust of the earth must have set up great horizontal strains, partly of tension and partly of compression, which would necessarily have been followed by rupture or crushing along lines of least resistance, and the movements on such lines are marked by the great mountain ranges that traverse the surface. A dislocation of the solid crust of the earth once having taken place, it would probably continue to be a line of least resistance ever after, and a succession of movements during past geological periods may thus be reasonably expected along such lines. Somewhat in proportion as the disturbing forces are intense, and the thickness of the crust on which they act is great, will be the tendency for the lines of rupture to be continuous for a considerable distance; and as the disturbed area is extended in its dimensions, the probability will increase of a repetition of a series of similar dislocations on lines approximately parallel to, or at right angles to, one another, and to the line on which the greatest compression and consequent tension take place. In a disturbed area, one transverse dimension of which is sensibly greater than the rest, the longitudinal ruptures will predominate in the interior and the transverse towards the borders. Almost all mountains give indications of having been shaped by forces thus related, and to the action of such forces may the main characteristics of the structure of the Himalaya, and the arrangement of its ridges and valleys, be attributed. Whatever may be the power of rivers in general as instruments of erosion, and whatever effect the Himalayan rivers have had in removing the fragments of the rocks over and among which they took their courses, it is hardly possible to doubt that their main directions were determined by the anterior lines of dislocation which opened up hollows down which they could flow, and which must invariably have been accompanied by a destructive and crushing action on the rocks along them, which has enabled the waters the more readily to sweep away the obstacles in their path. The parallelism of many of the great Tibetan and Himalayan rivers for hundreds of miles together, amid such mountains, seems wholly inexplicable in any other manner.

Although the loftiest mountains when compared to the earth's diameter are insignificant in their dimensions, and the irregularities of the surface would hardly be perceptible on any sphere, however large, that could be made to represent the earth, yet in relation to the depth of the atmosphere even moderate elevations become of great importance, and such heights as those reached by the Himalaya introduce modifications of climate in ascending over its slopes that are not surpassed by those observed in moving from the equator to the poles. One half of the total mass of the atmosphere and three-fourths of the water suspended in it in the form of vapour lie below the average elevation of the Himalaya, and of the residue one half of the air and virtually almost all the vapour come within the influence of the highest peaks.

The general changes of pressure of the atmosphere indicated by the barometer extend in a modified but well-marked manner to the greatest elevations to which observation has been carried, and the annual and diurnal oscillations are not less regular in Tibet than in the plains of India, though somewhat reduced in amount. With the increase of elevation the diminution of the quantity of vapour held in suspension is very marked, and at the greatest heights reached there is found not more than one-sixth or one-seventh part of that observed at the foot of the mountains, and the proportion is sometimes as low as a tenth, or less. As is well known, the maximum quantity of water that can be suspended in the air in a state of vapour depends on the temperature of the air, and observa-

tion has established that the actual quantity at all elevations is approximately proportionate to this maximum, and is thus determined by the temperature, which in turn is regulated by the elevation. The theoretical view once held that watery vapour was distributed in the atmosphere in accordance with the laws of pressure of elastic fluids is manifestly inconsistent with observed facts, which indicate that the diffusion of vapour is powerfully obstructed by the air particles, and that it by no means behaves as an independent elastic fluid, but rather as though it were merely mixed up with or entangled among the air particles.

The great elevations to which the Himalaya ascends, and the broad zone which it covers in respect to latitude, and its varying distance from the sea necessarily lead to correspondingly great variations of climate in its different parts, including the temperature and the degree of humidity in the atmosphere, and the amount of rainfall. The general position of the whole tract between the 25th and 35th degrees of north latitude renders it subject to high summer temperatures. The heat of the great plain of northern India is not surpassed at any other part of the earth, the air temperature rising in the hottest months to more than 110° Fahr.; the fall of temperature in the winter is considerable, the thermometer receding at times to the freezing point, or even a little below it; the mean temperature varies from 78° Fahr. in the east or southern portion to 75° in the west or north. On the mountains every altitude has its corresponding temperature, an elevation of 1000 feet producing a fall of about 3½°, or 1° Fahr. to 300 feet. The mean winter temperature at 7000 feet is about 44° Fahr., with a mean minimum of 32° Fahr., and the summer mean about 65° Fahr. At 9000 feet the mean temperature of the coldest month is 32° Fahr., at 12,000 feet the thermometer ceases to fall below freezing point from the end of May to the middle of October, and at 15,000 feet it is seldom above that point at the coldest part of the day in the height of summer. There seems to be less variation of temperature at equal altitudes on the mountains in passing from east to west than might have been expected from the greater winter cold of the western part of the plains. This is probably due to the greater relative humidity and heavier rainfall of the eastern regions, and the denser vegetation which covers them. These influences tend to keep down the day temperature on the eastern mountains, while the clearer skies and more open character of the west operate in the opposite direction. On the more woody and rainy mountains in the outer parts of the chain the mean summer temperature will be 60° at 10,000 or 11,000 feet, but it will still be as much as that up to 12,000 feet, or even to a greater elevation, in the bare and sunny valleys near the Indian watershed.

In Tibet the thermometrical conditions vary considerably from those of the Himalayan slope. At 12,000 feet the maximum temperature is perhaps 70° Fahr. and the absolute minimum 5° Fahr. The ordinary winter temperature is from 0° Fahr. to 30° Fahr., with a mean of the coldest month of 10°. The mean of the hottest month is about 60°, and of the year 35°. At 15,000 feet the frost is permanent from the end of October to the end of April, and the lakes are usually frozen over for nearly five months in the year. Between 15,000 and 16,000 feet the thermometer will fall below the freezing point every night of the year. At heights of 17,000 or 18,000 feet it rises considerably above that point in the summer months. From 18,000 to 19,000 feet it thaws only in the afternoons of July and August; and at 20,000 feet there is probably perpetual frost in the shade, though in the sun the air no doubt rises above the freezing point to much greater elevations. Of Tibet.

All the rivers in Ladák are frozen over every winter down to 8000 feet, a phenomenon that has been nowhere seen in the Himalaya, the rivers that are accessible during winter being at too small an elevation to be ever frozen, and the main streams probably everywhere too rapid.

The diurnal range of temperature is directly dependent on the condition of the surface and the state of the sky. On all well-wooded ranges it is very small, particularly in the cloudy and rainy months, when it will not exceed 5° or 6°. In the dry months of April or May, before the summer rains begin, and in the autumn when clear skies again prevail, the variation is greatest. In Tibet it is greatest in summer and least in winter, which is the most cloudy season. The annual variation follows a similar law, 20° being about the minimum mean monthly range on the wooded outer mountains, while in Tibet it amounts to as much as 50°.

Comparison of eastern and western parts of chain.

The difference of temperature between ranges densely clad with forest and the Indian plains may be twice as much in April and May as in December or January; and the differences between the temperatures of a well-wooded hill-top and an open valley below have been observed to vary as much as from 9° in the coldest to 24° in the hottest hour. Precisely the converse may be found to hold good in comparing greater altitudes in Tibet with lesser in the Himalaya, where the humidity is greater.

General relation of temperature to altitude.

It is generally true here as elsewhere—(1) that the decrement of temperature with altitude is most rapid in summer; (2) that the annual range diminishes with elevation; and (3) that the diurnal range also diminishes with elevation. But the greater quantity of cloud and the more dense covering of forest between 9000 and 10,500 feet render comparisons between this zone and the more open and less cloudy regions above and below anomalous, for reasons that will be apparent after the above remarks.

Rainfall: periodicity, how caused.

The chief rainfall on the Himalaya, like that of India generally, occurs in the summer months between May and October, the remainder of the year being comparatively dry. The physical causes which give rise to the south-west monsoon, under which name is known the season of summer rain as well as the south-westerly winds which accompany it, have been sufficiently explained in the article on ASIA, to which the reader is referred for further details.

General distribution.

The fall of rain over the great plain of northern India gradually diminishes in quantity, and begins later, as we pass from east to west. At the same time the rain is heavier as we approach the Himalaya, and the greatest falls are measured on its outer ranges; but the quantity is again much diminished as we pass onward across the chain, and on arriving at the border of Tibet, behind the great line of snowy peaks, the rain falls in such small quantities as to be hardly susceptible of measurement.

An important agent in distributing the rain which falls over the Himalaya, if indeed it be not the essential one, is found in the diurnal currents of wind which are established from the plains towards the mountains, and *vice versa*, blowing up the valleys towards the main watershed from about 8 A.M. to 8 P.M., and in the opposite direction during the corresponding hours of the night. These diurnal winds, which are a very striking phenomenon, and blow in the afternoon with great force along the Himalayan and Turkish watersheds and the neighbouring parts of the plain of Tibet, are common to all mountains, and are no doubt due to the disturbances of the planes of equal atmospheric pressure in a direction transverse to the mountains, caused by the unequal diurnal expansion and contraction of the columns of air respectively over the plains and mountains, the former being obviously longer than the latter, so that the planes of equal pressure are lifted by expansion higher over the plains during the day, and depressed by contraction

during the night, thereby setting up currents to and from the highest region of the mountains as these alternating actions take place.

The condensation of vapour from the ascending currents thus set up across the Himalaya from the Indian plain, and their gradual exhaustion by repeated precipitations as they cross successive ranges, is manifested to the traveller on the face of the mountains themselves, by the changes observed in the vegetation on passing to leeward of any important range, and more especially the line of great snow peaks. In the rainy months in the higher parts of the chain the southern face of each ridge is clothed by the day upwind with a crest of cloud, which hangs upon it, the northern face being often left entirely free, thus showing how large a portion of the vapour is arrested, and showing also that it is only up the deeper gorges that a small supply of moisture finds its way to the Tibetan table-land.

The yearly rainfall, which amounts to between 60 and 70 inches in the delta of the Ganges, is reduced to about 40 inches where that river issues from the mountains on the 78th meridian, and is no more than 30 inches near the foot of the mountains at the issue of the Indus. At Darjeeling, at about 7000 feet on the east, on the outer border of the mountains, it amounts to about 120 inches; at Nainital, at about the same elevation and similarly situated in 79½° E. long., it is about 90 inches; and further west it is still more reduced in quantity. In passing from the exterior to the interior of the chain the quantity greatly diminishes. In Kumaon, while in three months 49 inches was registered at Nainital on the outer range, only 19 inches fell at Almora, at 5600 feet, 30 miles further in. At Joshimath, 50 miles onward and close under great snowy peaks, at 6500 feet, 22 inches were measured in the same period; while at Niti, 11,500 feet behind the snowy peaks, the fall did not exceed 5½ inches. In a week of rainy weather, when 1½ inches fell at Joshimath, half an inch was measured at Niti; while beyond the Tibetan watershed during the same period the rain fell in a very faint drizzle which could not be measured at all. Similar facts might be quoted from the eastern mountains.

In the eastern Himalaya the ordinary winter limit of snow is 6000 feet, and it is rare for even 3 inches to remain as many days on the ground on a southern exposure at 7000 feet. In Kumaon, on the west, it is pretty certain that snow will fall every year at about 6500 feet, and at 5000 feet it will not fail one year out of ten; the lowest level to which sporadic snowfalls are known to descend is about 2500 feet, of which two or three instances have occurred in the present century. At Peshawar, at an elevation of a little above 1000 feet, snow occasionally falls, but very rarely. At Lé, in western Tibet, the results of two years' observations indicate that the depth of snow that falls is less than 2 feet, the heaviest continued fall measuring 8 inches and lasting three days, at an elevation of 12,500 feet. Depths of 3 feet have been measured on passes between 17,000 feet and 19,000 feet above the sea. On the Indian watershed the falls are much heavier, and even in September the passes are sometimes quite blocked by the falls which commonly occur after the equinox, and they are not usually open again till the middle of June.

It is now satisfactorily established that the snow line, or the level to which snow recedes in the course of the year, ranges from 15,000 to 16,000 feet on the southern exposures of the Himalaya that carry perpetual snow, along all that part of the chain that lies between Sikim and the Indus. It is probably not till December that the snow begins to descend for the winter, though after September light falls occur which cover the higher mountains down to 12,000 feet, but these soon disappear. On the Indian

watershed the snow line is not lower than 18,500 feet, and on the summit of the table-land it reaches a height of about 20,000 feet. On all the higher passes into Tibet the vegetation reaches to about 17,500 feet, and in August they may all be crossed in ordinary years, even up to 18,400 feet, without finding any snow upon them; and it is as impossible to find snow in the summer on the great plain of Gugé in western Tibet, at 15,500 feet above the sea, as on the plains of India.

There was at one time much discussion as to the true cause of the level of the snow line being higher in Tibet than on the outer ranges of the Himalaya. But the reason is obvious, namely, the greater quantity of snow that falls on the exterior ranges. The snow line marks the limit beyond which some snow always remains unmelted, that is, the point where on the average of years the summer heat will destroy the winter's snow. The main element in determining such a point will evidently be the quantity of winter snow that falls, the summer heat being not very different over the whole area. That the fall of snow on the outer ranges is greater than it is nearer the watershed at the same elevation is beyond doubt, and the smaller quantity of snow is more easily and earlier melted.

Glaciers.

It was long affirmed that there were no true glaciers in the Himalaya, and ingenious arguments were adduced to account for their absence. But, in fact, they abound along all the higher ranges precisely in those circumstances under which they are found elsewhere, and all the phenomena observed elsewhere in connexion with them are reproduced in these mountains.

Elevations at which found.

The level to which the Himalayan glaciers descend is very various, being greatly dependent on local conditions, principally the extent and elevation of the snow basins which feed them, and the slope and position of the mountain on which they are formed. A glacier formed on the southern face of the Himalaya may readily be in a position in which it might, with a length of 10 miles, descend from 18,000 feet to 11,500 feet. But in Tibet, or in the highest valleys, it might as readily happen that in 10 miles no lower level than 16,000 feet could be reached. With a larger snow basin on the south the greater waste in reaching the lower level might easily be compensated, while no conceivable supply would enable the Tibetan glacier to reach 11,500 feet, to do which it must extend perhaps 100 miles. These considerations will sufficiently explain the fact that the glaciers on the outer slopes of the Himalaya descend much lower than is commonly the case in Tibet, or in the most elevated valleys near the watershed. The glaciers of Sikkim and the eastern mountains are believed not to reach a lower level than 13,500 or 14,000 feet. In Kumaon many of them descend to between 11,500 and 12,500 feet. In the higher valleys and Tibet 15,000 and 16,000 feet is the ordinary level at which they end, but there are exceptions which descend far lower. In Europe the glaciers descend between 3000 and 5000 feet below the snow line, and in the Himalaya and Tibet about the same holds good. The summer temperatures of the points where the glaciers end on the Himalaya also correspond fairly with those of the corresponding positions in European glaciers, viz., for July a little below 60° Fahr., August 58°, and September 55°.

Their movement.

Measurements of the movement of Himalayan glaciers have been made which also give results according closely with those obtained under analogous conditions in the Alps, viz., rates from 9½ to 14¼ inches in twenty-four hours. The motion of one glacier from the middle of May to the middle of October averaged 8 inches in the twenty-four hours. The average yearly motion of the glacier of the Aar is said to be 7½ inches in twenty-four hours. The dimensions of the glaciers on the outer Himalaya, where,

as before remarked, the valleys descend rapidly to lower levels, are fairly comparable with those of Alpine glaciers, though frequently much exceeding them in length—8 or 10 miles not being unusual. In the elevated valleys of northern Tibet, where the destructive action of the summer heat is far less, the development of the glaciers is enormous. At one locality in north-western Ladák there is a continuous mass of snow and ice extending across a snowy ridge, measuring no less than 64 miles between the extremities of the two glaciers at its opposite ends. Another single glacier has been surveyed 36 miles long.

In connexion with almost all the Himalayan glaciers of which precise accounts are forthcoming are found ancient moraines indicating some previous condition in which their extent was much larger than now. In the east these moraines are very remarkable, extending 8 or 10 miles. In the west they seem not to go beyond 2 or 3 miles, and they have been observed on the summit of the table-land as well as on the Himalayan slope. The explanation suggested to account for the former great extension of glaciers in Norway would seem applicable here. Any modification of the coast-line which should submerge the area now occupied by the North-Indian plain, or any considerable part of it, would be accompanied by a much wetter and more equable climate on the Himalaya; more snow would fall on the highest ranges, and less summer heat would be brought to bear on the destruction of the glaciers, which would receive larger supplies and descend lower. Such an explanation is not inconsistent with what is known of the geological formation of the mountains, and appears to be otherwise supported by the evidence of a greater former extension of the lakes of Tibet, and of the former existence of rivers flowing from the Himalaya between the Jumna and the Sutlej, the dry beds of which are now to be traced, in which water is never seen. Till now no geological evidence has been adduced to indicate in this region anything corresponding to the glacial epochs of northern Europe, to which these former extensions of the glaciers could be attributed.

Botany. General characteristics of flora.

Speaking broadly, the general type of the flora of the lower, hotter, and wetter regions, which extend along the great plain at the foot of the Himalaya, and include the valleys of the larger rivers which penetrate far into the mountains, does not differ from that of the contiguous Malayan peninsula and islands, though the tropical and insular character gradually becomes less marked as we pass from east to west, where, with a greater elevation and distance from the sea and higher latitude, the rainfall and humidity diminish and the winter cold increases. The vegetation of the western part of the plain and of the hottest zone of the western mountains thus becomes closely allied to, or almost identical with, that of the drier parts of the Indian peninsula, more especially of its hilly portions; and, while a general tropical character is preserved, forms are observed which indicate the addition of an Afghan as well as of an African element, of which last the gay lily *Gloriosa superba* is an example, pointing to some previous connexion with Africa.

The European flora, which is diffused from the Mediterranean along the high lands of Asia, extends to the Himalaya; many European species reach the central parts of the chain, though few reach its eastern end, while genera common to Europe and the Himalaya are abundant throughout and at all elevations. From the opposite quarter an influx of Japanese and Chinese forms, such as the rhododendrons, the tea plant, *Aucuba*, *Helwingia*, *Skinimia*, *Adamia*, *Goughia*, and others, has taken place; these being more numerous in the east and gradually disappearing in the west. On the higher and therefore cooler and less rainy ranges of the Himalaya the conditions of

temperature requisite for the preservation of the various species are readily found by ascending or descending the mountain slopes, and therefore a greater uniformity of character in the vegetation is maintained along the whole chain. At the greater elevations the species which are identical with those of Europe become more frequent, and in the alpine regions many plants are found identical with species of the Arctic zone. On the Tibetan plateau, with the increased dryness, a Siberian type is established, with many true Siberian species and more genera; and some of the Siberian forms are further disseminated, even to the plains of Upper India. The total absence of a few of the more common forms of northern Europe and Asia should also be noticed, among which may be named *Tilia*, *Fagus*, *Arbutus*, *Erica*, *Azalea*, and *Cistaceæ*.

In the more humid regions of the east the mountains are almost everywhere covered with a dense forest which reaches up to 12,000 or 13,000 feet. Many tropical types here ascend to 7000 feet or more. To the west the upper limit of forest is somewhat lower, from 11,500 to 12,000 feet, and the tropical forms usually cease at 5000 feet.

In Sikim the mountains are covered with dense forest of tall umbrageous trees, commonly accompanied by a luxuriant growth of under shrubs, and adorned with climbing and epiphytal plants in wonderful profusion. In the tropical zone large figs abound, *Terminalia*, *Shorea* (sál), laurels, many *Leguminosæ*, *Bombax*, *Artocarpus*, bamboos, and several palms, among which species of *Calamus* are remarkable, climbing over the largest trees; and this is the western limit of *Cycas* and *Myristica* (nutmeg). Plantains ascend to 7000 feet. *Pandanus* and tree-ferns abound. Other ferns, *Scitamineæ*, orchids, and climbing *Aroidæ* are very numerous, the last-named profusely adorning the forests with their splendid dark-green foliage. Various oaks descend within a few hundred feet of the sea-level, increasing in numbers at greater altitudes, and becoming very frequent at 4000 feet, at which elevation also appear *Aucuba*, *Magnolia*, cherries, *Pyrus*, maple, alder, and birch, with many *Araliaceæ*, *Hollböllea*, *Skimmia*, *Daphne*, *Myrsine*, *Symplocos*, and *Rubus*. Rhododendrons begin at about 6000 feet and become abundant at 8000 feet, from 10,000 to 14,000 feet forming in many places the mass of the shrubby vegetation which extends some 2000 feet above the forest. Epiphytal orchids are extremely numerous between 6000 and 8000 feet. Of the Coniferæ, *Podocarpus* and *Pinus longifolia* alone descend to the tropical zone; *Abies Brunoniana* and *Smithiana* and the larch (a genus not seen in the western mountains) are found at 8000, and the yew and *Picea Webbiana* at 10,000 feet. *Pinus excelsa*, which occurs in Bhotán, is absent in the wetter climate of Sikim.

On the drier and higher mountains of the interior of the chain, the forests become more open, and are spread less uniformly over the hill-sides, a luxuriant herbaceous vegetation appears, and the number of shrubby *Leguminosæ*, such as *Desmodium* and *Indigofera*, increases, as well as *Ranunculaceæ*, *Rosaceæ*, *Umbelliferæ*, *Labiata*, *Gramineæ*, *Cyperaceæ*, and other European genera.

The alpine flora of Sikim closely resembles that of the western Himalaya, and so far as generic forms are concerned, that of the alpine regions of Europe and western Asia. The vegetation of the Tibetan region appears on rising above 14,000 feet, and its last representatives reach even to 18,000 feet.

Passing to the westward, and viewing the flora of Kumaon, which province holds a central position on the chain, on the 80th meridian, we find that the gradual decrease of moisture and increase of high summer heat are accompanied by a marked change of the vegetation. The

tropical forest is characterized by the trees of the hotter and drier parts of southern India, combined with a few of European type. Among them are *Moringa*, *Bombax*, *Butea*, *Anogeissus*, *Erythrina*, *Acacia*, *Bauhinia*, *Nauclera*, and *Ulmus integrifolia*. *Pinus longifolia* descends almost to the level of the plains. Among the more common shrubs are *Zizyphus*, *Adhatoda*, *Calotropis*, *Carissa*. Ferns are more rare, and the tree-ferns have disappeared. The species of palm are also reduced to two or three, and bamboos, though abundant, are confined to a few species.

The outer ranges of mountains are mainly covered with forests of *Pinus longifolia*, rhododendron, oak, and *Pieris*. At Naini-tal cypress is abundant. The shrubby vegetation comprises *Rosa*, *Rubus*, *Indigofera*, *Desmodium*, *Berberis*, *Bœhmeria*, *Viburnum*, *Clematis*, with an *Arundinaria*. Of herbaceous plants species of *Ranunculus*, *Potentilla*, *Geranium*, *Thalictrum*, *Primula*, *Gentiana*, and many other European forms are common. In the less exposed localities, on northern slopes and sheltered valleys, the European forms become more numerous, and we find species of alder, birch, ash, elm, maple, holly, hornbeam, *Pyrus*, &c. At greater elevations in the interior, besides the above are met *Corylus*, the common walnut, found wild throughout the range, horse chestnut, yew, also *Picea Webbiana*, *Pinus excelsa*, *Abies Smithiana*, *Cedrus Deodara* (which tree does not grow spontaneously east of Kumaon), and several junipers. The denser forests are commonly found on the northern faces of the higher ranges, or in the deeper valleys, between 8000 and 10,500 feet. The woods on the outer ranges from 3000 up to 7000 feet are more open, and consist mainly of evergreen trees.

The herbaceous vegetation does not differ greatly, generically, from that of the east, and many species of *Primulaceæ*, *Ranunculaceæ*, *Crucifera*, *Labiata*, and *Scrophulariaceæ* occur; balsams abound, also beautiful forms of *Campanulaceæ*, *Gentiana*, *Meconopsis*, *Saxifraga*, and many others.

Cultivation hardly extends above 7000 feet, except in the valleys behind the great snowy peaks, where a few fields of buckwheat and Tibetan barley are sown up to 11,000 or 12,000 feet. At the lower elevations rice, maize, and millets are common, wheat and barley at a somewhat higher level, and buckwheat and amaranth usually on the poorer lands, or those recently reclaimed from forest. Besides these, most of the ordinary vegetables of the plains are reared, and potatoes have been introduced in the neighbourhood of all the English stations.

As we pass to the west the species of rhododendron, oak, and *Magnolia* are much reduced in number as compared to the eastern region, and both the Malayan and Japanese forms are much less common. The herbaceous tropical and semi-tropical vegetation likewise by degrees disappears, the *Scitamineæ*, epiphytal and terrestrial *Orchidæ*, *Araceæ*, *Cyrtandraceæ*, and *Begoniæ* only occur in small numbers in Kumaon, and scarcely extend west of the Sutlej. In like manner several of the western forms suited to drier climates find their eastern limit in Kumaon. In Kashmir the plane and Lombardy poplar flourish, though hardly seen further east, the cherry is cultivated in orchards, and the vegetation presents an eminently European cast. The alpine flora is slower in changing its character as we pass from east to west, but in Kashmir the vegetation of the higher mountains hardly differs from that of the mountains of Afghanistan, Persia, and Siberia, even in species.

The flora of western Tibet is essentially European in its character. The juniper and poplar are the only trees that are seen, excepting fruit-trees, which include apricot, pear, and grape. The shrubby plants include small forms of willow, elm, *Lonicera*; rose, *Myricaria*, *Ephedra*, and

Hippophae. The ordinary firewood of the more elevated tracts is supplied by bushes of *Caragana*, the furze of travellers, and dwarf *Lonicera* and willow. Species of *Astragalus*, *Urtica*, *Allium*, small *Cruciferae* and saxifrages, *Saussurea*, and *Rheum* are common. *Artemisia* and many salt-plants, with *Glaux maritima* and *Triglochin*, are found, especially on the borders of the salt lakes. Mosses and ferns are very rare. Many European grasses and *Carices* occur in the pastures. The herbaceous vegetation ascends freely to 16,000 feet, and isolated plants may be found as high as 19,000 feet; but excepting in the close neighbourhood of small streams the growth is very scanty, and not one-twentieth of the surface is commonly clothed with vegetation. Barley is cultivated up to 15,000 feet, wheat, millet, and rape, with buckwheat, being common up to 12,000 feet. Apples and apricots grow up to 11,000 and 12,000 feet, and grapes to 9000 feet.

The total number of flowering plants inhabiting the range amounts probably to 5000 or 6000 species, among which may be reckoned several hundred common English plants chiefly from the temperate and alpine regions; and the characteristic of the flora as a whole is that it contains a general and tolerably complete illustration of almost all the chief natural families of all parts of the world, and has comparatively few distinctive features of its own.

The timber trees of the Himalaya are very numerous, but few of them are known to be of much value, and the difficulties of transport are so great as to render their removal to a distance in many cases impracticable. The "Sál" is one of the most valuable of the trees; with the "Toon" and "Siseco," it grows in the outer ranges most accessible from the plains. The "Deodar" is also much used, but the other pines produce timber that is not durable. Bamboos grow everywhere along the outer ranges, and ratans to the eastward, and are largely exported for use in the plains of India. Other vegetable products of economical value, excluding the ordinary cereals and esculent plants, are not numerous; and the primitive condition of the people and the difficulties and expense of carriage are so great as to render the trade in such articles very insignificant.

Though one species of coffee is indigenous in the hotter Himalayan forests, the climate does not appear suitable for the growth of the plant which supplies the coffee of commerce. The cultivation of tea, however, is now carried on successfully on a large scale, both in the east and west of the mountains, and has already become an important item of the export trade of India. In the western Himalaya the cultivated variety of the tea plant of China has been introduced, and succeeds well; on the east the indigenous tea of Assam, which is not specifically different, and is perhaps the original parent of the Chinese variety, is now almost everywhere preferred. The produce of the Chinese variety in the hot and wet climate of the eastern Himalaya, Assam, and eastern Bengal is neither so abundant nor so highly flavoured as that of the indigenous plant, and therefore not so commercially valuable.

The cultivation of the cinchona, several species of which have been introduced from South America and naturalized in the Sikim Himalaya, is still in its infancy, but promises to yield at a comparatively small cost an ample supply of the precious febrifuge that is extracted from its bark. At present the manufacture is almost wholly in the hands of the Government, and the drug prepared is all disposed of in India. The progress of cinchona cultivation on the Nilgherries is not less promising than on the Himalaya.

The general distribution of animal life on these mountains is manifestly determined by much the same conditions that have controlled the vegetation. The connexion with Europe on the north-west, with China on the north-east, with Africa on the south-west, and with the Malayan region on the

south-east is manifest; and the greater or less prevalence of the European and Eastern forms varies according to more western or eastern position on the chain. So far as is known these remarks will apply to the extinct as well as to the existing fauna. The Palæozoic forms found in the Himalaya are very close to those of Europe, and in some cases identical. The Triassic fossils are still more closely allied, more than a third of the species being identical. Among the Jurassic Mollusca, also, are many species that are common in Europe. The Siwalik fossils contain 84 species of mammals of 45 genera, the whole bearing a marked resemblance to the Miocene fauna of Europe, but containing a larger number of genera still existing, especially of ruminants, and as before stated now held to be of Pliocene age.

The fauna of the Tibetan Himalaya is essentially European, or rather that of the northern half of the old continent, which region has by zoologists been termed Palæarctic. Among the characteristic animals may be named the yák, from which is reared a cross breed with the ordinary horned cattle of India locally called "zobu," many wild sheep, and two antelopes, as well as the musk-deer; several hares and some burrowing animals, including pikas (*Lagomys*) and two or three species of marmot; certain arctic forms of carnivora—fox, wolf, lynx, ounce, marten, and ermine; also wild asses. Among birds are found bustard and species of sand-grouse and partridge; water-fowl in great variety, which breed on the lakes in summer and migrate to the plains of India in winter; the raven, hawks, eagles and owls, a magpie, and two kinds of chough; and many smaller birds of the passerine order, amongst which are several finches. Reptiles, as might be anticipated, are far from numerous, but a few lizards are found, belonging for the most part to types, such as *Phrynocephalus*, characteristic of the Central-Asiatic area. The fishes from the head waters of the Indus also belong, for the most part, to Central-Asiatic types, with a small admixture of purely Himalayan forms. Amongst the former are several peculiar small-scaled carps, belonging to the genus *Schizothorax* and its allies.

The ranges of the Himalaya, from the border of Tibet of Himalaya to the plains, form a zoological region which is one of the richest of the world, particularly in respect to birds, to which the forest-clad mountains offer almost every range of temperature.

Only two or three forms of monkey enter the mountains, the langúr, a species of *Semnopithecus*, ranging up to 8000 or 9000 feet. No lemurs occur, although a species is found in Assam, and another in southern India. Bats are numerous, but the species are for the most part not peculiar to the area; several European forms are found at the higher elevations. Moles, which are unknown in the Indian peninsula, abound in the forest regions of the eastern Himalayas at a moderate altitude, and shrews of several species are found almost everywhere; amongst them are two very remarkable forms of water-shrew, one of which, however, *Nectogale*, recently discovered, is probably Tibetan rather than Himalayan. Bears are common, and so are a marten, several weasels and otters, and cats of various kinds and sizes, from the little spotted *Felis bengalensis*, smaller than a domestic cat, to animals like the clouded leopard rivalling a leopard in size. Leopards are common, and the tiger wanders to a considerable elevation, but can hardly be considered a permanent inhabitant, except in the lower valleys. Civets, the mungoose (*Ichneumon*), and tree-cats (*Paradoxurus*) are only found at the smaller elevations. Wild dogs (*Cuon*) are common, but neither foxes nor wolves occur in the forest area. Besides these carnivora some very peculiar forms are found, the most remarkable of which is *Alurus*, sometimes called the cat-bear, a type

Number of species and character of families.

Zoology. General characters.

peculiar to the Himalaya. Two other genera, *Helictis*, an aberrant badger, and *Prionodon*, an aberrant civet, are representatives of Malayan types. Amongst the rodents squirrels abound, and the so-called flying squirrels with a membranous expansion or parachute between their fore and hind legs are represented by several species. Rats and mice swarm, both kinds and individuals being numerous, but few present much peculiarity, a bamboo rat (*Rhizomys*) from the base of the eastern Himalaya being perhaps most worthy of notice. Two or three species of vole (*Arvicola*) have been detected, and porcupines are common. The elephant is found in the outer forests as far as the Jumna, and the rhinoceros as far as the Sarda; the spread of both of these animals as far as the Indus and into the plains of India, far beyond their present limits, is authenticated by historical records; they have probably retreated before the advance of cultivation and fire-arms. Wild pigs are common in the lower ranges, and one peculiar genus of pigmy-hog (*Porculia*) of very small size inhabits the forests at the base of the mountains in Nepál and Sikim. Deer of several kinds are met with, but do not ascend very high on the hill sides, and belong exclusively to Indian forms. The musk deer keeps to the greater elevations. The chevrotains of India and the Malay countries are unrepresented. The gaur or wild ox is found at the base of the hills. Three very characteristic ruminants, having some affinities with goats, inhabit the Himalaya; these are the "serraw," "goral," and "táhr," the last-named ranging to rather high elevations. Lastly, the pangolin or manis is represented by two species in the eastern Himalaya. A dolphin living on the Gauges ascends that river and its affluents to their issue from the mountains.

Birds. Almost all the orders of birds are well represented, and the marvellous variety of forms found in the eastern Himalaya is only rivalled in Central and South America. Eagles, vultures, and other birds of prey are seen soaring high over the highest of the forest-clad ranges. Owls are numerous, and a small species, *Glaucidium*, is conspicuous, breaking the stillness of the night by its monotonous though musical cry of two notes. Several kinds of swifts and nightjars are found, and gorgeously-coloured trogons, bee-eaters, rollers, and beautiful kingfishers and barbets are common. Several large hornbills inhabit the highest trees in the forest. The parrots are restricted to parakeets, of which there are several species, and a single small lory. The number of woodpeckers is very great, and the variety of plumage remarkable, and the voice of the cuckoo, of which there are numerous species, resounds in the spring as in Europe. It is impossible to do more than indicate some of the chief passerine birds; their number is immense. Amongst them the sun-birds resemble in appearance and almost rival in beauty the humming-birds of the New Continent. Creepers, nuthatches, shrikes, and their allied forms, flycatchers and swallows, thrushes, dippers and babblers (about fifty species), bulbuls and orioles, peculiar types of redstart, various sylvias, wrens, tits, crows, jays, and magpies, weaver-birds, avadavats, sparrows, crossbills, and many finches, including the exquisitely coloured rose-finches, may also be mentioned. The pigeons are represented by several wood-pigeons, doves, and green pigeons. The gallinaceous birds include the peacock, which everywhere adorns the forest bordering on the plains, jungle fowl, and several pheasants; partridges, of which the chukor may be named as most abundant; and snow-pheasants and partridges, found only at the greatest elevations. Waders and waterfowl are far less abundant, and those occurring are nearly all migratory forms which visit the peninsula of India,—the only important exception being two kinds of solitary snipe, and the red-billed aurlew.

Of the reptiles found in these mountains many are ^{Reptiles} peculiar. Some of the snakes of India are to be seen in the hotter regions, including the python and some of the venomous species, the cobra being found as high up as 8000 or 9000 feet, though not common. Lizards are numerous, and as well as frogs are found at all elevations from the plains to the upper Himalayan valleys, and even extend to Tibet.

The fishes found in the rivers of the Himalaya show the same general connexion with the three neighbouring regions, the Palæartic, the African, and the Malayan. Of the principal families, the *Acanthopterygii*, which are abundant in the hotter parts of India, hardly enter the mountains, two genera only being found, of which one is the peculiar amphibious genus *Ophiocephalus*. None of these fishes are found in Tibet. The *Siluridæ* or scaleless fishes, and the *Cyprinidæ*, or carp and loach, form the bulk of the mountain fish, and the genera and species appear to be organized for a mountain-torrent life, being almost all furnished with suckers to enable them to maintain their positions in the rapid streams which they inhabit. A few *Siluridæ* have been found in Tibet, but the carps constitute the larger part of the species. Many of the Himalayan forms are Indian fish which appear to go up to the higher streams to deposit their ova, and the Tibetan species as a rule are confined to the rivers on the table-land or to the streams at the greatest elevations, the characteristics of which are Tibetan rather than Himalayan. The *Salmonidæ* are entirely absent from the waters of the Himalaya proper, of Tibet, and of Turkistan east of the Terek-tág. On crossing the watershed that leads from the streams flowing into the Indus to those falling into the Oxus, a trout is reported to have been found, though it is said not to live in the Jaxartes or its affluents.

No such general or connected account of the Mollusca, ^{Other orders of animal kingdom.} insects, or other lower forms of life, of these mountains exists as will admit of anything but very vague statements regarding them. It is, however, understood that the same relations with the neighbouring European, Asiatic, and African regions are found to exist as have been noticed as characterizing the other forms of life.

Of the land Mollusca, one-half appear to belong to the ^{Mol-} genera *Helix* and *Bulinus*, and about one-third to the ^{lusca.} family of *Cyclostomidæ*; the species appear to be for the most part very local, and of about 120 species in all, only about one-tenth are recorded as being found in Tibet or the highest Himalayan valleys.

The Himalayan butterflies are very numerous and brilliant, ^{Insects} for the most part belonging to groups that extend both into the Malayan and European regions, while African forms also appear. There are large and gorgeous species of *Papilio*, *Nymphalidæ*, *Morphidæ*, and *Danaidæ*, and the more favoured localities are described as being only second to South America in the display of this form of beauty and variety in insect life. Moths, also, of strange forms and of great size are common. The cicada's song resounds among the woods in the autumn; flights of locusts frequently appear after the summer, and they are met far within the mountains, carried by the prevailing winds even among the glaciers and eternal snows. Ants, bees, and wasps of many species, and flies and gnats in great variety of form, and possessed of equal variety of powers of annoyance, abound, particularly during the summer rainy season, and at all elevations.

Apart from the connexion which subsists between the Himalaya and the earliest developments of the Hindu religion, there is little in these mountains that is of interest as throwing light on the earlier history of our race. The mythical geography of the Hindus represents the peak of Kailás, the snowy mountain north of the Tibetan lake

of its visionary kingdoms are spread out. The sanctity of the Himalaya, in Hindu mythology, is known to all, and thousands of pilgrims from all parts of India still continue to seek salvation in the holy waters of the Ganges, and at its sacred sources in the snowy Himalaya. "He who thinks on Himáchal," says the Mánas-khanda, one of the Puránas or holy books of the Hindus, "though he should not behold him, is greater than he who performs all worship at Káshi (Benares). In a hundred ages of the gods I could not tell of the glories of Himáchal. As the dew is dried up by the morning sun, so are the sins of mankind by the sight of Himáchal." And to those who have performed such a pilgrimage the wondrous snow-clad peaks of the Himalaya, though seen through the atmosphere of the 19th century, seem still to be surrounded with the same halo of glory as of old.

The Ganges, which issues from the mountains at Hardwár, is fed by two principal tributaries which unite about 40 miles higher up, the Alaknanda, far the larger, and the Bhághirati, the more sacred. The source of the last-named river is in the glacier above the temple at Gangotri, which lies to the north of a great cluster of snowy peaks, on the south of which is found the temple of Kedarnáth, and on the east that of Badarináth. Large glaciers exist near both of these temples, that near Kedarnáth feeding the Mandákni, and that near Badarináth feeding the Vishnuganga, which river gives the main supply of water to the Alaknanda. Both the valley above Gangotri and that above Badarináth lead to Tibet, passing through a region of snowy peaks of first-class magnitude. To the west of Gangotri and the Bhaghirati lies the hardly less sacred source of the Jumna and the temples of Jamnotri.

The temple at Badarináth, on the Vishnuganga, as the latter name suggests, is dedicated to Vishnu, and is served by priests of the Vaishnava sect, presided over by a "Ráwal" or abbot, who is invariably a Brahman from South India. The temple at Kedarnáth is dedicated to Shiva, symbolized by the Lingam, and is more especially venerated by the Saiva sect; and the chief-priest here, too, is a Brahman from Malabar in the same part of India. The origin of this connexion of the holy places in the Himalaya with southern India is very obscure; possibly, however, it dates back to the 8th or 9th century, to the time of Sankara Acháraya, a native of Malabar, the chief expositor of the Saiva doctrines, who is said to have died at Kedarnáth. That the Himalaya and the sources of the Ganges, however, were regarded as holy, and had become places of pilgrimage for Hindus long before this event, or before the development of the two sects that have been here specially named, there can be no reasonable doubt; but how or when the Aryan races of India first developed for themselves a system of mythology so intimately bound up with these mountains must ever remain a subject of mere speculation.

Remains of Buddhist monasteries and temples on a great scale, the majority of which are believed from inscriptions found on them to date back to about the commencement of the Christian era, are met with along the foot of the western end of the Himalaya, in the Yusafzai country bordering on the Indus, and similar ruins are seen as far west as Jellalabad in Afghanistan. Some of the buildings are doubtless of much greater age, and may go back to the earliest days of Buddhism, about six centuries before our era; and the discovery in this locality of what is probably a contemporaneous copy of Asoka's well-known inscription, cut into the face of a great rock, testifies to the development of a great centre of Buddhism in his days, that is, about 250 B.C. Among these ruins are found fragments

of sculpture bearing the impress of the Greek art introduced by the successors of Alexander; and other relics of the Greco-Scythic kings, in the form of numerous coins, have been obtained from the same quarter. The exact point at which Alexander entered India is still a subject of discussion among antiquaries, but it probably was on the line following the skirt of the north-west Himalaya along which the road now runs, and which is known to have been the chief line of traffic for centuries. How the influence of Greek architecture was carried forward both in time and place is illustrated by the curious temple of the sun, or "Marttand," in the valley of Kashmir, the date of which is about 400 A.D.

It would be a task, certainly fruitless, and probably impossible, to endeavour to estimate aright the conflicting claims to admiration of the scenery of the Himalaya and other great mountain ranges. If some elements of the picturesque be better found elsewhere, and if the softer features of hill, valley, and lake be absent, yet nowhere can the Himalaya be surpassed in the magnificence and variety of its forests, or in the wealth and beauty of its alpine flora, which offer to the traveller ever-changing and ever-renewed pictures, combining the charm of former memories with fresh conceptions of the wonderful never-failing profusion of nature; and to the student of natural phenomena of every description surely no grander field will ever be open than that presented by these mountains.

In many circumstances mere magnitude may not be effectual in adding to the apparent grandeur or sublimity of mountain scenery, for everywhere the features nearest to the eye, though absolutely smaller, may cut off from view those of far greater importance which are further removed. And this is often conspicuously true in the valleys of the Himalaya. But the extraordinary scale on which every part of the mountains is developed, the actual vast dimensions of the main features, the apparently endless succession of range after range, of ascent and descent, of valley and mountain top, of river, torrent, and brook, of precipitous rock and grassy slope, of forest and cultivated land, cannot fail to produce impressions of wonder, which are not likely to be equalled and certainly will not be exceeded on any other chain. Upon these mountains alone, of all on the earth, can the traveller, as he climbs their slopes, obtain at a glance a range of vision extending 5 miles in vertical height, from 2000 or 3000 feet to 29,000 feet above the sea, and see spread out before him a compendium of the entire vegetation of the globe from the tropics to the poles. Here may the eye as it sweeps along the horizon embrace a line of snow-clad mountains, such as exist in no other part of the world, stretching over one-third of the entire circle, at a distance of 40 or 50 miles, their peaks towering over a sea of intervening ranges piled one behind another, whose extent on either hand is lost in the remote distance, and of which the nearest rises from a gulf far down beneath the spectator's feet, where may be seen the silver line that marks a river's course, or crimson fields of amaranth and the dwellings of man. Sole representative of animal life, some great eagle floats high overhead in the pure dark-blue sky, or, unused to man, fearlessly sweeps down within a few yards to gaze at the stranger who intrudes among these solitudes of nature. As the sun sinks the cold grey shadow of the summit where we stand is thrown forward, slowly stealing over the distant hills, and, veiling their glowing purples as it goes, carries the night up to the feet of the great snowy peaks, which still rise radiant in rosy light above the now darkening world. From east to west in succession the splendour fades away from one point after another: and the vast shadow of the

Grandeur of the views it affords.

earth is rapidly drawn across the whole vault of heaven. One more departing day is added to the countless series which has silently witnessed the death-like change that passes over the eternal snows as they are left raising their cold pale fronts against the now leaden sky; till slowly

with the deepening night the world of mountains rises again, as it were to a new life, under the changed light of the thousand stars which stud the firmament and shine with a brilliancy nukuown except in the clear rarefied air of these sublime heights. (R. S.)

HIMERA, a city on the north coast of Sicily. It was founded in 648 B.C. by the Chalcidian inhabitants of Zancle, but with them were many Syracusan exiles who gave to the language of the city a Doric character. Early in the 5th century the tyrant Terillus, being expelled by Theron of Agrigentum, invoked the aid of the Carthaginians. They gladly availed themselves of the pretext, but their general Hamilcar was defeated at Himera by the Greeks under Gelon of Syracuse (480 B.C.). Thrasydæus, son of Theron, brought a large body of Doric immigrants to the city in 476; but was not long after expelled by Hiero. It seems to have enjoyed great prosperity during the rest of the 5th century. In 415 it refused to admit the Athenian fleet, and was a zealous ally of Syracuse. In 408 the Carthaginians sent another great army under Hannibal, grandson of Hamilcar, who razed the city to the ground. A new city called *Thermæ Himerenses* was founded in 407 close to the former site. This name was derived from the famous hot springs, in which Hercules was said to have bathed. The new city was in Carthaginian hands till it was annexed by the Romans in the Second Punic War. It was treated with peculiar favour by them, and was left a free city under its own laws. In the time of Cicero it was a flourishing town, though not very large. Under Augustus it became a "colonia." We hear little of it from that time, though the site was never deserted, and the town still exists under the name of Termini. Ergotetes, an Olympian victor celebrated by Pindar (*Ol.* xii.), was a citizen of Himera. Stesichorus the poet was a native of the city; and his statue was preserved at *Thermæ* in the time of Cicero. *Agathocles* also was a native of *Thermæ*.

HIMMEL, **FREDERICK HENRY** (1765–1814), a German composer of mark, was born November 20, 1765, at Treuenbrietzen in Brandenburg, Prussia, and originally studied theology at Halle. During a temporary stay at Potsdam he had an opportunity of showing his self-acquired skill as a pianist before King Frederick William II., who thereupon made him a yearly allowance in order to enable him to complete his musical studies. This he did under Naumann, a German composer of the Italian school, and the style of that school Himmel himself adopted in his serious operas. The first of these, a pastoral opera *Il Primo Navigatore*, was produced at Venice in 1794 with great success. After his return to Berlin in 1795 Himmel became court chapel master to the king of Prussia, and in that capacity wrote a great deal of official music, such as cantatas, a coronation *Te Deum*, and the like, now justly forgotten. The same fate is shared by his Italian operas, successively composed for Stockholm, St Petersburg, and Berlin, and all received with great applause in their day. Infinitely more important than these is an operetta to German words called *Fanchon*, the popularity of which has seldom been surpassed. Although antiquated it still remains an admirable specimen of the primitive form of the musical drama known in Germany as the "Singspiel." Himmel's gift of writing genuine simple melody, to which the operetta owed its success, is also observable in his songs, amongst which one called "To Alexis" is the best. It may be found in the first volume of the *Musical Library*. Himmel died at Berlin, June 8, 1814.

HINCKLEY, a market-town of England, county of Leicester, is situated 13 miles S. W. of Leicester, on a branch

line between that town and Nuneaton, which connects the London and North-Western and the Midland railways. The principal buildings are the church of St Mary, a Gothic structure lately restored, with tower and spire 120 feet high; the town-hall; the priestshouse and Roman Catholic academy named St Peter's Priory; and the union poorhouse, erected in 1838, with accommodation for 400 inmates. There are a grammar school, a national school, and board schools. Hinckley is the centre of the stocking-weaving district, and its speciality is circular hose. It also possesses breweries, brick and tile works, and lime works. There are several mineral springs in the neighbourhood, and at one of these baths have been erected. The population in 1871 was 6902.

Hinckley was created a barony soon after the Conquest, when it was held by Hugh de Grentismenil, who erected a castle, the ditch of which is still traceable, and also founded a priory of Benedictine monks. Originally the town had the privileges of a borough, but these were annulled by Edward IV. Mention is made of "Hinckley Fair" in the second part of *Henry IV.*, act v. sc. 1.

HINCMAR (c. 806–882), archbishop of Rheims from 845 to 882, a prominent figure in most of the theological and ecclesiastical struggles of his day, and perhaps the most vigorous and influential prelate France has ever produced, belonged to a noble West Frankish family, and was born about the year 806. Other forms of the name are Ingumar, Ingmar, and Igmarr. His early education was received at the abbey of St Denis under Hilduin (the author of *Areopagitica*), whom he followed to Corvey, Westphalia, when banished by Louis the Pious in 830 for having joined the party of Lothair. Returning about two years afterwards along with his superior to St Denis, of which he had become a canon, he resided partly there and partly at court, where he rapidly rose high in the royal favour. He was with Louis at the "Field of Falsehood" (*Campus mendacii*) in Alsace, and was one of the few who remained faithful when the majority of the prelates and nobles went over to the other side. After the death of Louis (840), he equally gained the confidence of Charles the Bald, through whose influence, after he had successively held the abbacies of St Mary's, of Compiègne, and of St Germer, he was in 845 elected to succeed the deposed Ebo or Ebo in the archiepiscopal see of Rheims. Having exacted from Charles a full restitution of all the church property which had belonged to the diocese, and a further promise that it should never again be alienated, he at once entered on the duties of his office, and took a leading part in the council of Meaux (C. Meldense), the reforming decrees of which so strongly roused the opposition of the king. Some attempt having been made to revive the claims of Ebo, Hincmar's title to the archbishopric was confirmed by a synod of French bishops at Paris, and ultimately settled by Leo IV.'s transmission of the pallium in 847. Apart from the ordinary affairs of his diocese, which included the completion and adornment of the cathedral begun by his predecessor, he now became deeply involved in the discussions which arose out of the predestinarianism of Gottschalk (see **GOTTSCHALK**), whom Hrabanus Maurus at the synod of Mainz (848) had caused to be relegated to Hincmar as his metropolitan. At a synod held at Quierzy on the Oise (Carisiacum), in the diocese of Soissons, in 849, Hincmar had united with Wenilo of Sens and other prelates in condemning the refractory monk to degradation, scourging,

and imprisonment; but in a short refutation of the "predestinarian heresy," which he himself shortly afterwards wrote and circulated, he so failed to do justice to the orthodox faith as to elicit the censure of Ratramnus of Corvey, who was afterwards supported by Prudentius of Troyes, Lupus of Ferrières, and a large Augustinian party (850). Hincmar now summoned the dialectic skill of John Scotus Erigena to his aid, and the controversy became general. Another synod held at Quierzy in 853 passed the four "Capitula Carisiaca," which in substance taught that there is but one divine predestination; that free will, lost by the fall, is restored by the preventing and assisting grace of Christ; that God wills generally that all men should be saved; and that the blood of Christ was shed for all. These were answered by the six canons of the (Lotharingian) synod of Valence, which elicited from Hincmar, two years afterwards, the *De Prædestinatione Dei et Libero Arbitrio Libri tres*, of which all that is now extant is the prefatory letter to the king. By the synod of Langres (S. Lingonensis, 859), however, the articles of Valence were confirmed,—a decision which was afterwards supported by the general synod held at Savona or Savonnières, otherwise known as the Concilium Tullense (859). Hincmar now published the *Posterior de Prædestinatione Dei et Libero Arbitrio Dissertatio*, but without influencing the voice of the church; nor was he more successful in his controversy with Gottschalk on the Trinity, his *Collectio ex Sanctis Scripturis et Orthodoxorum Dictis* against the phrase "Trina Deitas" having been totally disregarded; he had, however, the satisfaction of preventing the release of Gottschalk, who died in prison in 868. While these speculative controversies were doubtfully raging, Hincmar found scope for his greater practical talent in the events which followed the death of the emperor Lothair in 855, and which chiefly resulted in the strengthening of clerical ascendancy. Having saved Charles from the hands of his own nobles and of the Germans, the great metropolitan was in a position at last to say, "If kings rule after God's will, they are subject to none; if they be great sinners then is their judgment in the hands of the bishops." In 860 began the divorce suit in which the interests of Thietberga, the oppressed queen of Lothair II., were involved; and here, undoubtedly, the whole weight of Hincmar's influence was thrown into the scale of morality and right. His contribution to the discussion is still extant in the treatise *De Divortio Lotarii et Teutbergæ Reginae* (860). While this controversy still remained unsettled, Hincmar became involved in a struggle with the pope (Nicholas I.), which is of very considerable historical importance from the part which was played in it by the newly introduced "Isidorian" decretals, and from the effect which it had in limiting the rights of metropolitans. Rothad, bishop of Soissons, having been deposed for acts of insubordination and violations of duty at a synod of Soissons presided over by Hincmar in 863, had appealed to Rome; the appeal had been sustained; and ultimately in 865 orders were given that the judgment of Hincmar should be reversed, and that his suffragan should be restored to his office. The decision, which, though not without murmuring and contentions, was acquiesced in by Hincmar, was an important step in the development of the hierarchical monarchy of Rome. Hincmar was somewhat more successful when he found himself in opposition to the successor of Nicholas, Adrian II. This pope, who highly disapproved of the action of the archbishop in crowning Charles as the successor of King Lothair of Lorraine in 869, had fulminated threats of excommunication against all who had been concerned in that action; Hincmar replied that the Roman see had no right to interfere in such a matter, and that the impending ban would have no validity; and the actual result was that, notwithstanding

alike the protest of the emperor and the prohibition of the pope, Charles the Bald and Louis the German quietly divided the dominions of their nephew. Again, when Hincmar of Laon, his nephew and suffragan, had defied his authority and appealed to the pope, a long controversy resulted in the appellant's being imprisoned, degraded, and sentenced to the loss of his eyes (871). Of the remaining years of Hincmar's life few incidents are recorded; in 882 he was compelled by Norman invasion to transfer his see to Epernay, where in the same year he died.

The works of Hincmar, which include, besides these already mentioned, a variety of capitula and other occasional pieces, were first edited by Simond in 2 vols. fol. (1645). They are reprinted in Migne's *Cursus Patr. Comp.* The *Annales Bertiniani* from 861 to 882 are also by Hincmar. See Gess, *Merkwürdigkeiten aus dem Leben und Schriften Hincmars* (1806); Prichard, *The Life and Times of Hincmar* (1849); and Noorden, *Hincmar, Erzbischof von Rheims* (1863).

HINDLEY, a manufacturing town of Lancashire, is situated on the Lancashire and Yorkshire railway, 3 miles south-east of Wigan. Cotton-spinning and the manufacture of cotton goods are the principal industries, and there are extensive coal-mines in the neighbourhood. Hindley possesses a grammar school, and among its places of worship may be mentioned the old parish church, and St Peter's church, erected in 1864 in the First Pointed style. In the time of the Puritan revolution Hindley church was entered by the Cavaliers, who played at cards in the pews, pulled down the pulpit, and tore the bible in pieces. The population in 1871 was 10,627.

HINDOL, one of the tributary states of Orissa, India, situated between 20° 29' 30" and 20° 49' 30" N. lat., and between 85° 8' 35" and 85° 31' 15" E. long. It is surrounded on all sides by native states, being bounded on the N. and E. by Dhenkanal, on the S. by Barambá and Narsinhpur, and on the W. by Angul. Area, 312 square miles; population (1872), 28,025 (Hindus, 23,345; Mahometans, 122; and "others," 4558). The Cuttack and Sambalpur highroad runs through the state. Only five villages contain upwards of 100 houses. Hindol consisted originally of three or four petty states, completely buried in jungle, and ruled by separate chiefs, till two Marhattá brothers, belonging to the family of the Kimidi Rájá in Madras, drove them out, and formed their territories into one principality. The present chief maintains a military force of 83 men, and a police force 133 strong. His estimated annual revenue is returned at £2082; tribute, £55.

HINDÚ KÚSH is a title applied to the line of alpine watershed stretching W.S.W. from the southern margin of Pamir, the Caucasus of Alexander's historians, which divides Afghanistan in a general sense from Afghan Turkestan, and the basin of the Cabul river from the basin of the Oxus. Looking towards the heart of a map of Asia, the eye is caught by that remarkable point where the great highland seems clenched as it were to a knot, whence expand in different directions (1) to east and south-east the great Tibetan plateau, (2) to north that of Pamir, and (3) to west that of Khorasan and Persia. Between the diverging masses run up the great basins of the Indus, the Yarkand river, and the Oxus. Some dim memory of these great features perhaps, transformed and transplanted further east, appears in the cosmography of the Puranas, in which the mythical Ganges falling on Mount Meru divides into four great rivers flowing to the cardinal points.

This is the first impression. But, imperfectly as we yet know the mountain structure, the more we learn the more evanescent becomes this idea of triplicity as typifying the true skeleton. This node is in fact the place of contact or intersection of two great elevations:—(1) of the Himalaya,

of which the axial lines approach in a direction from S.E. to N.W.; and (2) of the Thian-Shan and allied ranges, of which the axial lines run from E.N.E. to W.S.W. The parallelism of Hindú Kúsh seems to attach it to the latter system.

The definition of geographical features must often be in part arbitrary, but that of Hindú Kúsh fairly coincides with natural limits. On the east we take it as commencing at the Baroghil Pass, leading from the high valley of Little Pamir south into the valley of Káshgár or Chitrál. Just east of this is a cluster of peaks of great altitude, but their alignment attaches them to the great Gilgit range of the Himalaya (Múztagh of some maps, *Dapsang* of Richthofen). On the west we regard Hindú Kúsh as including and terminating at the Hajjigak Passes, those most commonly used between Cabul and Turkestan. West of this the range continues as a watershed of considerable altitude, but with a partial change of direction and loss of true alpine character. In maps this prolongation is styled Koh-i-Baba. Properly Koh-i-Baba is the name of a conspicuous three-peaked mountain rising over the Hajjigak Pass, to a height of at least 16,500 feet, which we regard as the terminal prominence of Hindú Kúsh, though it is in truth also isolated from the higher summits to the eastward, which especially claim that name, by a considerable interval of tamer mountain, rounded and naked.

The total length of Hindú Kúsh as thus defined is 365 miles. Towards the eastern extremity the watershed perhaps emerges little from the table-land, for the Baroghil Pass is of singularly easy acclivity on both sides, and no prominent summits adjoin it on the west. But for the rest of its extent the mountain tract of Hindú Kúsh realizes the popular idea of an alpine chain, *i.e.*, of an unpierced mountain barrier whose passes are never far below the line of perpetual snow, and whose highest peaks are never very far from the watershed.

The general altitude of the "cols" or passes runs from 12,000 to 13,000 feet. We give those that have been calculated (besides which some 20 or 22 are known more vaguely), beginning from the east:—

	Long	Feet.
1. Baroghil Pass	73°26'	12,000
2. Nuksán „	71°37'	17,000
3. Dora „	71°24'	16,000–16,500
4. Khawak „	69°39'	13,200
5. Sar-ulang „	68°47'	12,000
6. Kúshán „	68°40'	15,000
7. Irák „	67°52'	12,900
8. Kálú „ (on Hajjigak Road) 67°45'		12,480

The three highest (2, 3, 6) do not rest upon any observations of barometer or boiling point, but on other and looser data. Of the height of the peaks we have nothing definite. Captain Burslem, who ascended Koh-i-Baba with Lieutenant Sturt in 1840, speaks of seeing the lofty peaks to the eastward "many thousand feet" above, and Burnes uses similar language. The great peak near the Kúshán Pass, sometimes specially called Hindú Kúsh, which is seen at once from Cabul on the south and from Kunduz on the north, is probably not less than 20,000 feet high. Much further east the estimated heights of passes 2 and 3 indicate probable summits of as great altitude. A great mountain due north of Chitrál, called Tirich Mir, and said to be visible from a great part of Kafiristán and from Zebák in Badakhshan, is estimated by Major Biddulph, who alone has seen it, at the enormous height of 27,000 feet, but General Walker reduces this to 23,000 with a (?).

Apart from this exceptional peak we shall form a just conception of the calibre of Hindú Kúsh among the ranges of the world if we class it with the French and Swiss Alps in extent and mass, but with greater average altitude. We have only one report of a glacier, *viz.*, on the Nuksán Pass, No. 2 in the list of heights above.

The idea of a distinct southern range running parallel to Hindú Kúsh, north of the Cabul river, which Wood calls "the Himalaya," is founded on misconception. But peaks have been measured on the spurs which run south on both sides of the Kunar river. They rise to near 19,000 feet on the left bank, east of Chitrál, descending to 11,800 near the Afghan boundary. In Kafiristán there are peaks on these spurs of 16,600 and 16,800 feet, and even within 25 miles of the Cabul river are some as high as 14,000 feet.

On the south side of Hindú Kúsh the earliest sources of the Helmand are in the gorges up which the Koh-i-Baba passes mount. All the rest of the range drains on that side to the Cabul river, and so to the Indus. On the north all the drainage reaches the Oxus.

Both hydrographic features and the limits of our knowledge conveniently divide the Hindú Kúsh into three sections.

(1.) Beginning from the east, in the first section, drainage southward is into the Chitrál valley, and forms the great, perhaps greatest, contributory to the Cabul river, known as the Kunar or Beilam (probably *Choaspes* and *Malamanthus* of the ancients). The highest part of this basin is known as Chitrál *Balá* (upper), and is politically united to Yasin in the Gilgit basin (see GILGIT). It consists of two or three confluent valleys, some of them thick with villages, whose continuous cultivation, supported by copious springs, extends far up the hill-sides. Mastúj, the chief place, stands 7500 feet high, in 36° 10' N. lat. Twenty miles farther down is the boundary of Lower Chitrál or Káshgár. This forms a state of which the chief or king (he is styled "Bádsáh") resides at Chitrál town (height 5200 feet, 35° 53' N. lat.). The people are Moslem, apparently a converted section of the neighbouring Kafirs, and speaking a kindred dialect of Sanskritic affinity. Fruit is good, including fine grapes, and the wine was once famous. Chitrál is the Bolor of Chinese geography, the misplacement of which so long perplexed and vitiated the geography of the Pamir highlands. The name *Balaur* mediævally covered a larger tract, probably the whole of the then pagan country from Khawak Pass to the Indus. Below Chitrál the valley narrows, and is shut in by Kafir villages in nominal subjection to the small state of Asmar (35° 4' N. lat.). Afghan territory begins at Maraora, 20 miles further down. On the north of this section most part of the drainage flows directly into the Little Pamir stream of the Oxus, or into the Panja, the union of the streams from Little and Great Pamir. We have accounts of no passes immediately west of Baroghil, though certainly they exist. From Avi, near the boundary of Upper and Lower Káshgár, a pass crosses (about 72° E long.) to Ishrágh on the Panja. At the western limit of the section are the lofty passes of Nuksán, Kharteza, Agram, and Dora, which lead through the Badakhshan canton of Zebák to the Vardoj branch of the Kokecha or river of Badakhshan. On the "Nuksán" (quasi *Via Mala*) in descending towards Chitrál the traveller is girt with a leathern kilt, and slides down the snow. Ponies, with feet tied, are rolled down. "By these processes," says the native authority, "both men and beasts generally reach the bottom in safety."

(2.) The next section is that of which we know least. It embraces on the south Kafiristán, never yet penetrated by European traveller. There is a pass south to Kafiristán from Zebák and Sanglich, and one from Kurán, probably several more. The chief streams southward are that of Pech, joining the Kunar river at Chigar Serai (*Chaghanserai* of Sultan Baber), and the Alingar and Alishang, which unite in Laghman, formerly Lamghán (*Lambage* of Ptolemy), and join the Cabul river at Chárábgh above Jalálbád. West of Kafiristán are the Afghanized valleys of Tagao and Nijrao, hardly better known, and occupied largely by Pashais, a people seemingly akin to the Kafirs. On the north side the valleys form mir-ships or cantons among the congeries of small states owing allegiance to Badakhshan, and several of them having their peculiar dialect of old Persian affinity. One of these valleys is Kurán, down which flows the Jerm branch of the Kokecha. It is a wild glen near the borders of Kafiristán, coupled in a local rhyme with the jaws of hell, but which in the 8th century was of sufficient substance as a state to send a mission of homage to the Chinese court,—such disproportionate pretensions being probably due to its containing the mines of lazuli, famous for ages, commemorated by Marco Polo, and visited by Lieutenant Wood in 1838. Adjoining this are Mungán and Anjurnán, high valley cantons of which we barely know the names. Their streams chiefly bear north-west, and join the river of Taljkan, which carries them to the river of Kunduz, and so into the Oxus about 68° 18' E. long.

(3.) The last section extends from the borders of Kafiristán to the

Koh-i-Baba. On the south the drainage is received by two catchment channels flowing parallel to the watershed in opposite directions,—the Panjhir (or Panjshir) from the east, and the Ghorband river from the west, meeting near Charikar and flowing S.S.E. to meet the river from Cabul. The Panjhir valley is populous and fruitful, with irrigated orchards and mulberry gardens, the chief support of the people, though these, of Pashai kindred, have for ages borne a repute for ruthless turbulence. It contains silver-mines, worked at an early date, and early Mahometan coins bear the mint marks of secluded towns like Panjhir and Andaráb,—the latter place north of the mountains, head of a canton subject of Kunduz. From the Panjhir to the Andaráb valley lead at least seven passes. The chief of these is Khawak, crossed by Wood from the north in 1838, and nearly 1200 years before (644) by Hwen-Tsang from the south. The Túl Pass, a loop to this, was crossed by the great Timur on his advance to India (1398). From the Ghorband valley there are also seven or more passes; two ascend from Parwán, one of which, Sar-aulang, was attempted unsuccessfully by Wood and Lord in November 1837,—since crossed and surveyed by Havildar Hyder Shah (1870). Kúshán Pass, under the great peak, was ascended by Leech and Lord in October 1837. Four of the Ghorband passes descend on the lower Andaráb valley, two more on the Surkháb river, coming from the valleys about Bamian. The last, the pass of Shibr, ascends from the top of Ghorband valley, and descends on that of Bamian near the castle of Zohák. This was crossed by Hwen-Tsang in approaching India (630), and by Timur on his return (1399), and was commonly used by Baber, who calls it Shibrta. There remain the Koh-i-Baba passes of Irák, Hajjigak, and Pusht-i-Hajjigak. These are all approached from Cabul by the upper valley of the Cabul river and headwaters of the Helmand. The first Brigadier Dennie's force crossed to Bamian in 1840, before fighting Dost Mahomed on that famous site; Burnes (1832), Wood and Lord (1837), Griffith (1839), and others at that time crossed the Hajjigak, the best known of all the passes. North of the mountains the Andaráb river and the Surkháb form catchments like Panjhir and Ghorband rivers on the south. Uniting near Ghorí they form the river of Kunduz or Akserai (called by Baber *Doghába*) flowing north to the Oxus. Hazáras (see vol. i. p. 235) are the chief occupants of this section in its western portion. Further east on the north side the higher valleys are occupied by tribes of old Tajik lineage, mixed more and more with Uzbeks and other Turki people as the Kokcha is approached (see also vol. i. p. 241 sq.).

Geology.—Information is most scanty, and applies only to the western extremities of Hindú Kúsh. On the Kúshán Pass Lord speaks of the lower parts as consisting of micaceous schist, black slate with occasional bursts of granite, then mica slate and gneiss, and the summits of the pass and range of a granite core shooting up in precipitous peaks. On the Koh-i-Baba, also, Griffith speaks of the lower mass as predominantly of slaty formations; the summits of coarse quartzose grey granite, and of very compact brown quartzose rock. In the Irák Pass, and at Zohák, are masses of conglomerate. Limestone occurs in the upper part of the valley of Parwán, exhibiting large cavities, in one of which the stream is engulfed for two miles; also higher up the Ghorband valley, where a magnificent natural cavern occurs. Limestone occurs also on the Hajjigak Pass; and we hear of another great cavern near Doab, north of Bamian. Eruptive deposits occur in Ghorband valley towards Cháradé, and these recur at Bamian. Richthofen has supposed, from Chinese analogies, that the multitude of artificial caves and cave dwellings about Bamian indicate a loess deposit; such details as we have seen hardly to corroborate this.

The region is rich in minerals. Iron is abundant and widely diffused. Villages called *Ahangirán* (of the "iron-workers") are numerous. There is a rich black ore on the Hajjigak Pass, but fuel is entirely absent. Iron is also made at several places in Badakhshán, and of excellent quality in Bajaur east of the Kunar river. The districts adjoining the Jerni and Vardoj rivers are called Yamghán, which is popularly interpreted as *Hamah-Kán* ("All-Mines") from its various mineral wealth. Copper mines (not worked) exist here and also in Chitrál. Antimony is found in Ghorband, and accurate Griffith speaks of ore of antimony forming boulders and even "a large mountain" on the top of Hajjigak. Lead is found in Ghorband and in Yamghán.

Sulphate of zinc occurs in Ghorband; silver, as above mentioned, at the head of Panjhir; rock-salt on the borders of Badakhshán and Kunduz (mentioned by Marco Polo); sulphur in Yamghán and Sanglich (north of the Dora Pass); sal-ammoniac in Kurán. Orpiment is exported from Chitrál, a fact mentioned also by Hwen-Tsang. The lazuli of Kurán has been spoken of.

Zoology.—Of this we have not space to speak, nor accurate material. Afghanistan lies on the borders of the Oriental and Palæarctic regions (vol. vii. p. 269), and partakes in degree of both; but the Hindú Kúsh is to a certain extent a boundary between them. Thus it limits the genus *Salmo*, which is found in no Indian or Persian stream, but immediately on crossing the passes. The late estimable Russian traveller Fedchenko thought he had first discovered trout in Turkestan, but they were frequently caught by English officers at Bamian in 1840 and Marco Polo mentions them in Badakhshán.

Vegetation.—The only basis for a view of this would be Griffith's collections near Koh-i-Baba and in the Kunar valley, but they have not been analysed in such a sense. These general remarks by Hooker and Thomson are, however, apposite:—"The collections of Griffith, besides containing an immense number of Persian and European plants which find their eastern limits within the British territory, are rich in Himalayan forms which advance no farther west; and, what is of still greater importance, they contain many species common both to Europe and the Himalaya, but which, from mere differences induced by local causes in these two distant countries, might not be imagined to have a common origin, did not the Afghanistan specimens blend their characters or show the transition between them."—*Flora Indica*, i. 85, 86.

Historical Notices.—We have said that Hindú Kúsh is the Caucasus of Alexander's historians. It is also included in the Paropamisus, though the latter term embraces more, Caucasus being apparently used only when the alpine barrier is in question. Whether the name was given in mere vanity to the barrier which Alexander passed (as Arrian and others repeatedly allege), or was founded also on some verbal confusion, we cannot say. It was no doubt regarded (and perhaps not altogether untruly) as a part of a great alpine zone believed to traverse Asia from west to east, whether called Taurus, Caucasus, or Imaus. Arrian himself applies Caucasus distinctly to the Himalaya also. The application of the name Tanais to the Sir seems to indicate a real confusion with Colchian Caucasus. Alexander, after building an Alexandria at its foot (probably at Hupian near Charikar), crossed into Bactria, first reaching Drapsaca, or Adrapsa. This has been interpreted as Andaráb, in which case he probably crossed the Khawak Pass, but the identity is uncertain. The ancient Zend name is, according to Rawlinson, *Parosina*, the essential part of Paropamisus; this accounts for the great Asiatic Parnassus of Aristotle, and the *Pho-to-sin-a* of Hwen Tsang.

The name Hindú Kúsh does not appear, so far as we can ascertain, in any of the earlier Arab geographers. But it is used by Ibn Batuta, who crossed (c. 1332) from Andaráb, and he gives the explanation of the name which, however doubtful, is still popular, as (Pers.) Hindú-Killer, "because of the number of Indian slaves who perished in passing" its snows. Baber always calls the range Hindú Kúsh, and the way in which he speaks of it shows clearly that it was a range that was meant, not a solitary pass or peak (according to modern local use, as alleged by Elphinstone and Burnes). Probably, however, the title was confined to the section from Khawak to Koh-i-Baba (see Baber, pp. 136, 139). The name has by some later Oriental writers been modified into Hindú Koh (mountain), but this is factitious, and throws no more light on the origin of the title. The name seems to have become known to European geographers by the Oriental translations of the two Petis de la Croix, and was taken up by Delisle and D'Anville. Rennell and Elphinstone familiarized it, and Wilford willfordized about it. Burnes first crossed the range (1832). A British force was stationed at Bamian beyond it in 1840, with an outpost at Saighán.

The Hindú Kúsh, formidable as it seems, and often as it has been the limit between petty states, has hardly ever been the boundary of a considerable power. Greeks, White Huns, Samanids of Bokhara, Ghaznevides, Mongols, Timur and Timurids, down to Saddozais and Barakzais, have ruled both sides of this great alpine chain.

HINDUR, also called NALAGARH, one of the Punjab hill states, under the government of the Punjab, India, lying between 30° 54' 30" and 31° 14' 15" N. lat., and between 76° 39' and 76° 56' 45" E. long. Area, 256 square miles. The country was overrun by the Ghoorkas for some years prior to 1815, when they were driven out by the British, and the rājā was confirmed in possession of the territories. The estimated population in 1875 was 70,000; the estimated revenue £9000, and tribute £500. The principal products are opium and the usual grains.

HINDUSTĀN. See INDIA.

HINDŪSTĀNĪ,¹ or URDŪ, is a dialect of the Hindi, one of the seven languages of Aryan stock spoken at the present day in North India, the others being the Panjābī, Sindhī, Gujarātī, Marāthī, Bangālī, and Oriyā. The area over which it is spoken in North India may be said to be co-extensive with that of the Hindī, which is estimated at about 250,000 square miles, extending from the river Gandak in the east to the Sutlej in the west, and from the Himālaya in the north to the Vindhīyā mountains in the south. It is also extensively used, though in a somewhat different phase, in a great part of the Deccan, and is more-over the *lingua franca* of most parts of India.

As the Hindī language consists of many dialects, it is necessary to state that it is the Braj Bhāshā, or the dialect that is spoken in the districts of Agra and Mathura, and in the neighbourhood of Dehli, the ancient capital of the Mahometan empire, which is generally regarded as the parent of Hindūstānī. The grammatical structure and also a vast number of the commonest vocables of the Braj were incorporated in the new dialect, and to these were added a vast number of Persian, Arabic, and even Turkish words. "Such words, however, in no wise altered or influenced the language itself, which, as regards its inflexional or phonetic elements, remains still a pure Aryan dialect, just as pure in the pages of Walī or Saudā, as it is in those of Tulsī Dās or Bihārī Lal"² Peculiarities of composition, such as reversing the positions of the governing and the governed word (e.g., *bāp merā* for *merā bāp*), or of the adjective and the substantive it qualifies, or such as the use of Persian phrases with the preposition *ba* instead of the Hindī postposition of the ablative case (e.g., *ba-khushī* instead of *khushī se*, or *ba-ḥukm sarkār-ke*, instead of *sarkār ke ḥukm se*), are no doubt to be met with in many writings, and these, perhaps, combined with the too free indulgence on the part of some authors in the use of high-flown and pedantic Persian and Arabic words in place of common and yet chaste Hindī words, and the general use of the Persian instead of the Nāgarī character, have induced some to regard Hindūstānī or Urdū as a language distinct from Hindī. But such a view betrays a radical misunderstanding of the whole question.

¹ Hindūstānī (*lit.* "Of or belonging to Hindūstān") is the English name for the language. The natives generally call it *Urdū* or *Urdū Zabān*, "the camp language" (the word *Urdū* meaning, in Turkish, "a camp"), and the poets, *Rekhta*, "mixed;" while the phase of the dialect which is peculiar to southern India is termed *Dakhinī*, or "southern." The term *Hindī*, on the other hand, is derived from the Persian *Hind*, "India," and, strictly speaking, is applicable only to the modern language of the Hindūs. The old language, prior to the inroads of the Musalmāns, is termed *Hindūzī*, and is derived from Hindū. It may be added that the present article has reference only to the so-called High Hindūstānī, which differs considerably from the vulgar speech. This, in some parts of the area mentioned in the text, bears but little resemblance to the cultivated language, except in the possession of a few Persian or Arabic words. The High Hindūstānī is that which is uniformly employed in literature over the whole of the specified area. It is, moreover, the language in which the proceedings of the various Government courts and offices are carried on, and is spoken in its purity in all the large towns by the educated classes generally, by Hindūs as well as Musalmāns.

² Beames, *Comparative Grammar of the Modern Aryan Languages*, vol. i. p. 32.

As regards the introduction of foreign words into the various dialects of Hindī, it seems highly probable that it had its origin at an early period, perhaps as early as the 8th or 9th century of our era. But there is good ground for the opinion that, although the Hindī area was overrun as early as the 12th century, the Hindūstānī was not formed till the 16th century. "For many generations after the victories of Kutbu'd-dīn Aibak, the first Musalmān sovereign of Dehli, the conquerors retained their own Persian, and the conquered their Hindī. The Musalmāns had long been accustomed to speak pure Hindī, and it was not they who introduced Persian words into the language, but the Hindūs themselves, who at the epoch above mentioned were compelled by Todar Mal's new revenue system to learn Persian."³ And we learn from Mir Amman of Dehli (whose brief account of the origin of Urdū in the preface to his well-known *Bāgh-o-Bahār* bears on the face of it every convincing mark of probability, and, scanty as it is, is remarkable as, perhaps, the only attempt at a critical disquisition in the whole range of Hindūstānī literature) that at the date of the composition of his work (1802) the Musalmān dynasties had endured for a thousand years, and that as intercourse increased the languages of the Hindūs and Musalmāns became to a certain extent mixed. By the arrival and stay of the Amīr Tīmūr the camp or bāzār of the army was introduced into the city, whence the city bāzār was called Urdū, a Tartar word signifying "camp." "When Akbar ascended the throne, various races from all quarters, on hearing the kind patronage and bounty of that incomparable house, came and assembled in the royal presence, but the speech and dialect of each was different. From their being collected together, and owing to the trade, traffic, and intercourse which they carried on with one another, a single language, that of the Urdū (or Hindūstānī), was established."

The epoch of Akbar, which first saw a regular revenue system established, with toleration and the free use of their religion granted to the Hindūs, was, there can be little doubt, the period of the formation of the language. But its final consolidation did not take place till the reign of Shah Jahān. After the date of this monarch the changes are comparatively immaterial until we come to the time when European sources began to mingle with those of the East. Of the contributions from these sources there is little to say. Like the greater part of those from the Arabic and Persian, they are chiefly nouns, and may be regarded rather as excrescences which have sprung up casually and have attached themselves to the original trunk than ingredients duly incorporated in the body. In the case of the Persian and Arabic element, indeed, we do find not a few instances in which nouns have been furnished with a Hindī termination, e.g., *kharīdnā*, *badalnā*, *guzarnā*, *dāghnā*, *bakhshnā*, *kamīnapan*, &c. But the European element cannot be said to have at all woven itself into the grammar of the language. It consists, as has been observed, solely of nouns, principally substantive nouns, which on their admission into the language are spelt phonetically, or according to the corrupt pronunciation they receive in the mouths of the natives, and are declined like the indigenous nouns by means of the usual postpositions or case-affixes.⁴ A few examples will suffice. The Portuguese, the first in order of seniority, contributes a few words, as *kamarā* or *kamrā* (camera), "a room;" *mārtol*, "a hammer;" *nilām*, "auction" (often corrupted

³ Beames, *Ibid.*, vol. i. p. 30, note.

⁴ It is supposed, however, that the strange dialect in which the Lascārs, or "native seamen," and the Dāndīs, or "boatmen," hold converse, and in which orders are given to a native crew regarding the working of a ship, is compounded of Portuguese words assimilated to Hindūstānī in their terminations and inflexions. Of this there is no positive proof, and until the matter has been properly and satisfactorily investigated it would be injudicious to pronounce a decided opinion.

into *lilām*); *perā*, "a turkey," &c. &c. Of French and Dutch influence scarcely a trace exists. English has contributed a number of words, some of which have even found a place in the literature of the language; e.g., *Kammishanar* (commissioner); *jaḥ* (judge); *isṭant* (assistant); *dākṭar* (doctor); *dākṭari*, "the science of medicine," or "the profession of physicians;" *inspekṭar* (inspector); *sosayāṭi* (society); *apīl* (appeal); *apīl karnā*, "to appeal;" *dīkrī* or *digrī* (decree); *digrī* (degree); *inch* (inch); *ful* (faat); and many more, are words now commonly used. How far the free use of Anglicisms will be adopted as the language progresses is a question upon which it would be hazardous to pronounce an opinion.

The grammatical structure of the Hindūstānī differs in no essential particular from that of the Hindī from which it is sprung. It is therefore of the rise and formation of this language, and of the stage to which it had attained when the new phase of the Hindūstānī was developed from it, that we shall now speak.

Of the history and development of the Hindī or Hindū language previous to the 11th century of our era little or nothing is known. It is accepted as a fact by most scholars that Sanskrit ceased to be a vernacular in the 6th century B.C., when the Buddhist religion was founded, which for ten centuries drove Brāhmanism into obscurity. From that time the Aryan people of India spoke popular dialects called Prākṛits,¹ and it is from these that the modern Aryan tongues are mainly derived. These Prākṛit dialects are generally grouped under five heads, viz., the Maharāshtrī, Sanrasenī, Māgadhi, Paisāchī, and Apabhraṅsa. Of these the Saurasenī, or dialect of Saurasena, the modern tract of Mathurā and the surrounding country, is taken to be the parent of the Hindī, or at any rate of that phase of it with which we have to do. These Prākṛits were, like the Sanskrit, synthetical and inflexional in their structure, and certainly continued to be so up to the 1st century of our era, the lowest stage to which in point of development scholars have been able to reach. At what precise period the synthetical structure of the Prākṛit began to break up and to give place to the analytical formations of the modern speech it is impossible to tell. The gap of nine centuries has yet to be filled up. And unless future discoveries of Buddhist literature should shed light on the subject, it is to be feared that the history of this period will ever remain unknown.

The dawn of modern Hindī may be dated from the 11th century. The earliest known writer in the language was Chand Bardāi (c.1200), whose epic is in a dialect rude and half-formed, but as decidedly analytical as the Hindī of the present day.² Much of the old synthetical structure no doubt is still to be found in the work; the particles and the auxiliary verbs are in a very crude and unformed state (as, for example, the use of an obscure *ka* for the modern genitive affix *kā*, which *ka* does not vary with the governed noun, and is frequently left out altogether; the total absence of the ordinary substantive verb *hai*, &c.); but these crudities and remnants of old Prākṛit forms do not affect the general structure. Indeed, they are to be found in writings of a much later period, in works belonging to the 14th and 15th centuries, e.g., in the *Adī*

¹ Prākṛit is derived from the Sanskrit *prakṛiti*, "nature," and signifies "natural," "not accomplished," "vulgar." It is the collective name of those dialects which are immediately derived from, or which stand in an immediate relation to, Sanskrit, or "the polished or accomplished language" of the Hindīs.

² It is this striking change from the synthetical structure of the Prākṛit to the analytical of the Hindī, coupled with an accidental resemblance in certain of the case-affixes to those of the Dravidian tongues, that has led some Oriental scholars to claim for Hindī a non-Aryan descent. But this view is ably combated by Mr Beames in his *Comparative Grammar of the Aryan Languages of India*, and by Professor Rudolf Hoernle, in his *Essays on the Gaurian Languages*.

Granth, the language of which exhibits, according to Trumpp, "grammatical forms not firmly fixed, but rather in a state of transition." And although the forms assume greater fixity, and marked progress is observable in the works of later writers in the Braj Bhākhā dialect, e.g., in those of Kabir, Sūr Dās, Nabhā Jī, Kesava Dās, and Bihārī Lāl (whose poems are, as a rule, composed in very pure and elegant Hindī), we still find certain crudities and traces of Prākṛit forms and organic structure, and these continue even in the language of the present day.

To give a minute account of the grammatical formation, to indicate the various phonetic or glottic laws by the operation of which the vocables and grammatical forms of the Hindī are derived from those of the Prākṛit or Sanskrit, is beyond the scope of the present article. We can but notice a few general laws, and exhibit results, so far as they have been ascertained. For closer acquaintance with the subject we must refer the reader to the *Prākṛit-Prakāsa* of Vararuchi, edited by Professor E. B. Cowell; the *Prākṛit Grammar* of Hemachandra, edited by Professor Pischel; the *Comparative Grammar of the Modern Aryan Languages of India*, by John Beames, B.C.S.; and *Essays on the Gaurian Languages*, by Professor Rudolf Hoernle.

Prākṛit tolerates no compound consonant in the beginning and no dissimilar consonant in the middle of a word. Two dissimilar consonants in a Sanskrit word are changed in Prākṛit to two similar consonants, and occasionally one of these is elided and the preceding vowel lengthened. In the modern dialects this elision of one consonant and compensatory lengthening of the preceding vowel is the rule. Prākṛit either changes a medial surd mute consonant to the corresponding sonant one, or elides it altogether; and it generally changes an aspirate mute consonant to the simple aspirate *h*. In fact the modern Aryan tongues stand to the Prākṛit and the Sanskrit in a relation very similar to that existing between the Italian, &c., and the Romance and Latin languages. Hindī "is not the daughter of Sanskrit, as we find it in the Vedas, or in the later literature of the Brāhmins, it is a branch of the living speech of India, springing from the same stem from which Sanskrit sprang when it first assumed its literary independence."³

Vocables.—The vocables may be classed under three heads:—
1. Words which are pure Sanskrit, as *rājā*, "a king"; *pitā*, "father"; *kavī*, "a poet"; *nāgarī*, "of or belonging to a city"; *karma*, *kārya*, "work"; *krodha* (vulg. *krodh*), "anger." Not a few of this class of words have existed in the language for some centuries; some are to be found even in the oldest specimens of the literature; but by far the larger number have passed into the language during the present century, and the introduction is still progressing. The form in which they appear is that of the Sanskrit nominative singular.

2. Words which are derived from the Prākṛit, and have been considerably changed in the process, though not so much as to obscure their origin, e.g., *kām*, "work," Prk. *kaṃma*, S. *karma*; *kān*, "ear," Prk. *kaṇṇa*, S. *karna*; *āṭh*, "eight," Prk. *aṭṭha*, S. *uṣṭha*; *hāth*, "hand," Prk. *hattha*, S. *hastā*; *āp*, "self," Prk. *appā*, S. *ātmā*; *bāt*, "word," Prk. *vattā*, S. *vārtā*; *āj*, "today," Prk. *ajja*, S. *adya*; *āge*, "before," Prk. *agge*, S. *agre*; *āy*, "fire," Prk. *aggi*, S. *agni*; *dūdḥ*, "milk," Prk. *duddha*, S. *duग्धा*; *phāgun*, "Feb.-March," Prk. *phaggun*, S. *phāḡṇun*; *buddhā*, "old," Prk. *vuddho*, S. *vṛiddhah*; *kohā*, "said," (Braj *kahyan*), Prk. *kahido*, *kahio*, S. *kathitah*; *rahā*, "remained," (Braj *rahyan*), Prk. *rahido*, *rahio*, S. *rahitah*; *thā*, "was," Prk. *thio*, S. *sthitah*. This is by far the largest class of words in the Hindī. And, as in the case of the first class, they are adopted in the form of the nominative singular of the Prākṛit. They are divisible into two classes, the first comprising such as have in their declension preserved traces of the old organic inflexion of the Prākṛit declension, and the second those which have preserved no such traces. As regards these it may be observed that the terminations *ā*, *e*, *i*, *o*, *ū*, of the Prākṛit are regularly reduced in the Hindī to their inherent simple vowels, viz., *ā* to *a*, *e* and *i* to *i*, and *o* and *ū* to *u*; and these short vowels arc, as a rule, made quiescent, so that a word ending in reality in a short vowel virtually terminates in a consonant; and, not being pronounced, the final short vowel is frequently suppressed in writing also.

³ Max Müller, *Lectures on the Science of Language*, lect. ii.

3. Words which cannot apparently be traced to any Sanskrit original, and are therefore considered by some scholars as words of non-Aryan origin; e.g., *pagri*, "turban"; *gor*, Prk. *goram*, "leg." Such words form but a small proportion; and it is probable that further research and a better acquaintance with the laws of development of the modern Aryan tongues will ultimately enable scholars to very much diminish their number.

Gender.—The three genders of the Prākṛit and Sanskrit are, in Hindī and Hindūstānī, reduced to two, the neuters and masculines of the old tongues generally becoming masculines in the modern language. Instances, however, are not a few in which they are changed to feminines. A striking feature in the modern tongues is the preponderance of masculines ending in *ā*, with the corresponding feminines in *ī*. Now in the Sanskrit *ā* is a typical feminine ending, and *ī* is as often a masculine as a feminine termination. Many feminine words ending in *ā* are no doubt to be found in the Hindī, as *chhīmā*, "patience," = S. *kṣamā*; and similarly many masculine words which in the Prākṛit and Sanskrit terminate in *ī* are also to be met with, as *pānī*, "water," = S. *pānīyam*; *hāthī*, "elephant," = S. *hastī* (*hastin*). But *ā* is typically a masculine and *ī* a feminine termination in the Hindī and Hindūstānī, and this is probably due to the number of sources from which the termination springs; thus we have—(1) *ā* = Prk. *a*, = S. *as* or *ah*, e.g., *kaisā*, "like what," "what manner," "how," Prk. *kērisa*, S. *kidriśah*; (2) *ā* = Prk. *aḥ*, = S. *akāś* or *akāḥ*, e.g., *ghorā*, "horse," Prk. *ghoraḥ*, S. *ghotakuh*; (3) *ā* = Prk. *a(k)am*, *aam*, = S. *am*, e.g., *kelā*, "plantain," Prk. *kerakam*, *kerām*, S. *kaduram*. Again, the masculine ending *oka* of the old languages has a corresponding feminine in *ikā*; and as the Prākṛit commonly employs the plosive increment *k* to raise bases to the form *aka*, so it employs the same affix to form the feminine *ikā* of these masculines; *ikā* becomes *iyā*, and more commonly *ī* in the modern tongues. The form *iyā* is that which is generally used in feminine diminutives; e.g., *dībīyā*, "a tiny box"; but it is also used like *ī* for a simple feminine; e.g., *kutlā*, "dog," *kutiya*, "bitch"; *būhā*, "old man," *burhīyā*, "old woman." If to the above class of feminines ending in *ī* be added the large class which in Prākṛit and Sanskrit form the feminine in *ī* (i.e., the Prākṛit masculines in *a*, = S. *as*), the preponderance of nouns ending in *ī* seems sufficiently accounted for. It may be added that *ā* and *ī* are so universally regarded as masculine and feminine terminations respectively that the natives employ them freely in forming feminines from masculines and vice versa, e.g., *badlā*, *badli*, from the Arabic *badal*. There are a few other feminine terminations which are worthy of notice, not so much on account of their origin (which presents no difficulty), as on account of the free use which is made of them; these are—(1) *inī*, *in*, *an*, *nī*, = S. *inī* (fem. of *in*, *i*); (2) *ānī*, *āni*, *āin*, = S. *ānī*. These are not only found in words derived from the Prākṛit, but are added to Persian and even Arabic words; e.g., *hāthīnī*, *hāthin*, *hathinī*, "female elephant," (= S. *hastinī*); *sunārīn*, *sunāran*, "a goldsmith's wife," (fem. of *sunār*, "goldsmith," = S. *suvarnakāra*); *shernī*, "tigress," from the Persian *sher*, "tiger"; *naṣībān*, a proper name, from the Arabic *naṣīb*; *paṇḍitānī*, "the wife of a pandit"; *chaudhrānī*, "the wife of a *chaudhrā* or head-man"; *mīhtrānī*, "the wife of a sweeper, a sweeper-woman," from the Persian *mīhtar*, "a sweeper."

Declension.—It is here that the most striking contrast between the old and the new languages is found. The synthetical method of the Prākṛit and the Sanskrit is, as a whole, rejected, only certain half-effaced traces of declension being retained. The number of cases, as in the Sanskrit, is seven, the nominative, accusative, instrumental, dative, ablative, genitive, locative, and vocative; but the inflexions of the Prākṛit have given place to case-affixes or postpositions. For example, where the Sanskrit has *śivāyai* and *śivasyai*, the Hindī has *śiv-ko*, and *śiv-kā*.

The case-affixes or postpositions are as follow:—

Instrumental	<i>ne</i> , "by."
Dative-Accusative	<i>ā</i> , "to," "for."
Ablative	<i>se</i> , "from."
Genitive	<i>kā</i> (<i>ke</i> , <i>kī</i>), "of."
Locative	<i>meṅ</i> , <i>par</i> , "in," "on."

The genitive affix, it may be observed, varies its termination so as to agree with the governing noun. In other words, it is adjectival, and agrees with the governing noun just as an adjective would; e.g., *some-kī gharī*, "a gold watch."

The case-affixes or postpositions are all, there can be no doubt, remnants of Prākṛit nouns which were probably in use at the period when the modern Aryan languages began to be formed. The majority of these are fairly determined, and it seems probable that the remainder will also be fixed before long. The results of the investigation of scholars, as regards the postpositions noticed above (which are those commonly employed in the declension of Hindī and Hindūstānī nouns), we will here attempt to exhibit.

The case-affix *ne* of the instrumental (or case of the agent) is regarded by Trumpp and others as derived from *ena*, the instrumental case-ending of the Sanskrit. This opinion is, however, combated by Beames (*Comp. Gram.*, vol. ii. p. 266 *et seq.*), who is of opinion that it is an affix of the dative, which was probably transferred to

the instrumental as late as the time of Shāh Jahān, in whose reign, as has been shown above, Urdū or Hindūstānī was consolidated. Beames shows that the postposition is not used in the old Hindī, and is not to be found in most of the dialects, except as a dative; but he does not, we believe, trace it to any particular original. It is clear, however, that whether this affix is derived from the instrumental case-ending of the Sanskrit or not, it bears a striking resemblance to the latter in its use and the construction it requires; e.g., the Sanskrit *tena uktam* is marvellously like the Hindī *us-na kahā*, "by him it was said," or freely "he said."

The dative postposition *ko* is derived by Dr Trumpp from the Prākṛit *kiṭo*, *kiō*, = S. *krītam*. Dr Hoernle,¹ however, would seem to connect it with the Bangālī *kāchhe* "near," and the S. *sa-kāsa*; and Beames (*Comp. Gram.*, vol. ii. p. 257), accepting this as a right clue, traces the affix to the Prākṛit *kakham*, = S. *kaksham*, "arm-pit," "side," the locative of which, *kakshhe*, he believes to be the source of the Bangālī *kāchhe*.

The postposition *se* of the ablative is traced by Beames (*Comp. Gram.*, vol. ii. p. 274) to the Sanskrit *samam*, "with," through an old form *soṅ* still used in the rustic dialects.

The genitive case-affix *kā* (fem. *kī*, oblique *ke*) is derived by Trumpp and others from the Sanskrit affix *ka*. But Hoernle² shows conclusively (and his derivation is accepted by Beames) that the affix is derived from the Prākṛit *karīō* (= S. *krītas*), which becomes *kero*, *kerak*, and then *kerāō*; *kero* is then shortened to *karā*, whence the modern form *kā*.

Of the locative case-affixes, *meṅ*, "in," is derived by scholars from the Sanskrit *madhye*, the locative of *madhya*, "the middle"; while *par* (*parī*, or *pai*) is obviously traceable to the Sanskrit *uparī*, "upon."

The declensions are two in number. In the one the nominative or base is inflected before the case-affixes are added; in the other no change takes place in the nominative form. The first consists solely of masculine nouns ending in *ā* = Prk. *o* = S. *as* (e.g., *ghorā*, "horse," = Prk. *ghoraḥ*, = S. *ghotakas*); the second comprises all other nouns, whether they end in vowels or consonants. The base of the first declension is inflected by changing final *ā* to *e*; e.g., nom. *ghorā*, inflect. base *ghore*, gen. *ghore-kā*, dat. *ghore-ko*. But in the second declension we find, nom. *rājā*, "king," gen. *rājā-kā*, "of a king," &c. Dr Hoernle connects the *e* of the inflected base with the *yā* of the oblique form in Marāṭhī, and so traces it to a Prākṛit genitive in *yassa* = *iassa* = *ikassa*. The correctness of this derivation would seem to be established by the analogy of the oblique or inflected base of the plural of nouns, and especially by the inflected base of the pronouns, both these bases being indisputably traceable to the Prākṛit genitive. Mr Beames, however, is of opinion that "it is not correct to derive the oblique form from any special case of the Sanskrit;" he thinks that "it rather results from a general fusion of all the cases" (*Comp. Gram.*, vol. ii. p. 210). This is the more remarkable as he accepts without demur the fact that the plural oblique base is a corruption of the Prākṛit genitive plural.

The terminations of the nominative plural of nouns (where a plural form is used) are clearly traceable to the Prākṛit. Nouns which fall under the first of the declensions noticed above terminate in *e* in the nom. plur. (e.g., *ghorā*, "horse," nom. plur. *ghore*, "horses," which is identical in form with the inflected base of the sing.). The termination *e* = Prk. *e*, = S. *āh*. Feminines ending in a consonant (and also fem. Arabic words ending in *ā*, as *balā*), form the nom. plur. by adding *oi* to the sing. nom. This ending, *oi*, = Prk. neuter *ai*, *āin*, = S. neut. *āni*. The plur. termination *ān* of the nom. of feminines ending in *ī* (as *betī*, "daughter") is also to be referred to the Prākṛit *āin* = S. *āni*. The oblique form of the plural of all nouns ends in *oi* (e.g., *ghoroṅ*; gen. *ghoroṅ-kā*; *rājā-oi*, dat. *rājā-oi-ko*). The termination *oi* is derived from the Prākṛit *ānam* (= S. *ānām*), the termination of the genitive plural.

Pronouns.—The pronouns stand in marked contrast to the nouns in respect of the fidelity with which they have preserved the Prākṛit forms. Those of the first and second persons run parallel to one another, and have four fundamental forms, namely, the nominatives and the obliques in both numbers. The genitive is a possessive pronoun, and, as in the noun, is adjectival in form. *Main*, "I," is derived by Trumpp from the Prākṛit *mam*, the accusative of *aham*; but it seems more probable that it is, as Beames shows, the instrumental *maim* of the Prākṛit, and = S. *mayā*. In the genitive *me-rā*, "my," the affix *rā* added to the Prk. base *me* is, there can be little doubt, connected with the affix *kā*, used in forming the genitive of nouns; the form *karā*, by elision of *k* would naturally yield *rā*, which we may observe is the genitive affix of nouns also in the Marwāri dialect of Hindī. The oblique form *mujh* is derived from the Prākṛit *majjha*, one of the forms of the genitive. The dative-ac. *mujhe* of the modern Hindī is formed by adding *e* to *mujh*, this *e* being the usual sign of the oblique in nonus. *Ham*, "we," = Prk. *anhhe* by transposition of *h*. This is now commonly used as the oblique form of the plural (e.g., *ham-ko*, *ham-par*); but the oblique *hamoṅ*, = Prk. gen. plur. *amhānam*, is also to be met with.

¹ *Journal of the Asiatic Society of Bengal*, 1872, pt. 1, p. 174 *et seq.*

² *Ibid.*, p. 124.

The genitive plural *hamārā* is probably from Prk. *amha* + *karo*, by elision of *k*.

The pronoun *tū*, "thou," = Prk. *tumam*, *tuām*, = S. *tvam*. A form *tañi*, parallel to *maiñ*, and similarly derived, is also in use. The oblique *tujh* is from the Prakrit *tujha*, one of the forms of the genitive. The sources from and the processes by which the remaining forms are obtained are precisely parallel to those employed in the pronoun of the first person.

The pronouns of the third person are identical with the demonstrative pronouns *yah* or *yih*, "this," and *wah* or *wih*, "that," of which the older forms are *iñ* and *uh*. The origin of these forms has not yet been discovered. All that can be gathered respecting them is that they are probably connected with one or other of the Prakrit forms *aām*, *iām*, *inam*, *im*, &c. = S. *ayam*, *m*, *iyam*, *f*, *idam*, *n*, &c., and are to be referred to primitive bases *i* and *a* or *u*. The oblique forms of these pronouns, however, point clearly to the Prakrit genitive, e.g. *is* = Prk. *assa*, S. *asya*.

The relative pronoun *jo*, "he who" = Prk. *jo*, base *ja* = S. *ya*. The other form in use, *jaun*, = Prk. *jo-uṇa* (= S. *punah*). The singular oblique form *jis* = Prk. *jissa* (the fem. base *ji* being used in place of the masc. *ja*), = S. *yasya*. The oblique form of the plural, i.e., *jin* = Prk. *jānam* (by weakening of the vowel), = S. *yānam*.

The correlative *so* = Prk. *so* = S. *sah*. Its remaining forms may be made on the model of *jo* by substituting *i* for *j*.

The interrogative pronoun has *k* for its typical letter, just as the relative has *j*, and is in all respects as uniform as the relative and correlative. *Kaun*, "who" = *ko* + *uṇa* (= S. *punah*); the oblique form *kis* = Prk. *gen. kassa* (with change of base from masc. *ka* to fem. *ki*), = S. *kasya*.

The indefinite pronoun *koī*, "some one," = Prk. *kobī*, = S. *ko* + *api*. The oblique form *kisi* shows the oblique of the interrogative with the *i*, whose origin has been forgotten, so that it is regarded as a mere emphatic particle" (see Beames, *Comp. Gram.*). *Kuchh*, "something" = Prk. *kimchi* = S. *kimchit*.

The reflexive pronoun *op*, "self" = Prk. *appā*, *āpā*, = S. *ātma*.

Verbs and Tenses.—The verbal stems are, generally speaking, derived from the Prakrit present tense of Sanskrit neuter verbs, or from the Prakrit passive past participle. In the formation of the tenses, as in the declension of nouns, the synthetical or inflexional system of the Prakrit and the Sanskrit has given place to the analytical. Still wrecks of the old inflexions remain.

The tenses of the modern verb may be naturally classed under three heads—(1) the simple tenses, which are the exact modern equivalents of corresponding tenses in the Prakrit verb, and in which traces of the old synthetic method still linger; (2) tenses formed of a participle, either the imperfect or the perfect participle; (3) tenses formed of a participle and an auxiliary verb.

The tenses of the first class are two in number,—the aorist (which corresponds to the present indicative of the old languages), and the imperative, which is derived from the Prakrit imperative.

The terminations of the aorist are:—

Singular.		Plural.	
1. āñ = Prk. āñi = S. āñi.	2. e = Prk. asi = S. asi.	1. eñ = Prk. āma, ama = S. āmah.	2. o = Prk. aha = S. a-tha
3. e = Prk. adi, ai = S. att.		3. en = Prk. antf = S. anti	

The imperative closely resembles the aorist or old present. The second person sing. is the bare verbal stem, and the second person plur. is identical with that of the aorist.

From the aorist the Hindustāni and the Hindi form the simple future by the addition of *gā* (= Prk. *gañ*, *goda*, = S. *gatah*, perf. part. of the root *gam*, "to go"), e.g., *kahūñ-gā*, "I will tell," &c. The termination *gā* (which is masc.) becomes *gi* for the feminine, and *ge* for the plural, after the analogy of nouns of the first declension.

Of the tenses of the second class little need be said. The participles (which like other vocables are derived from the Prakrit) are the imperfect and the perfect, or what are vulgarly termed the present and the past. An example of each will suffice to show the construction: *wah boltā*, "he says"; *maiñ bolā*, "I said"; *wah bolī*, "she said"; *we bole*, "they said." Such is the construction in the case of neuter and intransitive verbs. But if the verb be active transitive, the tenses formed of the perfect passive participle are passively constructed; the place of the nominative is taken by the instrumental or case of the agent, and the participle inflects so as to agree with the object, if this be expressed, and appear in the form of the nominative; but if the object is not expressed, or if when expressed it assumes the dative form, the participle is constructed impersonally and appears in the masc. sing. form; e.g., *maiñ-ne kahā*, "by me it was said," "I said"; *us-ne chitthi likhī*, "the letter was written by him," "he wrote the letter"; *rajā-ne shernī-ko marā*, "the king killed the tigress"; lit. "as regards the tigress, it was killed by the king." This construction, as we have already remarked, is commonly employed in the Sanskrit.

The tenses of the third class are formed by adding to the participles already mentioned the various tenses of certain auxiliary verbs, as *honā*, "to be"; *jānā*, "to go"; and the fragmentary forms *hūñ* (with its remaining persons) and *thā*; e.g., *maiñ jāñā hūñ*. "I

am going"; *wah parhī hai*, "she is reading"; *wah bañhā thā*, "he was seated," "he was sitting"; *we chale hoñge*, "they will have started."

Of these auxiliaries *honā* (*ho* = Prk. *ho*, = S. *bhū*) and *jānā* (*ja* = Prk. *jā*, = S. *yā*) need not detain us. Both verbs are in use in all their tenses in the modern languages, and the preceding remarks on the verbal forms and tenses apply equally to them. *Jānā* is that which is employed to form the passive voice, e.g., *wah mārā jāgē*, "he will be killed." It is also used for other purposes, such as intensifying a root to which it is attached, &c.

The auxiliaries *hūñ* (with its other persons) and *thā* stand on a different footing. The former is derived from the present indicative of the root *as*, "to be," in the old languages:—

Singular.		Plural.	
1. hūñ = Prk. amhi = S. asmi.	2. hai = Prk. asi = S. asi.	1. haiñ = Prk. asma = S. smah.	2. ho = Prk. altha = S. stha.
3. hai = Prk. atthi = S. asti.		3. haiñ = Prk. santi = S. santi.	

The latter is derived from the Prakrit *thāo*, = Sanskrit *sthitañ*, the perfect participle of the root *sthā*, "to stand." Besides being used as auxiliaries, both are employed to express simple existence, as *maiñ hūñ*, "I am," "it is I"; *wah hai*, "he or it is"; *wah thā*, "he was"; *wah thī*, "she was" (J. T. P.)

HINDUSTANI LITERATURE.—Hindustani literature falls into two great divisions, of which the first is comprehensively styled Hindi, the second Urdū. Both of these forms of speech are, in their application to literary purposes, at first intruders upon the ground already occupied by the learned languages, Sanskrit and Persian. At no time during modern Indian history has Sanskrit altogether ceased to be used for composition by the class who regard culture and literature as their special heritage, although during the last two centuries it has much fallen from its former estate; and Persian has been still less neglected by learned Muhammadans and their Hindu imitators in India. But there is this difference between them that, whereas Hindi has been raised to the dignity of a literary language chiefly by impulses of revolt against the monopoly of the Brahmans, Urdū has been cultivated with good will by authors who have themselves highly valued and dexterously used the polished Persian. Both, however, represent the popular side of the national culture, and in the present day they are almost in sole possession of the field. The subject may be conveniently divided as follows:—

1. Early Hindi, of the period during which the language was being fashioned as a literary medium, represented by the old heroic poems of Rājputānā and the literature of the *Bhagats* or Vaishnava reformers, and extending from about 1200 to 1570 A.D.

2. Middle Hindi, representing the best age of Hindi poetry, and reaching from about 1570 to 1750 A.D.

3. The rise and development of literary Urdū, beginning about the end of the 16th century and reaching its height during the 18th.

4. The modern period, marked by the growth of a prose literature in both dialects, and dating from the beginning of the present century.

1. Early Hindi literature has as yet been very insufficiently explored. Chand's *Prithvirāj Rāsau* is the only specimen of the heroic ballads of which any portion has been published, other ancient metrical chronicles of the same character being known to us only from the use made of them by such writers as Colonel Tod in his *Annals of Rajasthan*, and Major Pogson in his *History of the Boondelas*. Chand was the bard of Prithvirāj, the last Hindu king of Delhi, whose life and death he has related. He was himself a native of Lahore, which had for nearly 200 years (since 1023) been under Musalmān domination at the time when the poem may be supposed to have been written. His language exhibits a considerable proportion of Persian words, but little of the distinctive features of what is now Panjābi. His work is probably, with the

Beames (*Comp. Gram.*, vol. iii, p. 171, & seq.) thinks it difficult, if not impossible, to derive these modern forms from the old ones given above, and would postulate the existence of a present tense of the root *as* conjugated after the *bhū* type, thus—(sing.) 1. *asām*; 2. *asasi*; 3. *asati*; (plur.) 1. *asānah*; 2. *asathā*; 3. *asanti*. The objection to this, however, is that no such forms have been found to exist.

exception of a fragment by Jaideo (the author of the Sanskrit *Gītā-Govinda*), preserved in the *Ādi-Granth*, the oldest specimen of Hindī which we possess: but it is impossible to suppose that he was the first to attempt poetical composition in that language. The metrical perfection of his verse alone shows that he must have had many predecessors; and rude and rough though his utterance is, it abounds in poetic conventionalisms which must have been the common stock of many singers of his class. The story is told in sixty-nine books, of which some are interludes and digressions, but most are occupied with the exploits of the hero and his warriors. Considering the early date of the poem, and the opportunities of knowing the truth which the author (if he was really Prithwīraj's bard) possessed, it is remarkable how much legend and fiction is mixed up with history in the chronicle. The repeated conflicts between the rājā and Sultān Shihābuddīn of Ghor, in which the latter always, 'except in the last great battle, comes off the worst, and is released on payment of a ransom, seem to be entirely unhistoric, our authorities knowing only one encounter (that of Tiraurī near Thānesar, fought in 1191) in which the sultān was defeated, and there even he escaped uncaptured to Lahore. The Mughals (Book xv.) are brought on the stage more than thirty years before they actually set foot in India (1222), and are related to have been vanquished by the redoubtable Prithwīraj. These and other points make it questionable whether we have here, at least in its entirety, a genuine contemporary work; but we may concede, as indeed we are justified in doing by the language of the poem, that it is one of our earliest documents in Hindī.

It is very difficult for us now to form a just estimate of Chand's poem: the language, essentially transitional in character, abounds in strange forms which have long since died out of the vernacular speech; few if any Hindus, even the most learned, are able to interpret him; and his meaning must be sought by investigating the processes by which Sanskrit and Prakrit words have been transfigured in their progress into Hindī. But upon the whole he may be said to exhibit both the merits and defects of ballad-chroniclers in general. There is much that is lively and spirited in his descriptions of fight or council; and the characters of the Rājput warriors who surround his hero are not unfrequently sketched in their own words with skill and animation. The sound, however, too often predominates over the sense, and we find abundantly exemplified in his poem the wearisome iteration, uninventive sameness of machinery, and tedious unfolding of familiar themes and images which distinguish nearly the whole of Indian narrative poetry. His value, for us at least, is linguistic rather than literary.

The other class of composition which is characteristic of the period of Old Hindī, the literature of the *Bhagats*, both possesses more intrinsic interest and has exercised a more important influence on subsequent literary endeavour. The heroic chronicles, with perhaps the single exception of a famous saga relating the history of Padmāvati, wife of Ratan Sen Rājā of Chitor, who in 1303 at the taking of that fortress by Sultān 'Alāud-dīn burnt herself and (so says the tale) 13,000 other women rather than fall into the hands of the conqueror, which has been several times handled by poets outside the pale of Rājput traditions, and especially in a still highly esteemed work by Jaisī under Sher Shāh (1540), had only a local currency, and contributed but little to the furtherance of literature outside the limits of Rājputānā. The Vaishnava reformers, on the other hand, exercised the most powerful influence both upon the national speech and upon the themes chosen for poetic treatment. Nearly the whole of subsequent Hindī literature is impressed with one or

other form of Vaishnava doctrine; a very large proportion of the poets whose works are still current among the people were Vaishnava saints or *bhagats*; and to their initiative is due the almost exclusive use as a poetic dialect of that form of archaic Hindī known as Braj-bhākhā. Vaishnavism was essentially a reaction against Brahmanical influence and the chains of caste, a claim for the rights of humanity against the monopoly which the "twice-born" asserted of learning, of worship, of righteousness. As Śiva was the peculiar deity of the Brahmans, so was Vishṇu of the people; and while the literature of the Śaivas and Śaktas is almost entirely in Sanskrit, and exercised little or no influence on the popular mind, that of the Vaishnavas is mainly in Hindī, and in itself constitutes the great bulk of what has been written in that language.

The Vaishnava doctrine is commonly carried back to Rāmānuja, whose appearance is placed by Wilson about the middle of the 12th century. He was a native of Southern India, and had few immediate followers in the north. In the latter region the new opinions were spread by Rāmānand, whom the *Bhaktamālā* makes the fourth head of the sect, and other authorities the fifth; both Wilson and Trumpp place him about 1400 of our era. Nothing in Hindī by Rāmānuja has come down to us; of Rāmānand we have one short poem in the *Granth* (Introduction, p. exxiv.). Between Rāmānuja and Rāmānand (though not in the line of teachers descending direct from the former) we may place Jaideo (about 1250) and Nāmdeo (about 1300), of the first of whom we have a fragment in the *Granth*, and of the second six pieces have been similarly preserved. Jaideo was a Brahman, and well acquainted with Sanskrit; but Nāmdeo (or Nāmā) was a *chhīpī* or calico-printer, a very despised class, and was perhaps the first to proclaim among the followers of the new doctrine the essential unity of mankind as worshippers of Hari. Kabir comes next, and is incomparably the greatest, in the order of Vaishnava teachers. He was a weaver by caste, and in all probability originally a Musalmān. He is counted among the twelve disciples of Rāmānand; but he seems himself to trace his spiritual paternity rather to Jaideo and Nāmā.¹ He dwelt first at Benares and afterwards at Magahar, in the present district of Gorakhpur, during the reign of Sikandar Shāh Lodī (1488-1517), and was probably dead before the end of the 15th century. Nānak, the first Guru of the Sikhs, whose *Granth* is little more than a paraphrase of Kabir's writings, was born in 1469 and died in 1538; and from the relation between the two it seems necessary to suppose that Kabir was several years the senior.

The works attributed to Kabir are very numerous; they are preserved complete at the headquarters of the sect, the *Kabir chaurā* at Benares, and many portions of them have been separately printed and lithographed in India. The best known are those entitled the *Sākhīs*, *Sabds*, and *Rekhtas*, which have a wide popularity even among those who are not professed disciples of the saint. Several of the compositions enumerated under the name of Kabir are, however, not by him, but by his disciples: as the lesser *Bijak*, by Bhago-Dās, the *Sukh-Nidhān*, by Srut-Gopāl, &c.; it was the custom (as also that of Kabir's religious heirs, the Sikh Gurus) for the successors in the guruship to speak in the name of him whose successors they were. The doctrine of Kabir²

¹ This may be concluded from a short poem in the *Granth* (p. 469), where Kabir says (verses 4, 5):—"Let each one seek this Mind, O brother: when the body falls away, where shall the Mind be absorbed? By the favour of the Guru Jaideo and Nāmā through the love of Faith attained to knowledge of Him." (The *Mind* is the indwelling Rāma, *divinū particula aurā*.)

² A tolerably full account will be found in H. H. Wilson's *Essay on the Religious Sects of the Hindūs* (Works, vol. i. pp. 68 sqq.); Dr Trumpp's *Essay on the Religion of the Sikhs* (*Granth*, Introd., pp. xvii. sqq.) may also be consulted.

was philosophically a form of pantheism, accounting for the existence of phenomena (the reality of which was denied) by the agency of a *Māyā*, or illusion, emanating from the Supreme. The varied lot of men in life, their differences of faith and aim, their desires, fears, hopes, loves, are all the work of this *Māyā*, to know which, and to recognize beneath all the Supreme, is the only means of emancipation from the chains of illusion. Neither austerities, ritual, nor works of any kind are necessary to obtain the highest end; this is only to be gained by *bhakti*, "faith," and perpetual meditation on the Supreme—His names, *Hari*, *Rām*, *Govind*, being ever on the lips and in the heart. The highest end is absorption in the Supreme, reunion with Him from whom all proceeded and who exists in all. Little place is left in this somewhat barren doctrine for a social code, since works are naught; but negatively, at least, it is inoffensive, commanding respect for all forms of life, and quiet performance of duty without self-seeking or desire for gain.

Of the spiritual followers of Kabir many have left memorials in literature; one of the most eminent of these was Dādū, founder of a sect very prevalent in Rājputānā. A translation of two chapters from the *Granth* or scripture of this *Bhagat* will be found in a note to Wilson's *Religious Sects of the Hindus*, pp. 106–113, and will repay perusal. But those whose compositions, if not most excellent from a literary point of view, have at any rate wrought most in history, were the Gurus or spiritual heads of the Sikhs of the Panjāb. The *Ādi Granth*, or Book of the first five Gurus (from Nanak, who died in 1538, to Arjun, who died in 1601), is described by its translator as "perhaps the most shallow and empty book that exists, in proportion to its size;" and certainly the translation is not attractive reading. But the doctrines, reiterated with the most painful diffuseness, are essentially those of Kabir, much of whose writings has been incorporated in the volume. The language is rather Old Hindī than Old Panjābī, and thus the work falls within the scope of this article; though Panjābī words and idioms frequently occur, the grammar is Hindī; and the authors evidently aimed at propagating their tenets rather among the Hindī-speaking races of Hindostan proper than (as actually happened) among the Panjābī-speaking tribes of the West and South-West. The *Granth* consists of six parts: I., the *Japji*, the only portion as yet published in Europe in the original Hindī; II., III., and IV., arrangements for devotional purposes of extracts from Part V., the *Rāgs* or body of the *Granth*; of these *Rāgs* there are thirty-one, but only four, *Srī Rāg*, *Mājh*, *Gaurī*, and *Āsā*, have been rendered by Trumpp; the remaining twenty-seven are described as "a second gathering or gleaming, as materials offered themselves, no attention being paid to the contents, but only to the bulky size of the *Granth*;" VI., the *Bhog* or conclusion, containing verses by various authors, among them Kabir and Shekh Farid of Pakpaṭṭan, a famous Indian *Ṣūfī*, and panegyrics of the five Gurus by fifteen *bhaktis* or bards. At the end of each *Rāg* is a collection of sayings of the *Bhagats*, chiefly of Kabir, in confirmation of the doctrines set forth by the Gurus; and it is in these additions that the literary importance of the work, as a treasure of specimens of early Hindī, mainly consists.

Another of the following of Rāmānand, though considerably later in time than Kabir, was Sūr-Dās. Of his life little is known: as some of his verses are included in the *Granth*, he must have lived before its redaction (about 1600); if he be the same as a saint of that name mentioned in the *Bhaktamālā*, as is probable, he was a Brahman, *amīn* or revenue collector of the *parganah* of Sandilā in Oudh during the reign of Akbar, who is related to have appropriated the collections of his district for the service of the

temple of Madan-Mohan at Brindāban, sending to the treasury instead chests filled with stones. When his delinquency was discovered, he was pardoned by Akbar, but thenceforth abandoned the world, and, becoming blind, led a wandering life as a singer of the praises of Vishnu. His stanzas, generally of four lines (*padas*), are said to number no less than 125,000; they are collected in a huge volume entitled the *Sūr-Sūgar*, and are extremely popular.

While the sects of which Rāmānand may be considered the spiritual father adore the Deity chiefly under the names of *Rāma*, *Hari*, *Govind*, and dwell but little on the *avatārs* or human incarnations of the Hindu god whom they have selected as the type of the Supreme, there is another division of the Vaishnavas which is not less important in Hindī authorship, and counts its adherents by millions, whose worship is of a different character. The sects belonging to this division take Kṛishṇa as their favourite type of the godhead, and, accepting the whole mass of legends (most of them probably of comparatively late origin) relating to this incarnation, inspire themselves with fervour by the contemplation chiefly of Kṛishṇa's childhood and his youth in the society of the herd-maidens of Braj. As the doctrine and object of worship are, so also is the mode of life. The Rāmānandīs are for the most part men of ascetic and unworldly life, not indeed given to self-torture or needless rigour, but caring nothing for the wealth of the world, and living quietly and soberly in the possession of what they deem the truth. The worshippers of Kṛishṇa and his mistress Rādhā, or of the infant Bāl-Gopāl, on the other hand, are no ascetics, but persons of luxurious and often opulent lives; among women especially this form of devotion is widespread. The chief sect of this denomination is the *Vallabhāchārīs*, or the following of the *Gokulastha Gosāīs*. Their founder was one Vallabha Swāmī, a Brahman from the south, who settled at Gokul near Mathurā, probably about the beginning of the 16th century. The best known works of this sect are the *Braj-bilās*, a description of Kṛishṇa's sports with the maidens of Brindāban, by Brajbāsī-Dās, and the *Vārttā*, a collection of legends regarding eighty-four teachers of the following, resembling the *Bhaktamālā*, which deals chiefly with the other division of Vaishnavas. The popularity of the *Braj-bilās* is immense, and it is to be found in a lithographed form for sale in every bazaar. Its contents (as indeed many other productions of the worshippers of Kṛishṇa) have been condemned by Europeans as indecent; but although containing much that seems at least outwardly licentious and prurient, it is a work the study of which is indispensable to one who would understand the religious temper of the Hindus. The mystic dwelling on the amours of Kṛishṇa and the *Gopīs* of Braj has been often compared to the mystical interpretation of the *Song of Solomon*; and in most religions we shall perhaps find at least one phase in which the sensual is curiously mingled with the spiritual, and faith and love towards the heavenly stimulated by thoughts and phrases drawn from earthly scenes of passion. Of the *Vārttā* we shall speak under the next division of our subject.

2. Middle Hindī reaches from about 1570 to 1750. To this age belong the best poets of Hindī literature, Kesav-Dās, Bihārī-Lāl, and Tulsī-Dās, whose writings are no less remarkable for skill and subtlety of language than for perfection of metrical form. The labours of their predecessors had wrought the language of western Hindustan into a medium worthy of being put to the highest poetic use; and we accordingly find in the poets of this period large borrowings from Braj, even where (as with Tulsī-Dās) that idiom is not the dialect of their own region. From their day onward Braj-bhākhā has been esteemed (in the words of Lallū-Lāl) "the standard language of sentiment

(*mahārāsa-mūl*), and equal to the speech of the gods" (*i.e.*, Sanskrit).

Kesav-Dās was a Brahman who lived under Jahāngīr and Shāhjahān. He was the author of a poem on Rāma, entitled the *Rāmachandrikā*, written in 1602; the *Kavipriya*, written in the same year, a treatise on the poetic art of much celebrity; the *Rasik-priya*, on rhetoric, written in 1592; the *Bhaktā-tūlāmṛita*, an exposition of the doctrine of Rāmānandi Vaishnavism; and several other works. Kesav-Dās's compositions are widely popular, and have been frequently lithographed in Northern India.

Bihārī-Lāl is renowned as the author of the *Sat-sat*, a collection of 700 distichs, which is perhaps the most celebrated work of Hindī poetic art, as distinguished from narrative and simpler styles. They are inspired by the Kṛishṇa side of Vishṇu-worship; and take the form of amorous dialogues between Rādhā and the other *Gopīs* and their lover. The author was a native of Goāliyār, and lived at Amber during the early part of the 17th century. Editions of this work, one of the most difficult in Hindī and abounding in subtle conceits, are very numerous. It has been commented on by a crowd of scholars, among them, strange to say, more than one Musalmān,—a sufficient proof of the value set by natives of India, irrespective of their creed, on its perfection of language. It has even been translated into Sanskrit.

Tulsī-Dās, though perhaps inferior in poetic skill to the two last mentioned, is undoubtedly the most popular Hindī poet. His *Rāmāyan* (originally named by the author *Rām-charit-mānas*, or "the Lake of Rāma's deeds") is perhaps better known among Hindus in Upper India than the Bible among the rustic population of England. He was a Kanaujī Brahman, and probably (from his language) a native of Oudh. The greater part of his life he spent at Benares; he died in 1624. His *Rāmāyan* was commenced at Ayodhyā in 1573. Besides this great work, he is the author of six other poems, all bearing more or less on the history and worship of Rāma, called the *Rām-gītāvalī*, the *Dohāvalī*, the *Kābit-sambandh*, the *Bīnāy-patrikā*, the *Pad-Rāmāyan*, and the *Chhandāvalī*. Seven other minor works are attributed to him, but their authenticity is doubtful.

Tulsī's *Rāmāyan* is a rehandling of the great theme of Vālmikī, but in no sense a translation of the Sanskrit poem; real translations are scarcely to be found in original Hindī literature, the vernacular authors permitting themselves great liberty of excision, adaptation, and addition. It consists of seven books, of which the first two, called the *Bāl-kānd* and *Ayodhyā-kānd*, make up more than half the work, and relates the birth and boyhood of Rāma and his brethren, his marriage with Sītā, their dwelling together in the forest, her abduction by Rāvan, the expedition to Lankā and the overthrow of the ravisher, and the life at Ayodhyā after the return of the reunited pair. It is written chiefly in *dohās*, *sorathās*, and *chaupāīs*, with here and there a *chhand* interspersed; the style is very even and well sustained, and the language, while fundamentally the Old Pūrbī of eastern Hindustan, borrows largely from Braj. The most admired portion of the work is the second book, *Ayodhyā*, which tells of the mischief wrought by Kaikeyī, one of the queens of Dasarath, Rāma's father, who had bound himself by a vow to grant her what boon she should ask, and whom by this bond she compelled to command Rāma and Sītā to go into exile in the great forest south of the Jumna, and to give the throne to her own son Bharat. In this trouble Dasarath dies, and his son obediently goes forth with his wife and his brother Lachhman to the southern wilderness. The sorrow of Dasarath, the sweet filial piety and perfect manhood of the divine Rāma, the valour and prompt affection of Lachhman, the sincerity and humility of Bharat, the purity and wifely obedience of Sītā, are

themes which a Hindu reader is never tired of dwelling upon in Tulsī's pages. And unlike though the treatment be to our own standards of taste, overgrown with theological digressions and explanations, and stocked with conventional images and stereotyped phrases as the poem is, even a European may find in it something of literary achievement which appeals to him, however distantly, as the work of a master of the heart. The first two books of the *Rāmāyan* have been admirably rendered into English prose by Mr F. S. Growse (Allahabad, 1877-78).

Tulsī, though essentially a Hindu and a Brahman in religious feeling, yet belongs to the class of Vaishnavas who count among them Rāmānand and Kabir. He has little or nothing of the sensual passion of the devotees of Kṛishṇa and Rādhā; and in the commentary on the *Bhaktamālā* it is related that, when in his old age he paid a visit to Brindāban, the centre of the Kṛishṇa-cult, he refused to render homage to any other form of the god than Rāma. According to the legend, he was beguiled into a temple of Kṛishṇa, and bidden there to worship Rāma; he answered that he would only bow his head before one who should bear in his hand the bow and arrows of the king of Ayodhyā; hearing his speech, the image of the god, standing till then as Kṛishṇa with the flute (*Dansīdhar*), suddenly changed to the similitude of Rāma with the bow.

The *Bhaktamālā*, or "Roll of the *Bhagats*," is a celebrated work of this period, and is ascribed to Nābhājī, a Vaishnava of the despised caste called *Doms* or *Domvās*, who lived during the reign of Jahāngīr, and was a contemporary of Tulsī-Dās. The *Bhaktamālā*, in the form in which it is commonly met with, consists of a *mūl*, or original text, ascribed to Nābhājī, and a *ṭikā*, or commentary, of which there are two, due respectively to Kṛishṇa-Dās and Priya-Dās, both stated to have been written in 1713, in verse, and many more in prose. The *mūl* is a short stanza (*chhappai*) for each saint, the first line of which is repeated again at the end, stating, in the briefest and most obscure language, his characteristics. The original work of Nābhājī was amplified and added to by Nārāyan-Dās, who lived during the reign of Shāhjahān. Mr Growse justly says of it:—"The style (of the *mūl*) might be described as of unparalleled obscurity, were it not that each separate portion of the text is followed by a *ṭikā*, or gloss, in which confusion is still worse confounded by a series of the most disjointed and inexplicit allusions to different legendary events in the saint's life." A considerable portion of the *Bhaktamālā* was printed in 1817 in Major Price's *Hindī and Hindustani Selections*, and it has been largely drawn upon by Wilson in his account of the religious sects of the Hindus. The saints treated in it are chiefly of the class of Vaishnavas addicted to the worship of Rāma; and the anecdotes of them contained in the work are generally insipid and extravagant in the extreme. "Such as it is, however, it exercises a powerful influence in Upper India on popular belief, and holds a similar place in the superstitions of this country to that which was occupied, in the darkest ages of the Roman Catholic faith, by the *Golden Legend and Acts of the Saints*" (Wilson).

The other side of Vaishnavism, that devoted to the cult of the infant or youthful Kṛishṇa, with or without his mistress Rādhā, is represented by a work similar in character to the *Bhaktamālā*, called the *Vārttā*, or *Chaurāsī Vārttā*, already mentioned. Specimens of its contents will be found in Wilson's *Religious Sects of the Hindus*, p. 132. Its legends are of the most trivial and childish description; but, with the tenth chapter of the *Bhāgavata Purāna*, rendered into Braj-bbākhā by Chaturbhuj Miśr, and into modern Hindī in 1804-10 by Lallū Lāl, they are nevertheless the inspirers of the greater part of the popular worship throughout the whole of Northern India. The universality

of the cult of the infant Krishna may be judged by the enormous number of Hindu proper names which end in *Lāl*, meaning "child," all of which embody some reference to this deity in his youthful form. In Bengal especially the sect is extremely numerous, having there arisen out of the teaching of Chaitanya, who is said to have married a daughter of Vallabhāchārya, and is believed by his followers to have been himself an incarnation of Krishna.

Such, in the briefest outline, is the character of Hindi literature during the period when it grew and flourished through its own original forces. Founded by a popular impulse in many respects similar to that which gave rise to Buddhism nearly 2000 years before, and cultivated chiefly (though by no means exclusively) by authors not belonging to the Brahmanical order, it was the legitimate descendant in spirit, as Hindi is the legitimate descendant in speech, of the Prākṛit literature which preceded it. Entirely in verse, it adopted and elaborated the Prākṛit metrical forms, and carried them to a pitch of perfection which is too often overlooked by those who concern themselves rather with the substance than with the form of the works they study. The language of these compositions strikes us often as rude, abrupt, and ambiguous; undoubtedly in its earlier specimens it is wanting in clearness and definiteness of grammatical form; but the shackles of metre are frequently the explanation of uncouth forms of speech, and the necessity of filling out a metrical scheme led in too many cases to irregularities and amplifications which had perhaps no representatives in the uncompelled utterances of the vernacular tongue. Interesting when regarded in the mass, its attractions in detail are few. As in all Oriental literature, repetition and shallowness of idea overcome it, and render an extensive course of reading intolerable to a European. Conventional images, platitudes exhausted to the utmost degree of tenuity, barren philosophical and theological themes which in their wideness entirely overlook the study of detail,—such are, with few exceptions, its leading features; and one who has read two or three books has in truth made himself master of the whole secret of original Hindi literature.

3. The *origines* of Urdū as a literary language are extremely obscure. The popular account refers its rise to the time of Timūr (1398). Some authors even claim for it a higher antiquity, asserting that a *divān*, or collection of poems, was composed in *Rekhtah* by Mas'ūd, son of Sa'd, in the last half of the 11th and beginning of the 12th century, and that Sa'dī of Shirāz and his friend Amīr Khusrāu of Dehli likewise made verses in that dialect before the end of the 13th century. This, however, is very questionable; and the better opinion appears to be that these ancient compositions, if they existed at all, were written in Hindi according to the metrical forms of that language, rather than in what is properly called Urdū. That Muhammadans composed in Hindi, and used that language as their vernacular, is certain; and in many passages of Kabīr, which are nevertheless pure Hindi compositions, Persian words are used almost as freely as in the modern dialect. Much of the confusion which besets the subject is due to the want of a clear definition of what Urdū, as opposed to Hindi, really is.

Urdū, as a literary language, differs from Hindi rather in its form than in its substance. The really vital point of difference, that in which Hindi and Urdū are incommensurable, is the prosody. Hardly one of the metres taken over by Urdū poets from Persian agrees with those used in Hindi; in the latter language, it is the rule to give the short *a* inherent in every consonant or group of consonants its full value in scansion, except occasionally at the metrical pause: in Urdū this is never done, the only somewhat analogous rule providing for the enunciation of a short *a*

(the *nīm-fathah*) after a nexus of consonants which would otherwise be pronounced without it; the great majority of Hindi metres are counted by the number of syllabic instants or *mātrās* (the value in time of a short syllable): in Urdū the metres follow a special order of longs and shorts.

The question, then, is not—When did Persian first become intermixed with Hindi in the literary speech?—for this process began with the first entry of Muslim conquerors into India, and continued for centuries before a line of Urdū was composed;—nor, When was the Persian character first employed to write Hindi?—for the written form is but a subordinate matter. We must ask—When was the first verse composed in Hindi, whether with or without foreign admixture, according to the forms of Persian prosody and not in those of the indigenous metrical system? Then, and not till then, did Urdū come into being. If, then, it is really the case that poems were so composed as early as the 11th or the 13th century, the origin of Urdū literature must be carried back to that period. But Hindi itself was at that date, and for many decades later (as we see from Chand and our other earliest specimens of the language), in an unsettled and transition stage. Neither in its case-inflections nor in its verbal forms did it resemble the language which we know as Urdū. It abounded in short vowels and hiatuses, which could not accommodate themselves either to the Persian character (without the free use of vowel-signs and *hamzah*, which were seldom employed) or to Persian prosody; and its syntactical order was loose and unsettled. Urdū, as we know it, is the Hindi of the end of the 16th century enriched from Persian, not the Hindi of Chand and the early *Bhagats*.

The whole of Urdū poetry follows Persian models or composition; its themes are those which had already been worked (some might say, worked out) by writers in that language; and neither in form nor substance do we find the faintest flavour of originality from its commencement to the present day.

The paucity of themes and want of originality in Urdū verse has led to a most elaborate development of the system of rhetoric. Where the substance of what a poet has to say is identical with that which has been said by hundreds, nay thousands, of poets before him, it is of the highest importance that the way of saying it shall if possible be peculiar to himself. Rhetoric, accordingly, rather than poetic feeling, is the distinguishing feature of composition in Urdū. Pleasing hyperbole, ingenious comparison, antithesis, alliteration, carefully arranged gradation of noun and epithet, are the means employed to obtain variety; and few of the most eloquent passages of Urdū verse admit of translation into any other language without losing that which in the original makes their whole charm. Even in the *masnavīs*, or narrative poems, the story is usually quite a subordinate matter; it has in most cases been handled time after time, and is familiar to the reader in its minutest detail. Even when the names chosen for the actors are new, the intrigue is old, and the mode in which it is unfolded is the only thing which distinguishes one poem from another. The descriptions thus, confined within a narrow circle of incident and epithet, repeat each other with a monotony which to a European is inexpressibly fatiguing, but which in the East is deemed rather a merit than a defect. Differences of school, which are made much of by native critics, are to us hardly perceptible; they consist in the use of one or other range of metaphor and comparison, classed, according as they repeat the well-worn poetical stock-in-trade of the Persians or seek a slightly fresher and more Indian field of sentiment, as the old or the new style of composition.

These being the nature and features of Urdū poetry, it will be manifest that such an account of it as c

be given here must be little more than a list of names and dates.¹

The earliest Urdū authors lived and wrote in the Dakkhan, at the courts and under the patronage of the Muhammadan dynasties of Golkonda and Bijāpur, shortly before these dynasties were overthrown by the campaigns of Aurangzeb in the south. Shujā'uddin Nūrī, a native of Gujarāt, a friend of Faizi and contemporary of Akbar, is mentioned by the native biographers as the most ancient Urdū poet after Amīr Khusrāu. He was tutor of the son of the *vazīr* of Sultān Abu-l-Hasan Qutb Shāh of Golkonda, and several *ghazals* by him are said to survive. Qulī Qutb Shāh of Golkonda, who reigned from 1581 to 1586, and his successor 'Abdullāh Qutb Shāh, who came to the throne in 1611, have both left collections of verse, including *ghazals*, *rubā'īs*, *masnavīs* and *qaṣīdahs*. And during the reign of the latter Ibn Nishā'ī wrote two works which are still famous as models of composition in Dakkhi; they are *masnavīs* entitled the *Tūfi-nāmah*, or "Tales of a Parrot," and the *Phūl-ban*. The first, written in 1639, is an adaptation of a Persian work by Nakhsabī, but derives ultimately from a Sanskrit original entitled the *Suka-saptati*; this collection has been frequently rehandled in Urdū, both in verse and prose, and is the original of the *Toṭā-Kahānī*, one of the first works in Urdū prose, composed in 1801 by Muhammad Haidar-bakhsh Haidarī of the Fort William College. The *Phūl-ban* is a love tale named from its heroine, said to be translated from a Persian work entitled the *Basātin*. Another famous work which probably belongs to the same place and time is the *Story of Kām-rūp and Kalā* by Tahsinuddīn, a *masnavī* which has been published (1836) by M. Garcin de Tassy; what makes this poem remarkable is that, though the work of a Musalmān, its personages are Hindū. Kām-rūp, the hero, is son of the king of Oudh, and the heroine, Kalā, daughter of the king of Ceylon; the incidents somewhat resemble those of the tale of es-Sindibād in the *Thousand and One Nights*; the hero and heroine dream one of the other, and the former sets forth to find his beloved; his wanderings take him to many strange countries and through many wonderful adventures, ending in a happy marriage.

The court of Bijāpur was no less distinguished in literature. Ibrahim 'Adil Shāh (1579-1626) was the author of a work in verse on music entitled the *Nau-ras* or, "Nine Savours," which, however, appears to have been in Hindi rather than Urdū; the three prefaces (*dirājahs*) to this poem were rendered into Persian prose by Maulā Zuhūrī, and, under the name of the *Sih nasr-i Zuhūrī*, are well-known models of style. A successor of this prince, 'Alī 'Adil Shāh, had as his court poet a Brahman known poetically as Nusrati, who in 1657 composed a *masnavī* of some repute entitled the *Gulshan-i 'Ishq*, or "Rose-garden of Love," a romance relating the history of Prince Manohar and Madmalatī,—like the *Kām-rūp*, an Indian theme. The same poet is author of an extremely long *masnavī* entitled the *'Alī-nāmah*, celebrating the monarch under whom he lived.

These early authors, however, were but pioneers and feelers of the way; the first generally accepted standard of form, a standard which has suffered little change in two centuries, was established by Wali of Aurangābād (about 1680-1720) and his contemporary and fellow-townsmen Sirāj. The former of these is commonly called "the Father of Rekhtah"—*Bābā-e Rekhtah*; and all accounts agree that the immense development attained by Urdū poetry in Northern India during the 18th century was due to his example and initiative. Very little is known of Wali's life; he is believed to have visited Dehli towards the end of the reign of Aurangzeb, and is said to have there received instruction from Shāh Gulshan in the art of clothing in a vernacular dress the ideas of the Persian poets. His *Kulliyāt* or complete works have been published by M. Garcin de Tassy, with notes and a translation of selected passages (Paris, 1834-36), and may be commended to readers desirous of consulting in the original a favourable specimen of Urdū poetical composition.

The first of the Dehli school of poets was Zuhūriddin Hātim, who was born in 1699 and died in 1792. In the second year of Muhammad Shāh (1719), the *divān* of Wali reached Dehli, and excited the emulation of scholars there. Hātim was the first to imitate it in the Urdū of the north, and was followed by his friends Nāji, Mazmūn, and Abrū. Two *divāns* by him survive. He became the founder of a school, and one of his pupils was Rafi'us-Saudā, the most distinguished poet of Northern India. Khān Arzū (1689-1756) was another of the fathers of Urdū poetry in the north. This author is chiefly renowned as a Persian scholar, in which language he not only composed much poetry, but one of the best of Persian lexicons, the *Sirāj-ul-lughāt*; but his compositions in Urdū are also highly esteemed. He was the master of Mir Taqī, who

stands next to Saudā as the most eminent Urdū poet. Arzū died at Lakhnau (Lucknow), whither he betook himself after the devastation of Dehli by Nādir Shāh (1739). Another of the early Dehli poets who is considered to have surpassed his fellows was In'āmullāh Khān Yaqīn, who died during the reign of Ahmad Shāh (1748-54), aged only twenty-five. Another was Mir Dard, pupil of the same Shāh Gulshan who is said to have instructed Wali; his *divān* is not long, but extremely popular, and especially esteemed for the skill with which it develops the themes of spiritualism. In his old age he became a *darwesh* of the *Naqshbandī* following, and died in 1793.

Saudā and Mir Taqī are beyond question the most distinguished Urdū poets. The former was born at Dehli about the beginning of the 18th century, and studied under Hātim. He left Dehli after its devastation, and settled at Lakhnau, where the Nawāb Asafuddaulah gave him a *jāgir* of Ra. 6000 a year, and where he died in 1780. His poems are very numerous, and cover all the styles of Urdū poetry; but it is to his satires that his fame is chiefly due, and in these he is considered to have surpassed all other Indian poets. Mir Taqī was born at Agra, but early removed to Dehli, where he studied under Arzū; he was still living there at the time of Saudā's death, but in 1782 repaired to Lakhnau, where he likewise received a pension; he died at a very advanced age in 1810. His works are very voluminous, including no less than six *divāns*. Mir is counted the superior of Saudā in the *ghazal* and *masnavī*, while the latter excelled him in the satire and *qaṣīdah*. Sayyid Ahmad, an excellent contemporary authority, and himself one of the best of modern authors in Urdū, says of him in his *Asāru-s-Sanā'id*:—"Mir's language is so pure, and the expressions which he employs so suitable and natural, that to this day all are unanimous in his praise. Although the language of Saudā is also excellent, and he is superior to Mir in the point of his allusions, he is nevertheless inferior to him in style."

The tremendous misfortunes which befell Dehli at the hands of Nādir Shāh (1739), Ahmad Shāh Durrānī (1756), and the Marāthās (1759), and the rapid decay of the Mughal empire under these repeated shocks, transferred the centre of the cultivation of literature from that city to Lakhnau, the capital of the newly founded and flourishing state of Oudh. It has been mentioned how Arzū, Saudā, and Mir betook themselves to this refuge and ended their days there; they were followed in their new residence by a school of poets hardly inferior to those who had made Dehli illustrious in the first half of the century. Here they were joined by Mir Hasan (died 1786), Mir Soz (died 1800), and Qalandar-bakhsh Jur'at (died 1810), also like themselves refugees from Dehli, and illustrious poets. Mir Hasan was a friend and collaborator of Mir Dard, and first established himself at Faizābād and subsequently at Lakhnau; he excelled in the *ghazal*, *rubā'ī*, *masnavī*, and *marsiyyah*, and is counted the third, with Saudā and Mir Taqī, among the most eminent of Urdū poets. His fame chiefly rests upon a much admired *masnavī* entitled the *Sihru-l-bayān*, or "Magic of Eloquence," a romance relating the loves of Prince Be-nazir and the Princess Badr-i Munir; his *masnavī* called the *Gulzar-i 'Iram* ("Rose-garden of Iram," the legendary 'Adite paradise in Southern Arabia), in praise of Faizābād, is likewise highly esteemed. Mir Muhammadī Soz was an elegant poet, remarkable for the success with which he composed in the dialect of the harem called *Rekhtī*, but somewhat licentious in his verse; he became a *darwesh* and renounced the world in his later years. Jur'at was also a prolific poet, but, like Soz, his *ghazals* and *masnavīs* are licentious and full of double meanings. He imitated Saudā in satire with much success; he also cultivated Hindi poetry, and composed *dohrās* and *kabitts*. Miskin was another Lakhnau poet of the same period, whose *marsiyyahs* are especially admired; one of them, that on the death of Muslim and his two sons, is considered a masterpiece of this style of composition. The school of Lakhnau, so founded and maintained during the early years of the century, continued to flourish till the dethronement of the last king, Wājid 'Alī, in 1856. Atash and Nāsikh (who died respectively in 1847 and 1841) are the best among the modern poets of the school in the *ghazal*; Mir Anis, a grandson of Mir Hasan, and his contemporary Dabir, the former of whom died in December 1875 and the latter a few months later, excelled in the *marsiyyah*. Rajab Ali Beg Surūr, who died in 1869, was the author of a much-admired romance in rhyming prose entitled the *Fasānah-e 'Ajāib* or "Tale of Marvels," besides a *divān*. The dethroned prince Wājid 'Alī himself, poetically styled Akhtar, is no mean poet; he has published three *divāns*, among them a quantity of poetry in the rustic dialect of Oudh which is philologically of much interest.

Though Dehli was thus deserted by its brightest lights of literature, it did not altogether cease to cultivate the poetic art. Among the last Mughals several princes were themselves creditable poets. Shāh 'Alam II. (1761-1806) wrote under the name of Aftāb, and was the author of a romance entitled *Mazmūn-i Aqdās*, besides a *divān*. His son Sulaimān-shikoh, brother of Akbar Shāh II., who had at first, like his brother authors, repaired to Lakhnau, returned to Dehli in 1815, and died in 1838; he also has left a *divān*. Lastly, his nephew Bahādūr Shāh II., the last titular emperor of

¹ The late M. Garcin de Tassy's *Histoire de la Littérature Hindoue et Hindoustanie*, and his annual summaries of the progress made from 1850 to 1877, afford all the materials which can be desired on this subject by one who does not care to refer to the original vernacular works; the peculiarities of the latter can be learned only from long-continued study and familiarity with Oriental modes of thought.

Dehli (died 1862), wrote under the name of Zafar, and was a pupil in poetry of Shaikh Ibrāhīm Zauq, a distinguished writer; he has left a voluminous *diwān*, which has been printed at Dehli. Mashafi (Ghulam-i Hamdani), who died about 1814, was one of the most distinguished of the revived poetic school of Dehli, and was himself one of its founders. Originally of Lakhnau, he left that city for Dehli in 1777, and held conferences of poets, at which several authors who afterwards acquired repute formed their style; he has left five *diwāns*, a *Tazkirah* or biography of Urdū poets, and a *Shāh-nāmah* or account of the kings of Dehli down to Shāh 'Alam. Qāim (Qiyāmuddin 'Ali) was one of his society, and died in 1792; he has left several works of merit. Ghālīb, otherwise Mirzā Asadullāh Khān Nausahāb, laureate of the last Mughal, who died in 1869, is undoubtedly the most eminent of the modern Dehli poets. He wrote chiefly in Persian, of which language, especially in the form cultivated by Firdausi, free from intermixture of Arabic words, he was a master; but his Urdū *diwān*, though short, is excellent in its way, and his reputation was spread far and wide. To this school, though he lived and died at Agra, may be attached Mir Wali Muhammad Nazir (recently dead in 1832); his *masnavis* entitled *Jogi-nāmah*, *Kauri-nāmah*, *Banjāre-nāmah*, and *Burhāpore-nāmah*, as well as his *diwān*, have been frequently reprinted, and are extremely popular. His language is less artificial than that of the generality of Urdū poets, and some of his poems have been printed in Nāgarī, and are as well known and as much esteemed by Hindus as by Muhammadans.

4. While such, in outline, is the history of the poetic schools of the Dakkhan, Dehli, and Lakhnau, a fourth, that of the Fort William College at Calcutta, was being formed, and was destined to give no less an impulse to the cultivation of Urdū prose than had a hundred years before been given to that of poetry by Wali. At the commencement of the present century Dr John Gilchrist was the head of this institution, and his efforts were directed towards getting together a body of literature suitable as text-books for the study of the Urdū language by the European officers of the administration. To his exertions we owe the elaboration of the vernacular as an official speech, and the possibility of substituting it for the previously current Persian as the language of the courts and the government. He gathered together at Calcutta the most eminent vernacular scholars of the time, and their works, due to his initiative, are still unsurpassed as specimens of elegant and serviceable prose composition, not only in Urdū, but also in Hindī. The chief authors of this school are Haidarī (Sayyid Muhammad Haidar-bakhs), Husainī (Mir Bahādur 'Ali), Mir Amman Lutf, Hafizuddin Ahmad, Sber 'Ali Afsos, Nihal Chand of Lahore, Kāzim 'Ali Jawān, Lallū Lāl Kavi, Mazhar 'Ali Wilā, and Ikrām 'Ali.

Haidarī died in 1828. He composed the *Toḡā-Kahānī* (1801), a prose redaction of the *Tuḡi-nāmah* which has been already mentioned; a romance named *Arāish-i Mahfil* ("Ornament of the Assembly"), detailing the adventures of the famous Arab chief Ibtīm-i Ḥai; the *Gul-i Maghfirat* or *Dah Majlis*, an account of the holy persons of the Muhammadan faith; the *Gulzār-i Dānish*, a translation of the *Bahār-i Dānish*, a Persian work containing stories descriptive of the craft and faithlessness of women; and the *Tārikh-i Nādirī*, a translation of a Persian history of Nādir Shāh. Husainī is the author of an imitation in prose of Mir Hasan's *Sihru-l-bayān*, under the name of *Nasr-i Benazir* ("the Incomparable Prose," or "the Prose of Benazir," the latter being the name of the hero), and of a work named *Akhlaq-i Hindī*, or "Indian Morals," both composed in 1802. The *Akhlaq-i Hindī* is an adaptation of a Persian work called the *Mufarriḥu-l-qulūb* ("the Delighter of Hearts"), itself a version of the *Hilopadesa*. Mir Amman was a native of Dehli, which he left in the time of Ahmad Shāh Durrāni for Patna, and in 1801 repaired to Calcutta. To him we owe the *Bāgh o Bahār* (1801-2), an adaptation of Amīr Khusrau's famous Persian romance entitled the *Chahār Darvesh*, or "Story of the Four Dervishes." Amman's work is not itself directly modelled on the Persian, but is a rehandling of an almost contemporary rendering by Tahsin of Etāwā, called the *Nau-tarzi Murassa*. The style of this composition is much admired by natives of India, and editions of it are very numerous. Amman also composed an imitation of Husain Wāiz Kāshif's *Akhlaq-i Muhsini* under the name of the *Ganj-i Khūbi* ("Treasure of Virtue"), produced in 1802. Hafizuddin Ahmad was a professor at the Fort William College; in 1803 he completed a translation of Abu-l-Fazl's *Iyār-i Dānish*, under the name of the *Khīrad-afroz* ("Enlightener of the Understanding"). The *Iyār-i Dānish* ("Touchstone of Wisdom") is one of the numerous imitations of the

originally Sanskrit collection of apologues known in Persian as the *Fables of Bidpai*, or *Kalīlah and Damnah*. Afsos was one of the most illustrious of the Fort William school; originally of Dehli, he left that city at the age of eleven, and entered the service of Qāsim 'Ali Khān, Nawāb of Bengal; he afterwards repaired to Haiderābād in the Dakkhan, and thence to Lakhnau, where he was the pupil of Mir Hasan, Mir Soz, and Mir Haidar 'Ali Hairān. He joined the Fort William College in 1800, and died in 1809. He is the author of a much esteemed *diwān*; but his chief reputation is founded on two prose works of great excellence, the *Avāish-i Mahfil* (1805), an account of India adapted from the introduction of the Persian *Khulāṣatu-l-tawārikh* of Sujān Rāc, and the *Bāgh-i Urdū* (1808), a translation of Sūdī's *Gulistān*. Nihal Chand translator into Urdū a *masnavi*, entitled the *Gul-i Bakāwālī*, under the name of *Mazhab-i Ishq* ("Religion of Love"); this work is in prose intermingled with verse, was composed in 1804, and has been frequently reproduced. Jawān, like most of his collaborators, was originally of Dehli and afterwards of Lakhnau; he joined the College in 1800. He is the author of a version in Urdū of the well-known story of Sakuntalā, under the name of *Sakuntalā Nāṭak*; the Urdū was rendered from a previous Braj-bhākhā version by Nawāz Kabīshwar made in 1716, and was printed in 1802. He also composed a *Bārah-māsā*, or poetical description of the twelve months (a very popular and often-handled form of composition), with accounts of the various Hindu and Muhammadan festivals, entitled the *Dastūr-i Hind* ("Usages of India"), printed in 1812. Ikrām 'Ali translated, under the name of the *Ikhvānu-s-safā*, or "Brothers of Purity" (1810), a chapter of a famous Arabian collection of treatises on science and philosophy entitled *Rasālu Ikhvāni-s-safā*, and composed in the 10th century. The complete collection, due to different writers who dwelt at Basrah, has recently been made known to European readers by the translation of Dr F. Dieterici (1858-1879); the chapter selected by Ikrām 'Ali is the third, which records an allegorical strife for the mastery between men and animals before the king of the *Jinn*. The translation is written in excellent Urdū, and is one of the best of the Fort William productions.

Sri Lallū Lāl was a Brahman, whose family, originally of Gujārat, had long been settled in Northern India. What was done by the other Fort William authors for Urdū prose was done by Lallū Lāl almost alone for Hindī. His *Prem Sāgar* and *Rājnīti*, the former a version in pure Hindī of the 10th chapter of the *Bhāgavata Purāna*, detailing the history of Kṛishṇa, and founded on a previous Braj-bhākhā version by Chaturbhuj Misr, and the latter an adaptation in Braj-bhākhā prose of the *Hilopadesa* and part of the *Pancha-lantra*, are unquestionably the most important works in Hindī prose. The *Prem Sāgar* was begun in 1804 and ended in 1810; it enjoys immense popularity in Northern India, has been frequently reproduced in a lithographed form, and has several times been printed. The *Rājnīti* was composed in 1809; it is much admired for its sententious brevity and the purity of its language. Besides these two works, Lallū Lāl was the author of a collection of a hundred anecdotes in Hindī and Urdū entitled *Loḡāif-i Hindī*, an anthology of Hindī verse called the *Sabhā-bīlās*, a *Sal-sai* in the style of Bihārī-Lāl called *Sapta-Satīka*, and several other works. He and Jawān worked together at the *Singhāsān Battisi* (1801), a redaction in mixed Urdū and Hindī (Devanāgarī character) of a famous collection of legends relating the prowess of King Vikramāditya; and he also aided the latter author in the production of the *Sakuntalā Nāṭak*. Mazhar 'Ali Wilā was his collaborator in the *Baitāl Pachisi*, a collection of stories similar in many respects to the *Singhāsān Battisi*, and also in mixed Urdū-Hindī; and he aided Wilā in the preparation in Urdū of the *Story of Mādhūnāl*, a romance originally composed in Braj-bhākhā by Motī Rām.

The works of these authors, though compiled and published under the superintendence of Dr Gilchrist, Captain Abraham Lockett, Professor J. W. Taylor, Dr W. Hunter, and other European officers of the College, are essentially Indian in taste and style, and owe to this character a popularity and wide reputation which have been gained by no other work (and there have been many) undertaken under British initiative. If not absolutely the first works in Urdū and Hindī prose, they were at any rate the first literary standards in those languages; and almost the whole of recent prose authorship is due either to their influence or to one of two other impulses, the first of which was almost synchronous with the Fort William productions, and the other not many years posterior to them. These were the reform in Islām led by Sayyid Ahmad, and the introduction of lithography and a newspaper press.

Sayyid Ahmad was born in 1782, and received his early education at Dehli; his instructors were two learned Muslims, Shāh 'Abdu-l-'Aziz, author of a celebrated commentary on the Qur'ān (the *Tafsir-i 'Aziziyah*), and his brother 'Abdu-l-Qādir, the writer of the first and best translation of the Holy Volume into Urdū. Under their guidance Sayyid Ahmad embraced the doctrines of the Wahhābīs, a sect whose preaching appears at this time to have first reached India. He gathered round him a large number of fervent disciples, among others Ismūll Hāji, nephew of 'Abdu-l-'Aziz and

Abdu-l-Qādir, the chief author of the sect. After a course of preaching and apostleship at Dehli, Sayyid Ahmad set out in 1820 for Calcutta, attended by numerous adherents. Thence in 1822 he started on a pilgrimage to Mecca, whence he went to Constantinople, and was there received with distinction and gained many disciples. He travelled for nearly six years in Turkey and Arabia, and then returned to Dehli. The religious degradation and coldness which he found in his native country strongly impressed him after his sojourn in lands where the life of Islām is stronger, and he and his disciples established a propaganda throughout Northern India, reproaching the superstitions which had crept into the faith from contact with Hindus, and preaching a *jihād* or holy war against the Sikhs. In 1828 he started for Peshāwar, attended by, it is said, upwards of 100,000 Indians, and accompanied by his chief followers, Hāji Ismā'il and 'Abdu-l-Hayy. He was furnished with means by a general subscription in Northern India, and by several Muhammadan princes who had embraced his doctrines. At the beginning of 1829 he declared war against the Sikhs, and in the course of time made himself master of Peshāwar. The Afghāns, however, with whom he had allied himself in the contest, were soon disgusted by the rigour of his creed, and deserted him and his cause. He fled across the Indus and took refuge in the mountains of Pakhli and Dhamtor, where in 1831 he encountered a detachment of Sikhs under the command of Sher Singh, and in the combat he and Hāji Ismā'il were slain. His sect is, however, by no means extinct; the Wahhābi doctrines have continued to gain ground in India, and to give rise to much controversial writing, down to our own day.

The translation of the Qur'an by 'Abdu-l-Qādir was finished in 1803, and first published by Sayyid 'Abdullāh, a fervent disciple of Sayyid Ahmad, at Hūghli in 1829. The *Tambihu-l-ghāfilin*, or "Awakener of the Heedless," a work in Persian by Sayyid Ahmad, was rendered into Urdū by 'Abdullāh, and published at the same press in 1830. Hāji Ismā'il was the author of a treatise in Urdū entitled *Taqwiyatu-l-Imān* ("Confirmation of the Faith"), which had great vogue among the following of the Sayyid. Other works by the disciples of the *Tarīqah-i-Muhammadiyah* (as the new preaching was called) are the *Targhib-i-Jihād* ("Incitation to Holy War"), *Hidāyatu-l-Muminin* ("Guide of the Believers"), *Muzihul-Kabāir wa-l-Bid'ah* ("Exposition of Mortal Sins and Heresy"), *Nasihat-u-Muslīn* ("Admonition to Muslims"), and the *Kitāb Masā'il*, or "Hundred Questions."

Printing was first used for vernacular works by the College Press at Fort William, and all the compositions prepared for Dr Gilchrist and his successors which have been already mentioned were thus made public; but the expense of this method of reproduction long precluded its extensive use in India, and the ungraceful characters used as types were not appreciated by the natives. In 1837 the first lithographic press was set up at Dehli, and from that date onwards the publications, original or editions of older works, issued in this shape annually may be counted by hundreds. The newspaper press soon followed the introduction of lithography, and there are at present about two hundred journals in Urdū and Hindi printed in India, the majority in the North-Western Provinces, the Panjāb, and Oudh, but a few at Madras, Haidarābād, Bangalore, Bombay, and Calcutta. The extension taken by vernacular literature during the last thirty years is enormous, and to describe it adequately would require a volume. The reader is referred for the best account of it to M. Garcin de Tassy's *Annual Summaries* from 1850 to 1877, where he will also find much interesting information regarding the nature and value of the newspapers now so numerous. Here a few names only can be mentioned which seem the most prominent among the crowd of writers who daily, by the cheap and simple agency of a lithographic stone and bāzār paper, make their ideas public in Northern India.

Sayyid Ahmad Khān Bahādur, C.S.I. (not to be confounded with the Wahhābi reformer), is perhaps the most eminent and eloquent among contemporary writers of Urdū. He is the author of numerous works, among others of the *Asāru-s-Sanā'id* ("Vestiges of Princes"), an excellent account of Dehli and its monuments, which has passed through three editions (1847, 1854, 1876). His fame, however, chiefly rests upon his persevering efforts to raise the standard of civilization and culture among his co-religionists, for which purpose he has since 1870 issued a most valuable journal entitled the *Tahzibu-l-Akhlag*, or "Muhammadan Social Reformer" (which, unlike almost all its competitors, is printed with movable types). The articles in this publication, chiefly of a religious or educational character, are of a high order of excellence, and display most effectively the resources of the Urdū language as a means of expressing modern ideas. Maulavi Nazir Ahmad of Dehli is the author of two excellent stories named *Mir'ātu-l-'arūs* ("the Bride's Mirror") and *Tnubatu-n-Nasūh* ("the Repentance of Nasūh"); and Pandit Kāshināth of Agra has written a good treatise on ethics, founded on Persian compilations on the subject, called *Akhlag-i-Kāshī*. These three works have received rewards from the Government of the North-Western Provinces, and enjoy much popularity. The officers of the educational department have been prolific in

schoolbooks of various degrees of excellence. Mr H. S. Reid and his assistants, Qamaruddīn Gulāb Khān, Chiranjī Lāl, Pandit Bansīdhar, Sū Lāl, and Mohan Lāl, were at work from 1851 to 1860 in this direction, and several good translations and compilations are due to them. In the Panjāb Zūkānūllāh Khān of Dehli, and Karimuddin and Pandit Ajodhiyā Parshād of Lahore, have been no less active; and Northern India is now well supplied with the means of elementary education in the vernacular in literature, history, geography, and mathematics. Science, owing to the difficulties of technical nomenclature, is less efficiently represented, and the controversy regarding the best method of clothing its vocabulary in a vernacular dress is hardly yet solved. Owing to the fortunate circumstance that Urdū is able to draw for its vocabulary upon Persian and Arabic as well as upon its native Indian resources, the attempts which have been made in Egypt, Turkey, and other countries where these languages are in use to provide vernacular equivalents for scientific terminology will, it may be hoped, work not only for the benefit of those countries, but also for that of India, and thus in time provide a satisfactory means of raising vernacular education in science to the level of other branches of culture.

In Hindi also there is much activity, though not so much as in Urdū. The pure or "High" Hindi, which rejects all foreign words, and supplies its vocabulary exclusively from Sanskrit, is a recent creation, and cannot even yet be said to represent the language of any large class of the population. A good specimen of this dialect is Nilkānth Shāstrī Gore's *Shad-Darshan Darpan*, or "Mirror of the Six (orthodox) Schools (of Hindu philosophy)," a controversial work by a converted Brahman. The genuine Hindi of the old literature, used now exclusively for poetry, is represented by an excellent publication issued weekly at Benares by Bābū Harish-Chandra, entitled *Kabi-bachan-Sudhā*, or "Ambrosia of the Words of Poets." In this will be found much good original work, and a vast quantity of old Hindi poetry now for the first time published. The translations of the *Mahābhārata* and *Harivansa*, made by Pandit Gokulnāth of Benares, and printed at Calcutta in 1829, deserve mention; and one of the most important collections of Hindi poetry, the *Rāg-Kalpadrum* of Krishnānand Vyāsadev Rāg-Sāgar, was printed at the same place in 1842-45 in an immense volume of 1800 pages.

English education has naturally had a vast influence on modern vernacular literature, though not wholly a beneficial one. More than a half of the new works issued within the last thirty years are translations or adaptations from English; the journals, the great popularizers of new ideas, take their matter chiefly from English newspapers; the courts, where Urdū has since 1832 become the official language, contribute to the spread of the stiff and difficult phraseology of the Acts of the legislature, as different from the natural idiom of the people as can well be imagined. Literature in India has always owed much to the fostering influence of Government. It has been seen how the schools of Dehli and Lakhnau rose and declined with the fortunes of the Mughal empire and the kingdom of Oudh, and how that of Calcutta similarly owed its existence to British initiative. At the present day the patronage of the rulers of India is no less influential in determining the course of literary activity. Poetical composition is little practised, both because of the exhaustion of its themes and the little appreciation which it meets with from Europeans. More solid studies, politics, science, philosophy, morals, history, and especially controversial theology, are the topics now in favour; and, though much that is published is of the slightest possible intrinsic value, the resources of the language are being gradually cultivated and enlarged to meet the needs of the day. There is thus no reason to doubt that Hindostan will in time possess a body of literature worthy of the flexible and expressive speech of its people, and reflecting faithfully the standard of culture which it owes to its Western rulers. (C. J. L.)

HINGANGHĀT, a town in the Wardha district, Central Provinces, India, 21 miles S.W. of Wardha, in 20° 33' 30" N. lat., and 78° 52' 30" E. long., with a population in 1877 of 9415. It is a main seat of the cotton trade, the Hinganghāt cotton produced in the rich Wardha valley being esteemed one of the best indigenous staples of India. The principal native traders are Mārwarīs, many of whom have large transactions and export on their own account; but the

greater number merely act as middle-men between the cultivators and the large merchants. The municipal committee have opened a large gravelled market-place and storage-yard, with raised platforms, and scales for weighing the cotton. The place consists of Old and New Hinganghát,—the former, a straggling town, liable to be flooded by the river Waná ; the latter, in which the better classes reside, laid out in broad streets and avenues.

HINOJOSA DEL DUQUE, a town of Spain, in the province of Cordova, from which city it is distant about 58 miles N. by W. The manufacture of linens and woollens is carried on to some extent : the population is estimated at about 8500 :

HINTON, JAMES (1822–1875), aural surgeon and author, son of John Howard Hinton, Baptist minister and author of the *History and Topography of the United States* and other works, was born at Reading in 1822. He was educated at his grandfather's school near Oxford; and at the Nonconformist school at Harpenden, and in 1838, on his father's removal to London, was apprenticed to a woollendruaper in Whitechapel, where he came into contact with a phase of human life in its miserable and degraded forms which influenced powerfully the whole cast of his after thought. After retaining this situation about a year he became clerk in an insurance office. The most of his evenings were spent by him in intense study, and this, joined to the ardour, amounting to morbidness, of his interest in moral problems, so affected his health that in his nineteenth year he resolved to seek refuge from his own thoughts by running away to sea. His intention having, however, been discovered, he was sent, on the advice of the physician who was consulted regarding his health, to St Bartholomew's Hospital to study for the medical profession. After receiving his diploma in 1847, he was for some time assistant surgeon at Newport, Essex, but the same year he went out to Sierra Leone to take medical charge of the free labourers on their voyage thence to Jamaica, after which his interest in their welfare prompted him to remain a year on the island. After his return to England in 1850, he entered into partnership with a surgeon in London, where he soon had his interest awakened specially in aural surgery, and gave also much of his attention to physiology and to problems bearing on the relation between mind and body. In his practice he became convinced that in the immense majority of cases of ill-health it was the hope of cure rather than the drug that effected the remedy, a fact which explained to him much of the success of homœopathy, and induced him to lay the principal stress on moral methods of cure. He made his first appearance as an author in 1856 by contributing a series of papers on physiological and ethical subjects to the *Christian Spectator*; and the success of his work *Man and his Dwelling Place*, which appeared in 1858, determined him, notwithstanding that he had married in 1852, to give up his medical practice in order to devote his whole attention to writing on those practical moral problems which chiefly occupied his thoughts. A series of papers entitled "Physiological Riddles," which he contributed to the *Cornhill Magazine*, and afterwards published under the title *Life in Nature*, as well as another series entitled *Thoughts on Health*, written for the same periodical and collected and published separately in 1871, gave evidence of great aptitude in popular scientific exposition; but his interest in speculation was too absorbing to permit him to apply himself with sufficient pertinacity to literary work, and after a year's trial of it he found it necessary to resume his profession. In 1863 he obtained the appointment of aural surgeon to Guy's Hospital, after which he speedily acquired a lucrative west-end practice, and the reputation of being the most skilful aural surgeon of his day, a reputation fully borne

out by his works, *An Atlas of Diseases of the Membrana Tympani* and *Questions of Aural Surgery*, which are regarded as the chief authorities in this branch of surgery. The skill he had now obtained in his profession seemed to justify him in 1869 in resuming his philosophical studies, but the mental excitement thus produced, added to his professional labours, appears to have inflicted permanent injury on his brain; and, although by giving up his practice in 1874 he obtained partial relief, he began to suffer from sleeplessness and depression, and died of acute inflammation of the brain, 16th December 1875.

In addition to the works already mentioned, Hinton was the author of the *Mystery of Man*, and *The Place of the Physician*. On account of their fresh and vigorous discussion of many of the important moral and social problems of the time, his writings have had a wide circulation on both sides of the Atlantic. He contributed also several papers to the *Contemporary Review* and other periodicals. His *Life and Letters*, edited by Ellice Hopkins, with an introduction by Sir W. W. Gull, appeared in 1878.

HIOGO, or FIOGO, a seaport town of Japan, in the island of Nipon and province of Setsu, on the western shore of the Idzumi Sea, or Bay of Osaka, about 40 miles S.W. of Kioto, with which it has had railway communication since 1874. It was opened to foreign commerce in 1860, and since that date it has risen with the maritime suburb of Kobe (the Gate of God) to be a place of 50,000, or according to other authorities, 80,000 or 90,000 inhabitants. Its harbour, formerly dangerous, has by the construction of a costly breakwater been rendered one of the most serviceable in the kingdom. The best anchorage is found in front of Kobe, which has been chosen as the locale of the foreign settlement. Since the opening of the port great improvements have been effected in the native town, and the value of land and house property has greatly increased. The settlement, which consists of 162 lots, has been regularly laid out; its streets are macadamized and lighted with gas; and it possesses a bank, municipal buildings, and the largest warehouses yet erected by foreigners on Japanese soil. There is a recreation ground open to both natives and foreigners, with a cricket field and a croquet lawn. The population of the settlement was 169 in 1876; that of Kobe in 1874 was upwards of 8500. The trade of Hiogo consists mainly in the exportation of tea (1,599,199 dollars in 1877), silk, copper, camphor, wax, tobacco, ginseng, isinglass, and dried fish, and the importation of European manufactured goods—woollens, cotton, glass, &c. Most of the tea goes to New York, very little to London. The total value of the imports in 1874, 1875, 1876, and 1877 was respectively 6,030,239, 5,354,917, 3,748,967, and 4,313,641 dollars (the dollar being worth about 4s.), and the corresponding figures for the exports were 4,956,724, 2,813,102, 3,401,230, and 4,518,570. The industrial establishments comprise a shipbuilding yard, an iron-foundry, and a factory for the manufacture of paper pulp or "half stuff." There is a busy traffic maintained by ferry steamers between Hiogo and Osaka. The number of foreign ships that entered and cleared from the port in 1875 was 335, with a burden of 453,958 tons.

Hiogo was built in the days of the glory of the Taira family, and its name is equivalent to arsenal. At Minato Gawai near Kobe a small temple marks the spot where Kusunoki Masashige, the mirror of Japanese loyalty, met his death; and in Kobe itself there is a temple erected on the site of the ancient fauce built by Jingu Kogo on her return from Corea.

HIIPARCHIUS, the founder of mathematical astronomy, was born at Nicæa in Bithynia. The years of his birth and death are both unknown, but the period of his activity, according to the evidence of his observations, which have been preserved by Ptolemy, must have been between 160 and 125 n.c. Of his writings only one has come down to us, *Τῶν Ἀράτου καὶ Ἐυδόξου φαινόμενων ἐξηγήσεων βιβλία γ'*, published by Vittorioso at Florence, 1567, and by

Petavins in his *Uranologia*, Paris, 1630. For a notice of his discoveries see ASTRONOMY, vol. ii. p. 749.

HIPPEL, THEODOR GOTTLIEB VON (1741-1796), a German author, known chiefly as a humorist, was born on the 31st January 1741, at Gerdaunen in East Prussia, where his father was rector of a school. In his sixteenth year he went to Königsberg to study theology; but through the influence of the Dutch councillor of justice, Woyt, he was induced to devote himself to jurisprudence. A Russian lieutenant, Von Keyser, whose acquaintance he made in Königsberg, took him in 1760 to St Petersburg, where he might have had a brilliant career had not his love for his country made it impossible for him to live away from it. Returning to Königsberg he became a tutor in a private family; but, falling in love with a young lady of high position, he, as the readiest means of enabling him to marry her, gave up his tutorship and devoted himself with enthusiasm to legal studies. He was successful in his profession, passing from one grade to another, until in 1780 he was appointed burgomaster and director of police in Königsberg, and in 1786 privy councillor of war and president of the town; as he rose in the world, however, his inclination for matrimony vanished, and the lady who had stimulated his ambition was forgotten. To write books in his country house near Königsberg was his favourite amusement, and some of them have still a certain popularity. Perhaps the best known is his *Ueber die Ehe* (Concerning Marriage). He has also works on *The Social Improvement of Woman*, and on *Female Education*. Another curious book of his is *Lebensläufe nach aufsteigender Linie, nebst Beilagen A, B, C* (Careers according to an ascending line, with supplements A, B, C). His name is attached to several political writings of a satirical turn, and he was the author of a comedy *Der Mann nach der Uhr*, which was fortunate enough to win the applause of Lessing. Hippel was a friend of Kant, who admired his ingenuity and resource in forming and executing plans. Before the publication of Kant's *Kritik*, Hippel was made familiar with its main conclusions, and in his *Lebensläufe* he did his utmost to prepare the way for their reception. In nearly all his writings he had a serious purpose, but disliking a cold, systematic style, he communicated his ideas in what he intended to be a light and witty form. Much of his wit is rather crude, but he gave sufficient evidence of a lively fancy to justify his success as an author. His private character presented some curious contrasts. He shared the enthusiasm of his age for passionate friendships, but none of his friends were treated with confidence; endowed with a clear and penetrating intellect, he had a strong tendency to superstition; he seemed to have generous sympathies, yet his conduct was often hard and selfish; and although he incessantly praised simplicity of life, no one could be more fond of pomp and show. He died on the 23d April 1796, leaving a considerable fortune. In 1827-38 a collected edition of his works in 14 vols. was issued at Berlin.

HIPPO. See BÔNE.

HIPPOCAMPUS, or SEA-HORSE. The small fishes thus named constitute, together with the Pipe-fishes or *Syn-gnathi*, a distinct order of the class of fishes, that of Lophobranchs or fishes with the gills arranged in tufts. The name "Sea-horse" has been given from the singular horselike shape of the head and fore-part of the body. The head is compressed, and is prolonged into a flat snout, at the end of which opens the small mouth. The eye occupies the same position as in the horse, and the head is joined at an angle to a narrow and curved neck, which posteriorly is dilated into the broader body. As in all the fishes of this order, the body is not covered with soft

skin or scales, but encased in a mail composed of hard and tough scutes, which are of a more or less quadrangular shape, and generally armed with tubercles or spines. The tail is long, flexible, and prehensile, without caudal fin. These fishes are very bad swimmers, their locomotion being

Phyllopteryx eques, attached to sea-weed.

entirely dependent on the long dorsal fin which slowly propels them by a rapidly undulating screw-like motion; placed in the middle of the back of a body which generally occupies a vertical or oblique position in the water, this organ of locomotion has a propelling power far inferior to that of a terminal caudal fin. By means of their prehensile tail the sea-horses attach themselves to the stems of sea-weed or corals, which they resemble so closely in their outward appearance that it is difficult to distinguish them,—a resemblance which is still more increased in a group of sea-horses (*Phyllopteryx*) in which many of the spines and tubercles bear long tapering bands like the fronds of sea-weeds. Originally littoral fishes, sea-horses are, nevertheless, frequently found in mid-ocean, attached to floating substances on which they are carried away by currents far from their native shore. In the Sargasso Sea they are common. Like the other Lophobranchs, they take care of their progeny till the young have attained sufficient size and strength to shift for themselves. The male receives the eggs immediately after oviposition in a pouch situated on the lower part of his tail, where they are hatched, and where indeed the young remain until hunger compels them to leave their parent in search of food. More than twenty different species are known from the tropical and the warmer parts of the temperate zones. They are all of small size; that seen in our aquaria is the *Hippocampus antiquorum*, common on many parts of the French coast and farther south.

HIPPOCRATES, termed the "Father of Medicine," was born, according to Soranus, in Cos, in the first year of the 80th Olympiad, *i.e.*, in 460 B.C. He was a member of the family of the Asclepiadæ, and was believed to be either the nineteenth or seventeenth in direct descent from Æsculapius. It is also claimed for him that he was descended from Hercules through his mother, Phænarete. He studied medicine under Heraclides, his father, and Herodicus of Selymbria; in philosophy Gorgias of Leontini and Democritus of Abdera were his masters. His earlier studies were prosecuted in the famous Asclepion of Cos, and probably also at Cnidos. He travelled extensively, and taught and practised his profession at Athens, probably also in Thrace, Thessaly, Delos, and his native island. He died at Larissa in Thessaly, his age being variously stated as 85, 90, 104, and 109. The incidents of his life are shrouded by uncertain traditions, which naturally sprang up in the absence of any authentic record; the earliest biography was by one of the Sorani, probably Soranus the younger of Ephesus, in the

2d century; Suidas, the lexicographer, wrote of him in the 11th, and Tzetzes in the 12th century. In all these biographies there is internal evidence of confusion; many of the incidents related are elsewhere told of other persons, and certain of them are quite irreconcilable with his character, so far as it can be judged of from his writings and from the opinions expressed of him by his contemporaries; we may safely reject, for instance, the legends that he set fire to the library of the temple of health at Cnidos, in order to destroy the evidence of plagiarism, and that he refused to visit Persia at the request of Artaxerxes Longimanus, during a pestilential epidemic, on the ground that he would in so doing be assisting an enemy. He is referred to by Plato (*Protag.*, p. 283; *Phædr.*, p. 211) as an eminent medical authority, and his opinion is also quoted by Aristotle. The veneration in which he was held by the Athenians serves to dissipate the calumnies which have been thrown on his character by Andreas, and the whole tone of his writings bespeaks a man of the highest integrity and purest morality.

Born of a family of priest-physicians, and inheriting all its traditions and prejudices, Hippocrates was the first to cast superstition aside, and to base the practice of medicine on the principles of inductive philosophy. It is impossible to trace directly the influence exercised upon him by the great men of his time, but one cannot fail to connect his emancipation of medicine from superstition with the widespread power exercised over Greek life and thought by the living work of Socrates, Plato, Æschylus, Sophocles, Euripides, Herodotus, and Thucydides. It was a period of great intellectual development, and it only needed a powerful mind such as his to bring to bear upon medicine the same influences which were at work in other sciences. It must be remembered that his training was not altogether bad, although superstition entered so largely into it. He had a great master in Democritus, the originator of the doctrine of atoms, and there is every reason to believe that the various "asclepiæ" were very carefully conducted hospitals for the sick, possessing a curious system of case-books, in the form of votive tablets, left by the patients, on which were recorded the symptoms, treatment, and result of each case. He had these records at his command; and he had the opportunity of observing the system of training and the treatment of injuries in the gymnasia. One of his great merits is that he was the first to dissociate medicine from priestcraft, and to direct exclusive attention to the natural history of disease. How strongly his mind revolted against the use of charms, amulets, incantations, and such devices appears from his writings; and he has expressly recorded, as underlying all his practice, the conviction that, however diseases may be regarded from the religious point of view, they must all be scientifically treated as subject to natural laws (*De Aere*, 29). Nor was he anxious to maintain the connexion between philosophy and medicine which had for long existed in a confused and confusing fashion.¹ His knowledge of anatomy, physiology, and pathology was necessarily defective, the respect in which the dead body was held by the Greeks precluding him from practising dissection; thus we find him writing of the tissues without distinguishing between the various textures of the body, confusing arteries, veins, and nerves, and speaking vaguely of the muscles as "flesh." But when we come to study his observations on the natural history of disease as presented in the living subject, we recognize at once the presence of a great clinical physician. Hippocrates based his principles and practice on the theory of the existence of a spiritual restoring essence or principle, *φύσις*, the *vis medicatrix naturæ*, in the management of which the art of the physician consisted. This art could, he held, be only obtained by the application of experience, not only to disease at large, but to disease in the individual. He strongly deprecated blind empiricism; the aphorism "*ἡ πείρα σφαλερῆ, ἢ κρίσις χαλεπῆ*" (whether it be his or not), tersely illustrates his position. Holding firmly to the principle, *νοῦσαν φύσις ἰητροί*, he did not allow himself to remain inactive in the presence of disease; he was not a merely "expectant" physician; as Sydenham puts it, his practice was "the support of enfeebled and the coercion of outrageous nature." He largely employed powerful medicines and blood-letting both ordinary and by cupping. He advises, however, great caution in their application. He placed great dependence on diet and regimen, and here, quaint as many of his directions may now sound, not only in themselves, but in the reasons given, there is much which is still adhered to at the present day. His treatise *Περὶ ἀέρων, ὑδάτων, καὶ τόπων* (*Airs,*

Waters, and Places) contains the first enunciation of the principles of public health. Although the treatises *Περὶ κρίσεων* cannot be accepted as authentic, we find in the *Προγνώστικόν* evidence of the acuteness of observation in the manner in which the occurrence of critical days in disease is enunciated. His method of reporting cases is most interesting and instructive; in them we can read how thoroughly he had separated himself from the priest-physician. Laennec, to whom we are indebted for the practice of auscultation, freely admits that the idea was suggested to him by study of Hippocrates, who, treating of the presence of morbid fluids in the thorax, gives very particular directions, by means of succussion, for arriving at an opinion regarding their nature. Laennec says, "Hippocrate avait tenté l'auscultation immédiate." Although the treatise *Περὶ νοῦσαν* is doubtfully from the pen of Hippocrates, it contains strong evidence of having been the work of his grandson, representing the views of the Father of Medicine. Although not accurate in the conclusions reached at the time, the value of the method of diagnosis is shown by the retention in modern medicine of the name and the practice of "Hippocratic succussion." The power of graphic description of phenomena in the Hippocratic writings is illustrated by the retention of the term "facies Hippocratica," applied to the appearance of a moribund person, pictured in the *Prognostics*. In surgery his writings are important and interesting, but they do not bear the same character of caution as the treatises on medicine; for instance, in the essay *On Injuries of the Head*, he advocates the operation "of trephining" more strongly and in wider classes of cases than would be warranted by the experience of later times.

The *Hippocratic Collection* consists of eighty-seven treatises, of which a part only can be accepted as genuine. The collection has been submitted to the closest criticism in ancient and modern times by a large number of commentators. (For full list of the early commentators, see Adams's *Genuine Works of Hippocrates*, Sydenham Society, vol. i. pp. 27, 28.) The treatises have been classified according to (1) the direct evidence of ancient writers, (2) peculiarities of style and method, and (3) the presence of anachronisms and of opinions opposed to the general Hippocratic teaching,—greatest weight being attached to the opinions of Erotian and Galen. The general estimate of commentators is thus stated by Adams:—"The peculiar style and method of Hippocrates are held to be conciseness of expression, great condensation of matter, and disposition to regard all professional subjects in a practical point of view, to eschew subtle hypotheses and modes of treatment based on vague abstractions." The treatises have been grouped in the four following sections:—(1) genuine; (2) those consisting of notes taken by students and collected after the death of Hippocrates; (3) essays by disciples; (4) those utterly spurious. Littré accepts the following thirteen as absolutely genuine:—(1) *On Ancient Medicine* (*Περὶ ἀρχαίας ἡτρικῆς*); (2) *The Prognostics* (*Προγνώστικόν*); (3) *The Aphorisms* (*Ἀφορισμοί*); (4) *The Epidemics*, i. and iii. (*Ἐπιδημιῶν α' καὶ γ'*); (5) *On Regimen in Acute Diseases* (*Περὶ διαίτης ἀξέων*); (6) *On Airs, Waters, and Places* (*Περὶ ἀέρων, ὑδάτων, καὶ τόπων*); (7) *On the Articulations* (*Περὶ ἄρθρων*); (8) *On Fractures* (*Περὶ ἀγμάτων*); (9) *The Instruments of Reduction* (*Μοχλικός*); (10) *The Physician's Establishment, or Surgery* (*Κατ' ἰητροίον*); (11) *On Injuries of the Head* (*Περὶ τῶν κεφαλῆ τραυμάτων*); (12) *The Oath* (*Ὅρκος*); (13) *The Law* (*Νόμος*). Of these Adams accepts as certainly genuine the 2d, 6th, 5th, 3d (7 books), 4th, 7th, 8th, 9th, and 12th, and as "pretty confidently acknowledged as genuine, although the evidence in their favour is not so strong," the 1st, 10th, and 13th, and, in addition, (14) *On Ulcers* (*Περὶ ἐλκῶν*); (15) *On Fistula* (*Περὶ συργγῶν*); (16) *On Hemorrhoids* (*Περὶ αἰμορροΐδων*); (17) *On the Sacred Disease* (*Περὶ ἱερῆς νοῦσαν*). According to the sceptical and somewhat subjective criticism of Ermerins, the whole collection is to be regarded as spurious except *Epidemics*, books i. and iii. (with a few interpolations), *On Airs, Waters, and Places*, *On Injuries of the Head* ("insigne fragmentum libri Hippocratei"), the former portion of the treatise *On Regimen in Acute Diseases*, and the "obviously Hippocratic" fragments of the *Coan Prognostics*. Perhaps also the *Oath* may be accepted as genuine; its comparative antiquity is not denied. The *Aphorisms* are certainly later and inferior. In the other non-Hippocratic writings Ermerins thinks he can distinguish the hands of no fewer than nineteen different authors, most of them anonymous, and some of them very late.

The earliest Greek edition of the Hippocratic writings is that which was published by Aldus and Asulanus at Venice in 1526 (folio); it was speedily followed by that of Frobenius, which is much more accurate and complete (fol., Basel, 1533). Of the numerous subsequent editions, probably the best was that of Forsius (Frankfort, 1595, 1621, Geneva, 1657), until the publication of the great works of Littré, *Œuvres complètes d'Hippocrate, traduction nouvelle avec le texte grec en regard, collationnée sur les manuscrits et toutes les éditions, accompagnée d'une introduction, de commentaires médicaux, de variantes, et de notes philologiques* (10 vols. Paris, 1839-61), and of F. Z. Ermerins, *Hippocratis et aliorum*

¹ "Hippocrates Cōns, primus quidem ex omnibus memoria dignus, ab studio sapientiæ disciplinam hanc separavit, vir et arte et facundia insignis" (Celsus, *De Medicina*).

medicorum veterum reliquiae (3 vols., Utrecht, 1859-64). See also Adams (as cited above), and Reinhold's *Hippocrates* (2 vols., Athens, 1864-67). Darenberg's edition of the *Œuvres choisies* (2d ed., Paris, 1855) includes the *Oath*, the *Law*, the *Prorrhotics*, book i., the *Prognostics*, *On Airs, Waters, and Places*, *Epidemics*, books i. and iii., *Regimen*, and *Aphorisms*. Of the separate works attributed to Hippocrates the editions and translations are almost innumerable; of the *Prognostics*, for example, seventy editions are known, while of the *Aphorisms* there are said to exist as many as three hundred. For some notice of the Arabic, Syriac, and Hebrew translations of works professedly by Hippocrates (Ibukrat or Bukrat), the number of which greatly exceeds that of the extant Greek originals, reference may be made to Flügel's contribution to the article "Hippokrates" in the *Encyclopädie* of Ersch and Gruber. They have been partially catalogued by Fabricius in his *Bibliotheca Græca*. (J. B. T.)

HIPPOLYTUS, an ecclesiastical writer belonging to the first half of the 3d century. Of the details of his life little that is authentic is known. He appears to have been born in the latter half of the 2d century. From the fact that he employs Greek as his mother tongue, it has been supposed that he belonged to the eastern portion of the Roman empire; but this conclusion is by no means stringent, and there are various indications in his writings that he had passed some at least of his early years in Rome. On the apparently trustworthy authority of Photius (cod. 121), he is believed to have been while still a youth a personal disciple of Irenæus, perhaps in Rome, but most likely in Lyons. By inference from the vivid minuteness with which he relates details of the personal history of Callistus in the 9th book of his *Refutation* he is believed to have been in Rome from the beginning of the episcopate of Victor (189-199). It is certain that in the early years of the 3d century he was stationed in that city as a presbyter conspicuous for energy, zeal, eloquence, and learning. He was a prominent defender of Victor's view on the much vexed Paschal controversy, but came into collision with Victor's successors, Zephyrinus and Callistus, on several questions of ecclesiastical dogma and discipline. As regarded the relation between the Father and the Son in the Trinity, for example, Hippolytus defended what is known as subordinatism against the patripassianism of the bishops, he accusing them of Noctianism while they retorted upon him with a charge of ditheism. Again, in the dispute as to whether the lapsed could ever be lawfully restored to the fellowship of the church visible, Hippolytus took the severer and Callistus the milder view. So also on the subject of clerical marriages. From his own language in the 9th book of the *Refutatio*, combined with his designation of himself in the poem, it appears that Hippolytus ultimately came to occupy in Rome the position of a bishop (cf. Euseb., *H. E.*, vi. 20), although not in communion with the "Catholic" party; and the difficulty of reconciling this with the strong evidence we have that Portus (*i. e.*, the Roman harbour opposite Ostia, and not Portus Romanorum or Aden, as Le Moine and others founding upon a misunderstanding of Eusebius, have conjectured) was the scene of his activity is probably best got over if we assume that as dissenting bishop he undertook the episcopal superintendence of his adherents in both places, but took his title from the smaller. As regards the close of his life our most trustworthy information is derived from the chronographer of 354 (Mommsen, *Ueber den Chronographen vom Jahre 354*, Leipzig, 1850), according to whom "the presbyter" Hippolytus in the time of Alexander Severus (235) was banished along with the Roman bishop Pontianus to Sardinia, where, it seems to be suggested, he died.

In 1551 a marble statue of Hippolytus "Portuensis," of uncertain date but not later than the 5th century, was dug up in Rome; it is now to be seen in the Vatican. He is represented as seated upon an episcopal throne, wearing the Greek pallium, over which the Roman toga is thrown. On the sides of the throne is inscribed in Greek the rude Easter Cycle of which he is known to have been the author; behind is given an imperfect list of his numerous works. The

catalogues given by Eusebius, Jerome, and Nicephorus differ slightly in details; but all bear witness to his diligence as a writer. The extant fragments were first collected by Fabricius (*Hippolyti Opera gr. et lat.*, 2 vols. fol., Hamburg, 1716-18), and were afterwards reprinted by Gallaud in the second volume of his *Bibliotheca Veterum Patrum* (1766). See also Migne, *Curs. Patr. Gr.*, vol. x. They include fragments of commentaries on various books of Scripture, a treatise "On Christ and Antichrist," an "expository" (*ἀποδεικτική*) discourse "To the Jews," a fragment "To the Greeks" or "On the Universe," tracts "Against Noetus," "Against Beron and Helix," and "On the Holy Theophany," fragments of homilies (in which kind of composition he particularly excelled), and a few short quotations preserved by the author of the *Chronicon Paschale*. The appendix in Fabricius, containing doubtful or spurious pieces, includes "A Discourse on the End of the World, and on Antichrist, and on the Second Coming of our Lord Jesus Christ," also a short account of the twelve apostles, stating where each of them laboured and where each of them died, a list of the seventy apostles, heads of the canons of Abulides or Hippolytus as used by the Ethiopian Christians, and the canons of the Church of Alexandria. Of the spuriousness of the last mentioned at least there can be no doubt. A new interest in Hippolytus as an ecclesiastical writer was awakened among scholars about 1851 in connexion with his *Omniium Hæresium Refutatio*, which has an interesting history. As an anonymous MS. of the 14th century it had in 1842 been brought among various other manuscripts from Mount Athos to Paris by Minoïdes Mynas, a learned Greek who had been commissioned by the French Government to search for such treasures, and had been deposited in the great national library where it was registered as a work *On all Heresies*. It failed for some time to attract any special notice; but the attention of M. Emmanuel Miller, an official of that institution, having been at length excited by some fragments of Pindar and of an unknown lyric poet which it contained, he was led to examine it more closely and to adopt the conclusion that it was the continuation of the fragment entitled *Philosophumena*, printed in the Benedictine edition of Origen as the work of that author. Under this persuasion he offered it for publication to the university of Oxford, from whose press it appeared in 1851 under his editorship, bearing the title *Origenis Philosophumena; sive Omniium Hæresium Refutatio*. It was at once welcomed by the learned world as a literary treasure of singular value; but it was almost immediately perceived that, though Miller had certainly judged rightly in affirming it to be a continuation of the fragmentary *Philosophumena*, he had as certainly erred in attributing its composition to Origen, whose authorship of the previously known portion had already been disputed by Huet, Henmann, and Gale. By Jacobi and Duncker in 1851, who were speedily followed by Gieseher, Bunsen, Wordsworth, and Dollinger, it was with increasing confidence claimed for Hippolytus, to whom it is now attributed with almost entire unanimity by critics,—the arguments of Baur (*Theol. Jahrb.*, 1853) in favour of the presbyter Caius, and still more those of Armellini (*De prisca refutatione hæresion*, Rome, 1863) in favour of Novatian, having been found to be quite unconvincing. Originally it consisted of ten books, of which, however, only eight survive, namely, the first and the fourth to the tenth inclusive; Book i. gives an account of the different schools of ancient philosophy—Greek, Indian, and Druidical; books ii. and iii. appear to have dealt with the doctrines and mysteries of the Egyptians and Chaldeans respectively; book iv. (which is slightly defective at the commencement) treats of Chaldean horoscopy and Egyptian theurgy; books v.-ix. dispose of the various heresies which had asserted themselves within the Christian Church. These are taken up in chronological order and arranged in five main groups, the Ophite, Simonist, Basilidean, Valentinian or Doctetic, and Noctian. Whether they be regarded as attempts to Christianize paganism, to conciliate Judaism, or to gnosticize Christianity, their unscriptural character is invariably insisted on. The entire work is summarized in book x. The value of the *Refutatio* as a whole, in its bearing on the history of the apostolic and subapostolic ages, and on the critical problems arising out of that history, can hardly be overestimated.

Since its first publication by Miller (Oxford Clarendon Press, 1851) it has been edited by Lagarde (*Hippolyti Romani quæ feruntur omnia Græce*, Göttingen, 1858), by Duncker and Schneidewin, (Göttingen, 1859), and by Cruice (Paris, 1860). The *Refutatio* as well as the other extant *Works and Fragments* of Hippolytus are to be met with in an English translation in the "Ante-Nicene Christian Library" (Edin., 1868-9).

See Bunsen, *Hippolytus and his Age* (1852; 2d ed. 1854; Germ. ed., 1853); Dollinger, *Hippolytus u. Kallistus* (1853; Engl. transl., Edin., 1876); Wordsworth, *St Hippolytus and the Church of Rome in the Third Century* (1853); Cruice, *Études sur de nouveaux documents historiques empruntés au livre des Philosophumena et relatifs au commencement des hérésies chrétiennes* (1853); Volkmar, *Hippolytus u. die römische Zeitgenossen* (1855); Lipsius, *Zur Quellenkritik des Epiphanius* (1865), and *Quellen der ältesten Ketzergeschichte* (1875); Harnack, *Zur Quellenkritik der Geschichte des Gnosticismus* (1873-74). Lipsius and Harnack occupy themselves largely with the question as to the relation between the *Refutatio* and a shorter treatise which can be shown to have formed the basis of the works of Epiphanius and Philaster. See also Jacobi, art. "Hippolytus," in Herzog-Plitt's *Real-Encyclopädie* (1880).

HIPPOLYTUS, St, according to the Roman breviary, was one of St Lawrence's converts, who, when summoned before the emperor Valerian on account of the practice of his religion, made a public profession of Christianity. First beaten with rods, he was finally delivered over along with all his family to death, the mode of execution in his case being similar to that by which Hippolytus the son of Theseus perished. The mythical character of this legend, which, however, can in part be traced as far back as to Prudentius (*Hym.* 11), is recognized by Döllinger (see his *Hippolytus u. Kallistus*, chap. ii.). This saint, along with Casianus, is commemorated by the Roman Church on August 13. He is the patron of Mexico.

HIPPONAX, of Ephesus, a poet placed third, after Archilochus and Simonides, among the classic iambic poets of Greece. Expelled from Ephesus in 540 B.C. by the tyrants Athenagoras and Comas, he took refuge in Clazomenæ. There his deformed figure and malicious disposition exposed him to the caricature of the Chian sculptors Bupalus and Athenis; and he revenged himself by issuing against them a series of satires. These, though keen and bitter, are in thought and execution much inferior to the similar works of his predecessor Archilochus. His coarseness of thought and feeling, his rude vocabulary, his want of grace and taste, and his numerous allusions to matters of merely local interest prevented his becoming a favourite in Attica. He invented epic parody, and the four opening lines of a parody on the *Iliad* have been preserved in Athenæus (xv. 698 B). He was also the inventor of a peculiar metre, used after him by many writers, called the *scaron* or *choliambus*, which substitutes a spondee for the final iambus of an iambic senarius. His works, which were annotated by Hermippus of Smyrna, were at an early date mingled and confused with those of Ananius, for whom some even claim the invention of the choliambus.

HIPPOPOTAMUS, a family (*Hippopotamidae*) of artiodactyle ungulate mammals comprising two genera, each containing a single living species. Of these the best known is the hippopotamus (*Hippopotamus amphibius*), occurring

Hippopotamus.

only in Africa, where it abounds in many of the river courses. It is a huge unwieldy creature, measuring in the largest specimens fully 14 feet from the extremity of the upper lip to the tip of the tail, while it ordinarily attains a length of 12 feet, with a height of 5 feet at the shoulders, and a girth round the thickest part of the body almost equal to its length. Its remarkably small ears are exceedingly flexible, and are kept in constant motion when the animal is seeking to catch a distant sound. Its eyes are placed high up on the head, and but little below the level of the ears; its gape is wide and its upper lip thick and

bulging so as to cover over even the largest of its teeth when the mouth is closed. It is provided with a considerable number of molar teeth adapted for grinding vegetable substances, and a formidable array of long spear-like incisors and curved chisel-edged canines or tusks which, according to Baker, root up the rank grass like an agricultural implement. Its legs are short, so that the body is but little elevated above the ground; and its feet, which are small in proportion to the size of the animal, terminate in four short toes each bearing a small hoof. With the exception of a few tufts of hair on the lips, on the sides of the head and neck, and at the extremity of the short robust tail, the skin of the hippopotamus, some portions of which are 2 inches in thickness, is entirely destitute of covering. It is usually of a dark fleshy red colour, irregularly marked with blackish spots. The hippopotamus is a gregarious animal, living in herds of from 20 to 40 individuals on the banks and in the beds of rivers, in the neighbourhood of which it most readily finds its appropriate food. This consists chiefly of grass and of aquatic plants, of which it consumes enormous quantities, the stomach of one of those creatures being capable of containing from 5 to 6 bushels. They feed principally by night, remaining in the water during the day, although in districts where they are little disturbed by man they are less exclusively aquatic. In such remote quarters they put their heads boldly out of the water to blow, but when rendered suspicious by man's persecution, they become exceedingly cautious in this respect, only exposing their nostrils above the water, and even this they prefer doing amid the shelter of water plants. In spite of their enormous size and uncouth form, they are expert swimmers and divers, and can, it is said, remain easily under the water from five to eight minutes. They are also said to walk with considerable rapidity on the bottoms of rivers, beneath at least a foot of water. At nightfall they come on land to feed; and when, as often happens on the banks of the Nile, they reach cultivated ground, they do immense damage to growing crops, destroying by their ponderous tread even more than they devour. To scare away those unwelcome visitors the natives in such districts are in the habit of kindling great fires at night. Although they do not willingly go far from the water on which their very existence depends, occasionally they have been found to travel long distances by night in search of food, and in spite of their clumsy appearance they are able, according to Baker, to climb up steep banks and precipitous ravines with astonishing power and ease. Of a wounded hippopotamus which that traveller once saw leaving the water and galloping inland, he says, "I never could have imagined that so unwieldy an animal could have exhibited such speed. No man could have had a chance of escape." The hippopotamus does not confine itself to rivers only, but when opportunity occurs of exercising choice it has been known to prefer the waters of the ocean as its home during the day. Of a mild and inoffensive disposition, it seeks to avoid collision with man; when wounded, however, or in defence of its young, it is wont to exhibit the greatest ferocity, and the native canoes are frequently capsized and occasionally demolished by its infuriated attacks, its usual bellowing grunt then becoming loud enough to be heard a mile away. As among elephants, so also among hippopotami there are "rogues"—old bulls which, having been expelled from the herd, have become soured in solitude; these are at all times dangerous. Assuming the offensive on every occasion, they attack all and sundry without shadow of provocation; the natives, therefore, are careful to avoid the haunts of those *solitaires*, which are usually well known.

The rifle of the European has proved the most potent destroyer of the hippopotamus; but to prove effective it

must be aimed at the head, the most vulnerable points in that region being immediately behind the ear and in the eye. Everywhere regarded as a valuable prize, the natives employ a variety of methods in order to secure it, the most common of these being the use of an iron harpoon attached to a line. Allowing themselves to float down stream on a raft, the hippopotamus hunters no sooner reach the sleeping herd than the expertest of them plunges his harpoon deep into the body of the selected victim. The light canoes are then launched from the raft, and with all speed the hunters make for the shore, bearing with them the line attached to the harpoon, which they further secure by giving it a turn round the trunk of a tree. Unable to free itself, the hippopotamus wastes its strength in impotent rage, its persecutors meanwhile assailing it with a shower of javelins under which its life blood gradually ebbs away, until at last it is hauled up dead or dying on the shore. Another native method of destroying these animals is by means of a trap known as the "downfall," consisting of a heavy wooden beam armed at one end with a poisoned spear-head and suspended by the other to a forked pole or overhanging branch of a tree. The cord by which the beam is suspended descends to the path beneath, across which it lies in such a manner as to be set free the instant it is touched by the foot of the passing hippopotamus; the beam thus liberated immediately descends, and the poisoned weapon passes into the head or back of the luckless beast, whose death in the adjacent stream takes place soon after. Such "downfalls" are placed over the paths by which the animals are in the habit of reaching their nightly feeding grounds. They are also occasionally taken by means of ordinary pitfalls, so dexterously concealed as often to entrap the unwary traveller. Although inferior in sagacity to the elephant, the hippopotamus is very far from being stupid, as is frequently proved by its remarkable adroitness in the discovery and avoidance of traps and pitfalls, as well as in its timely migration from localities which, owing to the prevalence of the rifle, have become no longer tenable. It is said to be possessed of a remarkably tenacious memory, so that, according to Sir Andrew Smith, when once it has been assaulted in its watery dwelling and injured through incautiously exposing itself, it will rarely be guilty of the same indiscretion a second time, even although a very long period should elapse before its haunts are revisited. The female is less in size than the male, and is exceedingly shy, taking to the water with her young, which she usually carries astride on her neck, on the slightest alarm. It is only after long practice that the young become able to remain as long under the water as their parents, and for this reason the females while tending them come much oftener to the surface than their own necessities require. The period of gestation, as observed in females confined in the Zoological Gardens of London and Paris, extends to nearly eight months; the young reach maturity in five years; and the full term of life in the species is believed to extend to thirty years. The male hippopotamus which recently (1878) died in the Zoological Gardens, London, was captured in August 1849 when

only a few days old; it had thus nearly attained the age of twenty-nine, while an examination of its dead body disclosed, says Professor Owen, "no special morbid appearance to suggest that death from old age had been anticipated" (*Annals and Magazine of Nat. Hist.*, September 1879). The flesh of the hippopotamus is generally considered a delicacy both by natives and colonists, although according to Livingstone there are certain tribes on the Zambesi who have as great an abhorrence of hippopotamus meat as Mahometans have of swine's flesh. The fatty matter lying between the skin and the muscles is one of the purest of animal fats, and was formerly in great request among the Cape colonists when as yet those amphibians abounded in the rivers of that colony. The skin of the hippopotamus is turned to profitable account in the manufacture of elastic whips, which are in great demand throughout the African continent. The skin, according to Schweinfurth, when fresh is cut into long quadrilateral stripes, which when half-dried are trimmed with a knife and afterwards hammered out, like iron on an anvil, into round whips. As several hundreds can be made from a single hide, that part is of considerable commercial value. Still more valuable are the tusks and incisor teeth, which, from their extreme hardness and the fact that they do not readily become yellow, are now largely used in the manufacture of artificial teeth. The hippopotamus formerly abounded in such rivers as the Nile, the Niger, the Senegal, and most of the rivers of South Africa. It is now, however, becoming gradually more restricted in its distribution, having disappeared altogether from the Egyptian Nile,—although still abundant in its Abyssinian tributaries,—as well as from the rivers of Cape colony.

The Liberian hippopotamus (*Chceropsis liberiensis*), the only other existing member of the family, is exceedingly rare, having been only known until recently from the two skulls on which the genus and species were founded. It differs from the common species in possessing only one pair of incisors in each jaw instead of two, and in several other minor points. A few years ago a young specimen of this rare species was brought alive to England from the Scarcies river, north of Sierra Leone, but it died soon after landing. The species is found on the west coast of Africa and on certain of the rivers flowing into Lake Chad.

Although there are thus only two living species, both of which are confined to Africa, the hippopotamus family was both larger and more widely distributed in former periods of the earth's history, fossil remains of at least nine species having been found in the Tertiary deposits of Europe and India. In Europe they occur as far north as Belgium and the south of England, but they are found nowhere in such abundance as in the island of Sicily, from which they were formerly exported in shiploads to England and France, where they were used in the manufacture of lamp-black and manure. The occurrence of these animals in a place which they could not possibly have reached had it always been an island, is regarded as one of the many proofs that dry land existed during some portion at least of the Tertiary period between Italy and Africa.
